INTERNATIONAL INSTITUTE OF AGRICULTURE
BUREAU OF AGRICULTURAL INTELLIGENCE AND PLANT DISEASES

INTERNATIONAL REVIEW OF THE SCIENCE AND PRACTICE OF AGRICULTURE

MONTHLY BULLETIN
OF AGRICULTURAL INTELLIGENCE AND PLANT DISEASES

YEAR XI - No. 1 JANUARY 1920

ROME
PRINTING OFFICE OF THE INSTITUTE
1920

THE INTERNATIONAL INSTITUTE OF AGRICULTURE

Origin of the Institute and Summary of the International Treaty.

The International Institute of Agriculture was established under the International Treaty of 7 June 1905, which was ratified by forty governments. Eighteen other governments have since adhered to the Institute.

It is a Government institution in which each country is represented by delegates. The Institute is composed of a General Assembly and a Permanent Committee.

The Institute, always confining its attention to the international aspect of the various questions concerned, shall:

(*a*) collect, study and publish as promptly as possible, statistical technical, or economic information concerning farming, vegetable and animal products, trade in agricultural produce, and the prices prevailing in the various markets;

(*b*) communicate the above information as soon as possible to those interested;

(*c*) indicate the wages paid for farm work;

(*d*) record new diseases of plants which may appear in any part of the world, showing the regions infected, the progress of the diseases, and if possible, any effective remedies;

(*e*) study questions concerning agricultural co-operation, insurance and credit from every point of view; collect and publish information which might prove of value in the various countries for the organization of agricultural co-operation, insurance and credit;

(*f*) submit for the approval of the various governments, if necessary, measures for the protection of the common interests of farmers and for the improvement of their condition, utilizing for this purpose all available sources of information, such as resolutions passed by international or other agricultural congresses and societies, or by scientific and learned bodies, etc.

Permanent Committee

of the International Institute of Agriculture

President : Marquis Raffaele Cappelli, *Delegate of Italy.*

Vice-President : M. Louis-Dop *Delegate of France.*

List of the Delegates of the Permanent Committee :

1	Abyssinia	V	Prof. G. Cuboni, Director, Station of Plant Pathology, Rome
2	Argentine Republic .	I	Dr. Octavio Piñeiro Sorondo.
3	Austria	I	Chev. V. de Pozzi, Government Councillor.
4	Hungary	I	. . . . .
5	Belgium	IV	O. Bolle.
6	Belgian Congo . . .	V	O. Bolle.
7	Brazil	I	D. de Campos, Commercial attaché to Embassy.
8	Bulgaria	III	M. Stancioff.
9	Chile	II	Filippe Aninat. Chargé d'affaires.
10	China	I	Wang-Tseng-Sze.
11	Colombia	V	Don Rufo Ruffo, Principe della Scaletta.
12	Costa-Rica.	V	P. Châtchong-Li, Secretary to Chinese Legation.
13	Cuba	V	M. A. Martin Rivero, Minister Plenipotentiary.
14	Denmark	IV	A. de Oldenburg, Chargé d'affaires.
15	Ecuador	V	M. Miguel Valverde, Consul Général.
16	Egypt	II	. . . . .
17	Ethiopia	V	Prof. G. Cuboni. Dir. of the St. of Pathol veg. of Rome.
18	France	I	Louis-Dop, Vice-President of the Institute.
19	French West Africa.	V	Louis-Dop.
20	Algeria	V	Louis-Dop.
21	Indo-China	V	Louis-Dop.
22	Madagascar	V	Louis-Dop.
23	Morocco	V	Louis-Dop.
24	Tunis	V	Louis-Dop.
25	Germany	I	Dr. T. Mueller, Privy Councillor.
26	Gt. Britain & Ireland	I	Sir Thomas Elliot, Bartt., K. C. B.
27	Australia	III	Sir Thomas Elliot, Bartt., K. C. B.
28	British India . . .	II	Sir Thomas Elliot, Bartt., K. C. B.
29	Canada	II	Sir Thomas Elliot, Bartt., K. C. B.
30	Mauritius.	V	Sir Thomas Elliot, Bartt., K. C. B.
31	New Zealand . . .	IV	Sir Thomas Elliot, Bartt., K. C. B.
32	Union of South Africa	IV	Sis Thomas Elliot, Bartt., K. C. B.
33	Greece	IV	M. Coromilas, Minister Plenipotentiary.
34	Guatemala	V	G. Montefiore, Consul General for Guatemala.
35	Italy	I	Marquis R. Cappelli, Senator, Pres. of the Institute.
36	Eritrea & It. Somalia	IV	Marco Besso.
37	Tripoli and Cirenaica	IV	Count Edoardo Soderini.
38	Japan	I	M. Hotta, Secretary to Embassy.
39	Luxembourg.	V	O. Bolle, Delegate of Belgium.
40	Mexico	III	. . . . .
41	Montenegro	V	G. Volpi, Minister Plenipotentiary.
42	Netherlands	IV	Baron W. B. R. de Welderen Rengers, Minister Plenip.
43	Dutch East Indies .	IV	Baron W. B. R. de Welderen Rengers.
44	Nicaragua	V	V. E. Bianchi, Consul General.
45	Norway	IV	Dr. A. Fjelstad, Counsellor to the Agricultural Department.
46	Ottoman Empire. . .	I	Dr. Mehmed Djémil Bey.
47	Paraguay	V	. . . . .
48	Persia	IV	A. del Gallo Marquis of Roccagiovine.
49	Peru	V	Louis-Dop, Delegate of France.
50	Portugal	IV	Eusebio Leao, Minister Plenipotentiary.
51	Roumania	I	A. E. Lahovary, Minister Plenip.
52	Russia.	I	His Excell. G. G. Zabiello Consul General for Russia.
53	Salvador	V	. . . . .
54	San Marino.	V	His Excell. L. Luzzatti, Minister of State.
55	Serbia	III	C. Scotti, Consul General for Serbia.
56	Spain	I	Francisco Bilbao Sevilla, Agricultural Engineer.
57	Sweden	IV	Baron C. N. D. De Bildt, Minister Plenipotentiary.
58	Switzerland	IV	M. Georgers Wagnière, Minister Plenipotentiary.
95	United States	I	. . . . .
60	Uruguay	V	Dr. E. Rovira, Consul.

Secretary General : Prof. Carlo Dragoni.

CONTENTS

III — Live stock and breeding.

a) General.

b) Special.

IV. — Farm Engineering.

V. — Rural Economics.

VI. — Agricultural Industries.

PLANT DISEASES.

III. — Diseases due to fungi, bacteria and other lower plants.

V. — Injurious insects and other lower animals.

IV. — PERIODICAL PUBLICATIONS REVIEWED BY THE BUREAU OF AGRICULTURAL INTELLIGENCE AND PLANT DISEASES. *

GENERAL INFORMATION

RURAL HYGIENE

1 - **Antagonism of Livestock and Man in the Blood Nutrition of *Anopheles maculipennis*. The Antimalarial Role of Domestic Cattle.** — ROUBEAU, E. in *Comptes rendus de l'Académie de Sciences*, Vol 169, No. 10, pp. 483-486. Paris, Sept. 8, 1919.

It is generally thought that anopheles seek nourishment not only from the blood of human beings but also from that of animals. Certain species of anopheles are found in uninhabited regions, peopled only by big game.

The *Anopheles maculipennis*, chief carrier of malaria in Europe, frequents mostly cow-sheds and stables. From observations made by the author, principally in the Vendée marshes, the Lower Loire and the neighbourhood of Paris, the following facts were ascertained : —

1. The *Anopheles maculipennis* bite in the interior of places occupied by man or domestic animals. It seeks first animals, exceptionally man.

2. The anopheles share each night, in order of preferance, the available animals of a district. The animals most sought after protect the others. In order of preference, mosquitoes seek in the first place pigs, then cattle, horses, goats, sheep and lastly rabbits and dogs ; poultry are only bitten exceptionally.

3. Man is protected by animals. The more easily the anopheles are able to satisfy their need of blood on livestock the more that protection is complete. The presence or absence of anopheles in houses is regulated in this manner.

[Abstract No. 1]

4. It is not so much the greater or less abundance of blood nourishment which regulates the relative density of the anopheles fauna as the extent and suitability of the places where their larvae develop.

It may, therefore, be concluded that in the countries of Europe where mosquitoes are not too numerous, domestic animals play an antimalarial role of the first order, by attracting to them the great majority of the anopheles. Far from exercising, as might be supposed, a prejudicial action by contributing to the maintenance of the anopheles of a locality, they divert and separate dangerous relations which, in their absence, would certainly be established between these anopheles and man (1).

It is in this way also that the progress of agriculture improves hygiene in pastoral countries. It seems that antimalarial prophylaxis may derive real benefit from these recorded facts.

2 - **Scientific Food Problems in France during the War.** — *Comptes des rendus Séances de la Commission d'Alimentation de la Société de Biologie*, pp. 160, Paris, 1919.

The « Comptes rendus des Séances de la Commission d'Alimentation de la Société de Biologie » from the May 25, 1918 to the March, 1919, meetings held under the presidency of Prof. Charles RICHET, summarised by M. R. LEGENDRE, Secretary of the Commission, are collected in one volume.

Numerous questions have been dealt with in the course of these meetings, particularly by the inter-allied scientific Food Commission at Rome. Among others, have been dealt with the questions of flours, their degree of bolting and their preparation for making war bread, of food supplies, of the requirements of the body for fats (the experimental data are insufficient to establish the need of a minimum of fats; it appears, however, that the ration should contain a certain amount of fat but the quantity cannot be fixed; fats of vegetable origin are as digestible as animal fats; there is reason to recommend their use which is economically less costly), of milk, of cattle, of requirements in nitrogenous matter, etc. The report of the inter-allied scientific Commission relating to the influence of anthropometric and climatic factors on the food requirements of the Allies, prepared by Prof. E. H. STARLING, is also given.

The volume reviewed includes a second part (pp. 65-159) which is an analytical bibliography of French works published during the war (1914-1918) on food questions and alimentary hygiene. Some of these works have already been dealt with in this *Review* (2).

3 - **Influence of High Temperatures and Dilute Alkalis on the Antineuritic Properties of Foods.** — DANIELS, A. L., and MCCLURG, N. I. in *The Journl of Biological Chemistry*, Vol. XXXVII, No. 1, pp. 201-213, 5 diagr. Baltimore, Jan., 1919.

The authors have studied the effect, on the antineuritic properties of

(1) All animals bitten by anopheles are absolutely resistant to malaria, consequently the mosquito which bites them cannot draw from their blood the organism of malaria and transmit it to man. (*Ed.*)

(2) These questions were dealt with in the *Review* in the course of their development. See *R.* Nov. 1917, No. 1700; Jan. 1918, No. 3; Feb. 1918, No. 216; March 1918, No 343 and 344; April 1918, No. 379. See also *R.* July-Sept. 1919, No. 812. (*Ed.*)

cabbage, soya beans and haricot beans, of cooking: (1) in boiling spring water; (2) in boiling water to which a small quantity of bicarbonate of soda was added; (3) in an autoclave at 120° C. fo 115 minutes. Admitting that the water-soluble vitamine is more liable to be decomposed by external agents than substances not soluble in hot water, the food value of substances extracted by water used in cooking was tested on young rats; these substances were fed abundantly in rations otherwise complete. The growth curves obtained indicate that there was in no case appreciable destruction of the water-soluble vitamine.

The results obtained by the authors for the water-soluble vitamine treated with dilute alkali do not agree with the results obtained by McCollum and Simmonds (*Journal of Biological Chemistry*, Vol. XXXIII, No. 1, p. 55, 1918). These two writers had reported cessation of growth in rats fed with vitamine soluble in water, to which alkali was added, boiled for one hour. It is, however, probable that their rations contained a very small quantity of antineuritic vitamine, derived from 10 % of wheat embryo, while the rations used by the authors contained a much larger amount of vitamine; this explains why the slight destruction indicated by failure to grow in the experiments of McCollum and Simmonds did not appear in the experiments carried out by the authors.

The results obtained by heating foods to 120° C. do not agree with those reported by Chick and Hume (*Proceedings of the Royal Society*, Series B, Vol. XL, p. 60, 1917-1918) according to which the use of large amounts of preserved foods may cause serious danger.

The authors think that this conclusion is unfounded at least from the standpoint of the antineuritic vitamine content of the foods. In agreement on this point with McCollum and his co-workers, they think it is improbable that, during the commercial preparation of tinned foods, the vitamine can be destroyed to such an extent as to be deficient in the ration where the usual amount of tinned food is eaten.

4 – **Action of Ultra-Violets Rays on Vitamines** (1). — Zilva, S. S., in *Biochemical Journal*, Vol. XIII, No. 2, pp. 164-171. Cambridge, July, 1919.

The fat-soluble A factor in butter fat is destroyed by an 8 hours' exposure to ultra-violet rays; at the same time the butter is bleached and becomes unfit for consumption. The author therefore asks whether the sterilisation ofmilk by the ultra-violet rays can decrease its nutritive value?

The antineuritic and antiscorbutic vitamines are not destroyed by ultra-violet rays; in fact, the author has reported that the exposure of neutralised lemon juice for 8 hours to ultra-violet rays did not influence its antiscorbutic activity, and that a similar exposure of autolysed yeast juice did not impair its antineuritic power.

5 – **Hygienic and Food Value of Carrots and Tomatoes.** — I. Sugiura, K. A., Preliminary report on the preparation of antipolyneuritic substances from carrots and yeast, in *The Journal of Biological Chemistry*, Vol. XXXVI, No. 1, pp. 191-196. Baltimore, Oct., 1918. — II. Denton, M. C. and Kohman, E., Feeding experiments with raw

(1) See *R.*, July-Sept., 1919, No. 1000. (*Ed.*)

and boiled carrots, *Ibidem*, Vol. XXVI, No. 2, pp. 249-263, 2 diagr., Nov., 1918. — III. GIVENS, M. H. and MCCLUGAGE, H. B., The antiscorbutic property of vegetables, an experimental study of raw and dried tomatoes, in *The Journal of Biological Chemistry*, Vol. XXXVII, No. 2, pp. 253-269, 6 diagr. Baltimore, Feb., 1919.

I. — PREPARATION OF ANTIPOLYNEURITIC SUBSTANCES FROM CARROTS AND YEAST (1). — Natural curative substances for the treatment of polyneuritis induced in pigeons and other fowls by a diet of polished rice have been prepared from residues of rice polishing, autolysed yeast, animal tissues, cabbage, and potato juices, and the yolk of egg. During the last 10 years many scientists have endeavoured to isolate these curative substances so as to establish their chemical nature. During the last 3 years artificial antipolyneuritic substances have been prepared and discussed by FUNK, WILLIAMS, WILLIAMS & SEIDELL, but VOEGTLIN & WHITE, STEENBOCK and HARDEN & ZILVA have not confirmed their results. In a preceding paper (*Journal of Biological Chemistry*, Vol. XXXVI, p. 171, 1918), the author has shown that both water and alcoholic extracts of fresh carrots contain growth-promoting substances. Further, he noted that his yeast preparations had the power of growth-promoting equally with the carrot extracts.

By means of experiments described in the paper reviewed, the author has proved that extracts of fresh carrots and crystalline substances extracted from yeast preparations (brewers' yeast filtered, pressed, dried in the air and ground; the powder so obtained was suspended in water and dialysed; the crystals form on the outer wall of the dialysing membrane) can cure polyneuritis in pigeons, in those cases in which the disease has developed rapidly, namely, in about 20 days; but they did not prevent death in cases in which the symptoms developed slowly, and in which the birds had not only lost the power of muscular movement, but were also emaciated.

I. — ALIMENTARY VALUE OF RAW AND COOKED CARROTS. — This has been ascertained by means of experiments on white rats. The results were as follows: —

Ordinary methods of cooking do not perceptibly diminish the nutritive value of carrots, at least when they form part of a mixed diet. But a considerable portion of the calorie value of the food is lost if the water used in cooking is rejected (2), as, indeed, is generally the case with food consumed by animals when the water used in cooking is not added.

Carrots, with a suitable supplement of starch, purified commercial casein, butter or lard, and salt, so that 50 % of the calories are still derived from the carrots, will produce normal growth and reproduction in white rats.

Carrots as an exclusive diet, except for the addition of calcium, phosphorus, sodium, and chlorine, can maintain animals in good health, as far as can be judged from their appearance, for as long as 16 weeks. Although there is no growth, the animals on this diet maintain their live weight and sometimes even increase it. Owing to the great variation in the nutritive

(1) See *R.*, Feb. 1918, No. 125.

(2) See *R.*, May 1919, No. 554. (*Ed.*)

value of carrots and in the vitality of different animals, the results of this diet are somewhat inconstant.

Carrots contain considerable quantities of water-soluble and fat-soluble vitamine.

When, in a carrot diet, the proportion of nitrogen was diminished by the addition of some non-nitrogenous food, such as fat or starch, a great number of the rats were attacked by dropsy (1).

III. Antiscorbutic properties of raw and dried tomatoes (2). — Holst and Frölich (*Zeitschrift für Hygiene*, Vol LXXII, p. 1, 1912; Vol. LXXV, p. 334, 1913) and Chick & Hume (*Transactions of the Society of Tropical Medicine and Hygiene*, Vol. X, p. 141) found that dried vegetables were more or less deficient in the antiscorbutic property. Chick, Hume and Skelton (*Biochemical Journal*, Vol. XII, p. 131, 1918) have recently reported that the feeble antiscorbutic property of fresh milk is destroyed by drying or by being kept for a long time after drying. Hess and Hunger (*Journal of Biological Chemistry*, Vol. XXXV, pp. 479-487, 1918) have stated that dried vegetables have little or no antiscorbutic virtue. Stefánsson (*Journal of American Medical Association*, Vol. LXXI, p. 1715, 1918), alleges that the strongest antiscorbutic qualities reside in certain fresh foods and diminish or disappear with storage by any of the common methods of preservation, i. e., in tins, with vinegar, with oil — etc., drying etc. Givens and Cohen (*Journal of Biological Chemistry*, Vol. XXXVI, p. 127, 1918), experimenting with the influence of temperature on the vitamine in the drying of cabbage have concluded that the degree of temperature during that operation is the factor which determines the presence or absence of the accessory antiscorbutic substance.

The authors have experimented with the influence of temperature on the antiscorbutic properties of the tomato and have drawn the following conclusions : —

Fresh tomato is an efficient antiscorbutic agent. A small daily addition of raw tomato (1 gm.) to a diet known to cause scurvy in guinea pigs, preserved these animals in a perfect state of health, as far as could be judged.

Raw tomatoes dried in a blast of air either at a low temperature (35°-40° C.) or a high temperature (55°-60° C.) retain a noticeable amount of their antiscorbutic potency. It is possible that the drying at either temperature may destroy some of the antiscorbutic vitamine, but to what degree has not yet been ascertained. These experiments confirm the results of Chick, Hume, and Skelton, who believe that scurvy is due to the deficiency, in the diet, of a specific accessory substance, and they corroborate

(1) The Committee for the control of foodstuffs attached to the office of the Food Controller in the United Kingdom drew the attention of the public, during the war, to the high food value of carrots : it pointed out that 3 lb. of carrots were equivalent to 2 lb. of potatoes — 1 lb. of veal or chicken — lb. of bread — 6 lb. of tomatoes — 7 or 8 eggs. — *Bollettino dei consumi, pubblicazione del Ministero degli Approvvigionamenti e dei Consumi alimentari*, No. 56-57, p. 15. Rome, Apr. 21-28, 1918.

(2) See *R.*, Dec., 1918, No. 1322. (*Ed.*)

the contention of COHEN and MENDEL that roughage, in as much as it affects the structure of the diet, is not the determining factor.

6 – **Destruction of Bed Bugs (*Cimex lectularius* Mor.) by Chloropicrin.** — BERTRAND, G., BROCQ-ROUSSEV and DASSONVILLE, in *Comptes rendus de l'Académie des Sciences*, Vol. CLXIX, No. 9, pp. 441-443. Paris, Sept 1, 1919.

The problem of the destruction of bugs is of very great importance because of the present necessity of disinfecting military barracks and numerous civil buildings.

The authors have experimented with chloropicrin and their trials have enabled them to determine that the destruction of bugs can be effected with such small doses of that substance that its use is practical. Doses of 4 to 10 grammes per cubic metre appear to be most suitable (the bugs are then killed in from 1-2 ½ hours). In case the eggs are not destroyed, the hatching period being about 8 days, a fresh disinfection should be made about 2 weeks after the first to insure the destruction of the new generations.

The powdering of the chloropicrin in the premises and entry into them is facilitated by the use of one of the anti-gas masks used during the war, such as the A. R. S. mask.

RICULTURAL IOWS AND ONGRESSES

7 – **The Fair of Hanoi.** — *Bulletin économique de l'Indochine*, New Ser., Year XXII, No. 136, pp 289-364, 6 phot. Hanoï-Haïphong, May-June, 1919.

A detailed report of Hanoï Fair in 1918 which, after the example of the celebrated fairs at Nijni-Novgorod, Leipzig, Lyons, Bordeaux, etc. was instituted with the object of making known the products of the countriy (in this case of the whole of Indo-China), to take stock, to a certain extent, of its wealth, the schedule of its productive faculties, in order to be able with certainty to induce supply and satisfy demand, to develop the production of the colony, the expansion of French industry and commerce.

But the Hanoï fair could not rival a sample fair at Lyons (because of its still rudimentary industry and of the commercial mentality of the natives, etc.) and it was a real market of Indo-China. In the eyes of the committee of the fair, if imports were interesting, exports had a considerable importance for the future of the Colony, and this fair was like the basis of a catalogue (the original article contains the complete list of the exhibitors and of the products exhibited) of local wealth, like a detailed memorandum of all that Indo-China could furnish and manufacture. The success of this exhibition has surpassed all expectations.

CROPS AND CULTIVATION

ICULTURAL TEOROLOGY

8 – **The Importance of Agricultural Meteorology in Tropical Countries.** — MC LEAN, F. T., in *The Philippine Agriculturist*, Vol. VII, No. 7, pp. 191-194. Los Baños, Feb., 1919.

It is not only in temperate regions that agricultural meteorology attracts increasingly the attention of farmers, they are also interested in it in tropical countries, where the dominating influence of the position of

the sun and its effect on wind, cloud and rainfall make changes in weather much more regular and facilitates considerably the adaptation of cultivation to the climate. Thus, for example, in the Philippine islands the periods of sunshine and the amount of rainfall are in close connection with the north-east trade wind which blows steadily from November to April and the south west monsoon between May and September. Local topographical conditions (proximity of large stretches of water and high mountain ranges) influence the effects of the winds in a constant and well defined manner, and enable the frequency and distribution of meteorological phenomena to be calculated with satisfactory approximation. Even typhoons, apparently so erratic, have periods of greater or less frequency annually and the precise determination of these periods would be useful to rubber planters, enabling them to arrange the different operations and to choose the most favourable seasons for carrying them out.

Plants which grow in the tropics at constantly high temperatures are very sensitive to even slight changes of temperatures. At Los Baños, the mean annual temperature is 1° C. lower than at Manila and this slight difference is sufficient to give these two places a somewhat different agricultural geographical situation.

The intense insolation in the tropics influences the processes of assimilation (photosynthetic) by restricting them in a remarkable manner. Numerous plants cultivated in tropical regions require to be protected by the shade of more resistant trees. The coconut palm, even, which grows on the equator, feels the effect of sunshine which, from 10 a. m. to 2 p. m., reduces the photosynthetic processes by almost one half, as has been shown by experiments carried out at the Agricultural College of Los Baños during the summer of 1918. One of the phenomena which has the strongest influence on the life and growth of plants is certainly evaporation. In the Philippines, evaporation, owing to the strong light and high temperature, is naturally intense and rapid, so much so that a month with a smaller rainfall than 50 mm. should be considered dry, while in temperate regions a monthly rainfall of 50 mm. assures the growth of any plant. The requirements of different crops as regards the various meteorological factors and their sensitiveness to different unfavourable meteorological phenomena vary from one crop to another and also for a single plant in the phases of growth. An exact knowledge of the distribution and the frequency of meteorological phenomena in a locality cannot but facilitate the experiments undertaken by the farmer to eliminate or at least to reduce the negative effect of climate. In the Philippine islands the extreme range is from a mean annual temperature of 26.8° C. at Manila to 17.8° C. at Baguio. In the latter locality the rainfall is 4000 mm. in nine months, while in north-eastern Luzon the rainy season is reduced to 6 months and the total rainfall to 2800 — 3500 mm. The climatic conditions are therefore very different: from an absolutely tropical temperature one changes to sufficiently temperate conditions for the introduction and growth of European plants (for example, peas in the valley of Mariquina). It is, therefore, more essential in the Philippines than in other places to undertake a careful

meteorological examination when it is intended to start a farm and to make a choice of different crops.

9 - **Effect of Climate on the Growth of Wheat in Portugal.** — Da Silva Fialho João, in *Boletim da Associação Central da Agricultura Portuguesa*, Year XX, Vol. XX, pp. 288-294. Lisbon, Sept., 1918.

In Portugal in general, and especially in the southern provinces, the distribution of temperature and moisture does not always correspond with the requirements of the growth of wheat which, each year, suffers more or less from unfavourable meteorological factors. Among these the most important are moisture, temperature and light.

Moisture. — According to the author, in order to obtain 10 hectolitres of grain per hectare, a good harvest for the district of Beja, the plants should have at their disposition 290,000 kg. of water. The average annual rainfall in the region in question is about 550 mm. corresponding on each hectare to a total mass of 5,500 000 kg. of water, and even admitting that only a third of this water filters and penetrates into the soil, a sufficient quantity always remains.

The table noted below contains data relating to the rainfall collected at the Franzini Meteorological Observatory at Beja during the period 1905-1911

Monthly and annual rainfall in mm. at Béja from 1905 *to* 1911.

	1905	1906	1907	1908	1909	1910	1911
January	155.6	34.6	68.8	83.1	58.0	13.7	18.3
February	2.6	36.0	26.3	1.1	22.7	23.9	29.6
March	25.5	61.0	1.4	45.1	111.8	31.3	98.1
April	40.2	5.0	40.1	34.6	19.8	40.5	70.4
May	12.1	102.6	116.7	20.8	68.9	94.1	28.6
June	51.3	49.9	0.0	59.5	10.5	9.3	26.2
July	3.2	23.2	0.5	0.2	0.2	0.0	1.5
August	0.8	0.0	0.0	0.4	3.0	0.1	34.3
September	27.2	56.7	73.2	5.3	19.3	6.1	1.2
October	95.7	47.6	145.5	30.7	22.2	67.8	94.4
November	131.4	64.8	163.4	149.4	126.6	38.8	81.4
December	66.8	12.8	75.6	83.0	123.9	209.9	3.3
Annual rainfall.	**502.4**	**494.2**	**711.5**	**523.2**	**569.9**	**535.4**	**539.4**

The total quantity of rain would therefore be sufficient, even in this locality, which is one of the driest, to assure a good harvest of wheat. But in Portugal, what hinders the growth of wheat is the bad distribution of rainfall, and the absence of rain during the critical period, when the plants have most need of it.

It should be noted : — (1) that transpiration varies with the different phases of the vegetative period ; it is slight during the first phases, increases

so as to reach the maximum a little before flowering (at the time of forming the ear), then decreases so as to become nil in the very last stages of complete ripening; (2) that evaporation increases with the elevation of the temperature and exposure to the sun; (3) that it diminishes when the water contains salts in solution (nitrate of soda, chloride of potassium, etc.); (4) that the transpiration of the plant and the evaporation of the soil take place almost at the same time, that is to say when the rainfall is generally less abundant.

If, during the critical period, the reserve of water in the ground is not sufficient to supply the requirements of evaporation and transpiration, the harvest will be seriously affected both in quality and quantity.

It is therefore advised: — (1) To work the ground deeply to increase the reserve of water; (2) to crumble the topmost layer of the soil (dry farming), in order to protect the soil against evaporation, by a very finely powdered top layer; (3) to apply nitrogenous manures to diminish transpiration.

In conclusion, it can be said that the success of wheat growing in Portugal depends less on the total quantity of the rainfall than on the distribution, of the rainfall which is generally scarce at the critical period, and for this reason it is necessary to have recourse to all methods by which the reserve of water can be increased and evaporation diminished.

Temperature. — To spring up, develop, tiller, flower, form and ripen its grain, wheat requires a grand total of daily temperatures of from 2000° to 2400° C. These data are confirmed by the observations made at the agronomic Station of the 7th. Agricultural Circle (Santarem), on 3 kinds of local wheat, Durázio molar, Amarelo barba preta and Ribeiro, and are recorded below.

	Durázio molar	Amarelo barba preta	Ribeiro
From sowing to springing up	160°	160°	125°
From springing up to flowering	1 260°	1 260°	970°
From flowering to harvest	960°	960°	930°
Total of the temperatures.	2 380°	2 380°	2 025°

After these observations, applicable to all regions, and which give a more or less exact a idea of the requirements of wheat as regards temperature, the author studies the special conditions which exist in Portugal. Sowing is carried out at two different times of the year, autumn sowing, immediately after the first autumn rains, and spring sowing, as soon as the severity of the winter has passed. In both cases germination takes place at a low temperature, and is then hindered by subsequent cold which, when it is accompanied by excessive moisture in the soil, which frequently happens in Portugal, may destroy the seeds almost entirely.

Wheat can also be damaged by drought during dry winters, which causes feeble tillering, or by too rapid rise of temperature in the spring which, particularly if this rise is accompanied by lack of moisture, causes too early growth and the formation of ears shorter than usual. Scorching is not infrequent ; it causes a decreased yield and a deterioration in the quality of the grain.

Light. — As regards light, wheat always finds in Portugal conditions very favourable to its development, However, the beneficial action of light without the help of moisture and temperature is not alone sufficent to assure a good and abundant harvest.

10 – **Effect of Weather Conditions on the Setting of Fruit in the Plum in Minnesota, U. S. A.** — Dorsey, M. J., in *Journal of Agricultural Research*, Vol XVII, No. 3, pp. 103-126, 1 fig., 13 pl. Washington, June, 1919.

Results of a series of parallel meteorological and biological observations made with the object of determining in what manner and to what extent, weather influences the setting of fruit in the plum.

The author made these observations at the Fruit Breeding Section of the Agricultural Experiment Station of the University of Minnesota, on different species of *Prunus*, during the period 1915-1917. The most important weather conditions which affect the setting of fruit are certainly rain and low temperature, which act in a clearly negative manner and may cause a failure of the crop even when the trees have flowered abundantly.

However, to understand correctly how rainfall and temperature affect the setting of fruit, it is necessary to investigate this phenomenon briefly from an anatomic and physiological point of view.

The period during which the stigma of the plum remains receptive is, at most, one week ; pollination must therefore be effected during this relatively short period to enable fertilisation to take place. All conditions which delay pollination cannot therefore but have a negative influence on the formation of fruit. Further, besides the degree of receptivity of the stigma, there is another phenomenon which helps to still further limit the time during which fertilisation is practicable ; this is the detaching of a part of the pistil which takes place from 8 to 15 days after flowering. And, before the actual abscission of the style is effected, the layer or diaphragm of the modified and thickened cells of the abscis layer constitutes an obstacle to the lengthening of the pollen tube towards the ovary. All phenomena which hinder or slow down the growth of the pollen tube can therefore also influence the setting of fruit in a negative sense.

Now, continuous rain at the flowering season hinders pollination considerably and if prolonged may absolutely prevent it.

In an atmosphere saturated with humidity, the anthers, even if ripe cannot open, and if they are already open, they bend over at once when it commences to rain. Rain weather during the period when the stigmas are receptive is itself sufficient to prevent the setting of fruit. Similar results have been obtained artificially by continuous spraying of trees in flower with water.

The growth of the pollen-tube is in close relation with the temperature. The time required for penetration of the whole length of the style at a temperature of 55° to 60° F. (12.80 to 18.30 C.) is about 6 days for the variety " Surprise ,, . The rate of growth of the pollen-tube decreases proportionally with the lowering of the temperature and, according to Goff, at 40° (4° F. C.) pollen ceases to germinate.

On the other hand low temperature does not appear to exercise any influence on the date of abscission of the style ; however, it is easily understood that a cold spring at the time of flowering may hinder the setting of fruit by retarding the growth of the pollen-tube up to the moment when the layer of disintegrated cells on the plane of abscission prevents the pollen-tube from growing towards the ovary.

In 1915, 1916 and 1917, there were very light crops of plums at the fruit breeding Station.

In 1915, at the time of flowering and fruit setting the weather was characterised by frequent rain and by low temperature for a week ; consequently the conditions were unfavourable to pollination and to the growth of the pollen-tube.

In 1916, flowering was late and was accompanied, on the one hand, by high temperature favourable to the growth of pollen-tubes, while, on the other hand, there were, especially during the period when the stigma was receptive, rain and wind unfavourable to the emission and dissemination of the pollen.

Lastly, in 1917, rain, wind and low temperature hindered the setting of fruit and caused a very light crop.

In 1912, 1913 and 1918, when the percentage of fruit set was rather high, there was little rain during the flowering and fertilisation periods, and the temperature was, generally, high. In 1914, a year with a very high percentage of fruit set and an abundant crop, there was a high temperature and an absence of heavy rain. The two weather factors which dominate the fruit production of the plum in Minnesota are, then, rain and low temperature, and their negative influence is made particularly striking by the short time during which the stigma is receptive and by the rapid formation of a partition which leads to the detachment of a large part of the style.

11 – **Resistance of Flower Buds and Flowers of the Apricot to Low Temperatures in New Mexico, United States.** — Cleve Hallenbeck, in *Monthly Weather Review*, Vol. XLVII, No. 4 p. 24. Washington, April, 1919.

It had previously been observed that, in the semi-arid regions and on the high tablelands in the west of the United States, fruit buds of fruit trees and generally the tender parts of plants are resistant to falls in temperature, and that in the plains or moister districts of the east such falls in temperature kill them. The cause of the phenomenon is not yet known; moisture, the conditions of the soil, altitude, and other factors still unknown may contribute to it and in different degrees. At any rate, air and soil seem to reduce the effect of low temperatures.

The data given below show a notable instance of resistance of the apri-

cot tree (in the valley of Pecos) to very low temperatures, especially afte a period of relatively low humidity, in March, 1918.

Date	Minimum temperatures	State of growth
March 1	− 0.56° C	The tip of the bud is pink.
» 2	− 2.22°	—
» 3	− 2.78°	Buds open.
» 4	− 1.67°	—
» 5	− 7.22°	30 % of the buds have opened.
» 6	− 2.78°	—
» 7	− 1.11°	50 % of the buds have opened.
» 8	− 1.67°	—
» 9	− 2.78°	—
» 10	− 2.22°	—
» 11	− 7.78°	In full flower.
» 12	− 1.11°	—
» 15	− 2.78°	Flowers begin to fall.
» 16	+ 1.11°	—
» 18	− 2.78°	—
» 19	− 1.67°	—
» 23	—	Fruit sets.

On March 25, an inspection of the trees at various heights showed that the percentage of dead and damaged fruits scarcely reached 7 %, while 93 % of the flowers had set fruit regularly. Besides, it is thought that in the 7 % are included flowers which did not set fruit and fruit which fell for reasons unconnected with the cold. In the case in question, it may be said that the exceptional cold which prevailed throughout the period between the commencement of flowering and the end of setting fruit caused practically no damage to the trees.

OIL PHYSICS, CHEMISTRY AND ICROBIOLOGY

12 - **American Papers on Soil Science Read at the Philadelphia Meeting of the American Chemical Society.** — *Science*, N. S., Vol. L, No. 1296, pp. 421-424. Lancaster, Pa., Oct. 31, 1919.

Groups of papers read at the meeting of the American Chemical Society at Philadelphia in September, 1919.

Robinson, W. O., Gardiner, R. F., and Holmes, R. S., *The water-soluble manganese of soils.* — Results obtained by frequently shaking 24 samples of soil with distilled water for 8 days. The following deductions were arrived at : —

(*a*) 1 to 10 % of the total manganese of soils is soluble in water.

(*b*) Carbon dioxide greatly increases the solubility of the manganese.

(*c*) Surface soils contain much more soluble manganese than subsoils, and this difference is greater the finer the texture of the soil.

(*d*). The amount of oxides of manganese in soil extracts varies from 0-24 parts per million ; it is large enough to affect the bacteriological flora and probably has also a more direct influence on plant growth.

ROBINSON, W. O., *Composition of "ultra clay" from certain soils.* — The author calls "ultra clay" that part of the soil which remains in nearly permanent suspension when it is treated with pure water: it has no organised structure and behaves like any colloid. It is essentially a finely divided hydrous aluminium silicate, with some of the aluminium replaced by iron; it contains also hydrated oxides of aluminium, iron, titanium, silicon, and probably of manganese. On the other hand, the proportion of phosphoric acid and of potash is higher in "ultra clay" than in the soils from which they were derived. Organic matter is always present and probably plays an important part in deflocculating the matter in suspension.

ANDERSON, M. S. AND FRY, W. H., *Composition of soil extracts.* — The salts deposited on the evaporation of the water extracts of soils are much morecomplex than is indicated by a statement of the ions found in the solutions of the extract. There is a marked general similarity between the salts obtained on evaporation of water extracts of soils and those obtained by both natural and artificial evaporation of sea water.

That does not, however, mean to indicate that saline deposits so obtained contain all the salts of natural saline deposits, because the latter represent crystallisation from a composite extract. We may suppose that, under ordinary soil conditions, the above-mentioned complex salts are probably always in solution in the soil moisture itself.

13 – **On the Agricultural Properties of Soils; Research on the Reaction of Soils.** — RABATE, E. (Director of the Agricultural Department of Cher), note by M. SCHRIBAUX, in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. V, No. 35, pp. 846-848 and 854-858. Paris, Oct. 29, 1919.

In order to judge the agricultural properties of soils and water and especially their chemical and physiological properties, among other tests, it is indispensable to know whether they have an alkaline or an acid reaction. To quote only a few established facts; — Acid waters are bad for irrigation; in acid soils advantageous and immediate results may be expected with calcarious fertilisers (marl, lime, composts) and with alkaline manures (dung, liquid manure, slag, ashes). These almost always require phosphatic manures, and natural phosphates, finely ground, give good results. But bulletins of soil analyses issued by agricultural stations are usually silent on the subject of the reaction of soils.

The author describes a new method which he has tested in various geological formations. He proposes to have recourse to logwood dye. This colouring matter has been studied by CHEVREUL, who extracted haematoxylin from it. The wood decoction turns yellow with dilute acids and red with concentrated acids; it is decolourised by suphuretted hydrogen and turns violet with alkalis and alkaline salts; lime gives a blue precipitate.

The method of working is as follows: — 20 cc. of distilled water or rain water is poured into a clear glass tube and 20 drops of the reagent are added; 5 gm. of fine earth, dried and sifted, are then mixed in the solution and left for 15-20 minutes.

Alkaline soils colour the water mauve or violet even when the alkalinity is very slight; calcareous soils that lead to chlorosis give a more

intense reaction. With acid soils the water becomes pale yellow, loses colour, or becomes leaden tinted. Neutral soils do not alter the original colour ; they are very rare.

This is a simple and rapid method which, according to the author, is extremely sensitive.

14 – **Formation of Soluble Matters in Virgin and Cultivated Soils estimated by means of Lowering the Freezing Point.** — Millar C. E. (Michigan Agricultural Experiment Station), in *Soil Science* Vol V. VII, No. 4, pp. 253-257, 2 fig., bibliography of 3 works. Baltimore, 1919.

The whole of the soluble matter in 6 sandy clay and sandy soils, both virgin and cultivated, were separated by washing ; the portions of soils so separated were incubated, and every 40 days their contents in soluble matter formed were determined by means of the lowering of the freezing point (1).

It was found that, in 3 cases, there was a greater production of soluble matter in virgin than in cultivated soils, and the total concentration of the respective solution was also higher. In the other cases, there were only slight differences between the virgin and the cultivated soils. However this may be, the author is led to believe that among the changes caused in soils by cultivation when a sufficent quantity of fertiliser is not restored to them, there is a marked decrease in the rate of formation of soluble matters. To ascertain whether this formation of soluble matter is due to biological or to physico-chemical actions is a problem of great interest, which is being studied along with other problems at the Agricultural Experiment Station of Michigan.

15 – **Toxicity of Alkaline Salts in the Soil.** — Sirgh, T. M. (Oregon Agricultural College), in *Soil Science*, Vol. VI, No. 6, pp. 463-477, bibliography of 19 works. Baltimore, 1918.

The detrimental effect of the accumulation of alkaline salts in the soil has formed the object of study and is well known, but up to the present experimental investigations have only been made on isolated salts or on arbitrary mixtures of those salts.

The author has endeavoured only to study the phenomenon under Oregon conditions and he divided his work into 3 parts : --

(*a*) Determination of the toxic points of chloride, nitrate, carbonate and sulphate of sodium on peas and wheat.

(*b*) Determination of the toxic point for peas and wheat by using a mixture of salts similar to those found on analysing field soil.

(*c*) Determination of the effect of chloride, nitrate, carbonate and sulphate of sodium upon ammonification, nitrification, and nitrogen fixation.

The observations were made on a heavy loam soil, highly productive under normal conditions and under suitable cultivation, but on which, under dry farming. alkaline spots gradually appear, whilst under irrigation, perhaps excessive, the alkali soon appears.

(1) See *R.*, Feb. 1919, No. 154. (*Ed.*)

The salts experimented with are classified as follows in decreasing order of toxicity :— Chloride, nitrate, carbonate and sulphate of sodium both as regards the germination and the growth of wheat and peas and relatively to the ammonifying, nitrifiying and nitrogen-fixing bacteria, the determining factor of this toxic action being found in the percentage of the anion and not of the cation. Small quantities of the different salts used had a stimulating effect both on the growth of the plant and on bacterial activity ; the degree in which this stimulating effect was noticed varied with the plant grown.

The toxicity point, that is to say the degree of concentration at which the detrimental effect is produced, for mixtures of salts in conditions similar to those in fields, agreed closely with that noted for each individual salt ; the toxicity point of the mixture of salts depends, therefore, on the percentage of chloride, nitrate, carbonate and sulphate present and how they are combined ; however, sulphate of calcium tends to lower the toxicity of the chloride, carbonate and nitrate of sodium.

16 - **Chemical Research on Land treated in Different Ways in Denmark.** — KRISTENSEN R. K., in *Tidsskrift for Planteavl* (135 Beretning fra Statens Forsøgsvirksomhed i Plantekultur), Vol. XXVI, Part 2, pp. 335-351, 2 figs. Copenhagen, 1919.

When making experiments on fallow, between 1888 and 1914, at the State experimental station near Ceskov in compensated plots, several chemical tests of the land used in the experiments were made as regards the nitrogen and phosphoric acid contents, and loss by lining. There was thus the means of estimating the effect of different methods of cultivation, on the chemical composition of the soil.

The nitrogen, phosphoric acid and organic matter contents of the soil are closely connected with the method of cultivation, particularly with the manuring and nitrogen-fixing properties of leguminous plants. In fact, land enriched with manure contains 0.058 % of nitrogen, while unmanured land only contains 0.016%. Where lupins have been used as green manure, without other manuring, the nitrogen content reaches 0.062 %.

During the investigation it was attempted to estimate the degree of accuracy of the work undertaken and with this object samples of each plot were taken from 2 to 10 times, taking each sample from a different part of the plot. The mean error for each sample was from 2 to 3 % on the content of the substance determined ; the soil experimented on was uniform, fine and sandy.

17 - **Denitrification in the Presence of Organic Substances Difficult to Decompose.** — NOLTE, O. (Mitteilung aus der landwirtschaftlichen Versuchsstation Rostock), in *Centralblatt für Bakteriologie, etc.* Part II, Vol. II., Nos. 7-9, pp. 182-184. Jena, 1919.

Growing experiments with mustard, in pots containing poor sandy soil with which had been mixed the residue of extracted quinine bark containing lime. Having observed in the 1st series of experiments a sensible dificiency of nitrogen, a 2nd series was carried out in which nitrate of soda in solution was added and a great loss of nitrogen was noted. The author has, therefore, every reason to conclude that even much lignified

quinine bark can be used as a source of energy for denitrifying bacteria, and denitrification is more intense when the quantity of oxygen is smaller, as resulted from a 3rd series of experiments, compared with the 2nd, and in which a double quantity of water was given.

18 – **Effects of the Oxidisation of Sulphur and Nitrification on Potassium and other Soil Constituents.** — Ames, J. W. and Boltz, G. E. (Ohio Agricultural Experiment Station), in *Soil Science* Vol. VII, No. 3, pp. 183-195, bibliography of 11 works. Baltimore, 1919.

Research with a view to the study of the solvent effect on potassium and other soil constituents of oxidation of sulphur in the soil by micro-organisms or "sulfofication" (1), compared with similar effects caused by nitrification. With this object several mixtures of sandy clay soil with chalk, dried blood, potassium silicate, slag, sulphur, and felspar were maintained at a temperature of 30° C. for 19 weeks.

It appears from the observations made that the nitrification of dried and the oxidation of sulphur in the soil mixtures increased the water-soluble potassium, chiefly owing to the sulfofication due to the addition of sulphur. The liberation of potassium was due rather to salts formed by sulfofication or nitrification than to the direct action of acidity on insoluble potassium compounds.

Ammonium sulphate affected the solubility of potassium, independently of the nitrification of ammonia.

On the other hand, calcium naturally present in the soil in the form of silicate or in some other form, was readily attacked by the acidity resulting from nitrification or sulfofication; on the contrary, magnesium compounds were much more resistant to the action of these solvents. Large quantities of aluminium and manganese were converted into soluble forms in consequence of the oxidation of sulphur in the sandy clay soil experimented with, whilst small amounts were made soluble by this action in a basic clay soil.

Nitrification had no effect on aluminium and only a very slight effect on manganese. Finally, no indication was obtained that iron compounds were appreciably affected by nitrification or sulfofication.

AINAGE AND
RRIGATION

19 – **Relation of Soil Moisture to Orchard Irrigation.** — Fortier, S., in *The Monthly Bulletin of the State Commission of Horticulture*, Vol. VIII, No. 7 (*Proceedings of the Fifty-first Convention of Fruit Growers and Farmers, at Riverside, California, May 28-29, 1919*), pp. 361-367. Sacramento, Cal., July, 1919.

In considering the importance of soil moisture in orchard irrigation practice, especially in dry zones, we should remember that the greatest need of arid soils in general and of orchard soil in particular is an abundant water supply and a high percentage of organic matter. The water-holding capacity of these soils must next be determined in order to ascertain the quantity of water to apply at each irrigation and how often to irrigate.

The quantity of water drawn up in the soil by capillarity is comparatively small; it is only where a water table is found within a few feet of the

(1) See *R.*, Jan. 1919, No. 24. (*Ed.*)

surface or where there is a body of free water in immediate contact with the soil that capillarity in effective. Gravity acts not only on the free water but also on capillary water and draws it downwards unless a pan or other impermeable material stops it.

The expense of changing furrow irrigation to basin irrigation may be avoided by improving the texture of the soil by the addition of sufficient organic matter.

20 – **The Water Problem in Sicily.** — SALEMI PACE, G., in *L'Italia elettrica*, Vol I, No. 5, pp. 56-61; No. 6, pp. 19-21. Milan, May and June, 1919.

In Sicily there are no long rivers, and even no permanent rivers with a considerable flow of water, but important springs, already utilised by municipalities and for agriculture, are often met with, as well as fairly important waterfalls used by mills and various small industries.

According to the " Relazione sui corsi d'acqua della Sicilia " (Report on the watercourses of Sicily) by the engineer PERRONE, watercourses whose permanent flow is sufficient for hydraulic power would furnish :—

On the northern slopes : 1110 H. P. with ordinary flow and 630 H. P. with the lowest low-water mark.

On the southern slopes : 7745 H. P. with ordinary flow and 5474 H. P. with the lowest low-water mark.

On the eastern slopes: 21 400 H. P. with ordinary flow and 14 200 H. P. with the lowest low-water mark.

Altogether, there may be on the three slopes, in round numbers, 30 000 H. P. with ordinary flow and 20 000 H. P. with the lowest. These limits might be greatly extended, by regulating the torrential water courses, which rush down from the high vallies, and by utilising them in electrical power stations.

According to information collected by the author, there are actually in Sicily 35 577 hectares of irrigated land; the position which they occupy would permit of irrigating a further 111 000 hectares; it is a question of ascertaining whether the island has at its disposal the quantity of water necessary for this irrigation.

According to M. NICOLO TURRISI COLONNA, whose experiments have been made in clay loam soils, a total of 8658 cubic metres of water would be necessary, and according to M. INZENGA, whose experiments have been made on arid lands, of calcareous tufa, 147 000 cubic metres of water in all would be required to irrigate 1 ha., once a week, for 7 months of the year. The author estimates that the coefficient of 0.7 litre per ha. per second might be adopted as the average consumption of water for irrigation, that is to say that, to give weekly irrigation during an uninterrupted period of 7 months, as the soil of Sicily requires, at least 11 000 cubic metres of water per ha. would be required. This figure corresponds closely with the averge of those obtained by M. TURRISI COLONNA and by M. INZENGA.

The " Commissione Reale per gli studi e proposte relativi alle opere di irrigazione " (Royal Commission for study and proposals relating to irrigation works) has adopted the coefficient of 0.5 litres per second but, ac-

cording to the author, this coefficient is too low and should be increased to 0.7 litre. To irrigate a further 111 000 ha. it would therefore be necessary to have at disposal during 7 months, 11 000 cubic metres × 111 000 = 1 221 000 000 cubic metres of water.

Estimating the annual rainfall at a general average of 500 mm. for the whole island, we have a total quantity of 12 730 million cubic metres of which about $^{7}/_{10}$ represent water which evaporates, that which feeds the springs and that which is used by plants; while $^{3}/_{10}$ (say 3819 million cubic metres) run off on the surface of the ground, denuding the soil and devastating it, and end by flowing into the sea. It is precisely from this amount of water that the quantity required for irrigating the above mentioned 111 000 ha. must be taken. This could be done by constructing artificial lakes or dams to retain the water at the mouths of the vallies.

The author then describes the means proposed or proposable by which the water could be collected and utilised.

Filter galleries serve to intercept, upstream, the water which circulates in the alluvial deposits of the bed and brings them to the surface. But there is not always subterranean water to set free, in the ravines or rivers with large and deep beds; their existence depends indeed on 2 factors: — (1) The presence upstream of sufficiently abundant springs; (2) The permeability of the alluvium which forms the bed of the ravins when it is not very strong; for the work of the filter galleries is not to collect and distribute rainwater but to supply irrigation during the dry season, which is only possible when they hold the water from hidden springs.

Underground dams are useful in narrow and deep vallies cut in calcareous tufa at the bottom of which abundant springs rise, some visible, others, more numerous, underground, filtering through the banks.

Mecanical conduits, chiefly intended for the orange gardens and the different irrigated cultivations in the low vallies and in the coastal plains, are very numerous; however much deep flowing water and phreatic (1) water discharge visibly into the sea. Many projects have been made to capture these waters; they consist in the construction of *underground dams* in clay strata. To hold underground water, an ancient method is always employed in the province of Palermo which consists in the construction of underground canals by means of wells called " pozzi a ripiano "; at present the construction of similar works in the locality of Etna is being investicated.

21 – **Irrigation and Watering in Syria and Palestine.** — PARMENTIER, PAUL, in *Comptes rendus de l'Académie des Sciences*, Vol. 169, No. 8, pp. 391-393. Paris, Aug. 25, 1919.

After having pointed out how defective the system of irrigation and watering in Syria and Palestine is, the author suggests a new method which consists essentially in replacing the cisterns for watering trees and irrigation trenches, or the partial submersion of irrigated plots by hollow cy-

(1) " Phreatic ,, is a term coined by Hay (*14th. Rep., U. S. Geol. Surv.*, II, 16) to designate underground water that can or may be tapped. (*Ed.*)

linders, open at the ends and with small holes pierced at the side of one end at a height of about 10 cm. These cylinders, in cast-iron, in concrete or in earthenware, have a maximum capacity of 20 litres for plantations of trees and less for the kitchen-garden plants. The end provided with lateral holes is sunk in the ground. These cylinders are buried to a depth slightly above that of the rootlets along the spaces between the trees.

In this manner 80 litres of water, completely used by the plant, would replace satisfactorily for the same time the 600 litres at present used, a considerable economy of 520 litres per tree would result and, in addition, there would no longer be damp air under the trees, nor toughening of green vegetables.

22 – **The Influence of Farmyard Manure on Clover.** — Russell, E. J. (Director of the Rothamsted Experimental Station, Harpenden), in *The Journal of the Board of Agriculture*, Vol. XXVI, No. 2, pp. 124-130. London, 1919.

An enormous quantity of work has been carried out during the last 35 years in connection with the manuring of different plants, but, in spite of its great importance in the crop rotation clover has been omitted, perhaps because of its liability to " sickness ", which renders it unsuitable for a continuous series of experiments. The author carried out a series of field tests on this subject ; he compared the residual value of ordinary farmyard manure and of farmyard manure cake-fed cattle, of shoddy rape cake superphosphate bone meal basic slag, on clover following a wheat crop on land where clover had not been grown for over 14 years. The manures were applied 1, 2, 3, and 4 years before the clover.

None of the manures, except farmyard manure, had any appreciable effect on the clover ; applied 2, 3, and even 4 years beforehand it produced notable increases in the yield of clover. It had, further, a distinct effect on the wheat crop grown after the clover, the heaviest crop of the latter having been followed by a heavier wheat crop. In conclusion it should be noted that the action of the farmyard manure only affected the first cut, the yield of the second cut being approximately the same with farmyard manure as with the other manures.

To sum up, farmyard manure has an important residual effect on clover which should be taken into account in estimating its influence on the croprotation.

23 – **Use of Natural Phosphates in Rice-fields in Indo-China.** (1) — Bussy (Directeur du Laboratoire d'analyses de l'Institute scientifique de Saïgon), in *Bulletin agricole de l'Institute Scientifique de Saïgon*, Year I, No. 9, pp. 265-266. Saigon, Sept., 1919.

In Cochin-China the soils of the rice-fields are not all of the same kind. They can be classed in two categories : —

(1) Soils containing humus, which occupy the rich alluvial plains of the west, as well as the bottoms of the valleys of the streams and rivers, flow-

(1) On the subject of phosphatic manures in rice fields see : — Manurial experiments with " tetraphosphate " in Italy, in *R.*, Feb. 1917, No. 142. (*Ed.*)

ing from the eastern regions. These are heavy yielding rice-fields. They contain up to 10 % of organic matter in different stages of decomposition, and 0.2 to 0.3 % of nitrogen. Their richness in potassium is sometimes fairly good, but they nearly always lack phosphoric acid and lime.

(2) The soils occupying the slopes of the valleys in the eastern region. They are worked as rice-fields by retaining the water by means of terraces They are of a sandy clay nature, sometimes even entirely sandy, poor in all fertilising elements, and lacking humus. In these soils phosphates employed alone have no appreciable effect.

In the rice- fields of the first type natural phosphate (phosphoric acid in a tricalcic state, associated with carbonate of lime) possesses two distinct actions, both conducing to the same useful effect. The first is the action of carbonate of lime which, in promoting nitrification, renders the nitrogen in the organic matter assimilable, the second, that of phosphate of lime which, owing to carbonic acid dissolved in the soil, water enters slowly into solution. The phosphoric acid then combines in an insoluble state with the iron and aluminium in the soil ; it can then be attacked by alkaline carbonates, and especially by carbonate of ammonia, which is formed by contact of carbonate of lime with nitrogenous organic matter.

Parallel to these two reactions another may occur, due to the solvent action of free organic acids which exists in soils containing a strong proportion of humus.

What happens in the soils of the second type lacking organic matter and whose reserves in fertilising elements are slight, ?

The action of carbonate of lime, brought by the phosphate, would have a somewhat harmful effect in provoking too active nitrification, which would tend to diminish the already-too-slightreserve of nitrogen.

As in the rich rice-lands, tricalcium phosphate will be subjected to the action of the dissolved carbonic acid, and phosphate of iron and aluminium would be formed ; but there the reactions would stop for nitrogenous organic matter is wanting and cannot produce carbonate of ammonia.

The phosphoric acid remains then in the state of phosphate of iron and aluminium which the plant can scarcely use. This explains the inefficiency of natural phosphates, employed alone in sandy soils and those not containing humus. In these soils, to obtain a useful effect with this manure, it would be necessary first to render the phosphoric acid soluble. This would be effected to a certain extent by making composts of organic matter and phosphates.

The author recommends the following economic formula :— Mix peat and natural phosphate in the proportion of 1000 kg. of peat to 20 kg. of phosphate. The heap, exposed to the air for 1 year, should be turned over from time to time. The solubility of the phosphoric acid would be increased by adding to the mixture 5 to 10 kg. of sulphate of potash. This addition of potassic salt would give a complete manure.

This compost could be used in quantities varying from 15 to 30 tons per hectare. It is well to use only finely ground phosphates, as the fertilising action of a phosphate depends on its fineness.

24 - **Potash in Tunis and Morocco.** — I. Bourguignon, R. (Services chimiques de guerre), The extraction of bromine and potash in Tunis, in *Bulletin de la Société d'encouragement pour l'industrie nationale*, Year CXVIII, 1st. half-year, No. I, pp. 140-147. Paris, 1919. — II. Search for potash in Morocco. *Le phosphate et les engrais chimiques*, Year. XXVIII, No. 1292, p. 282. Paris, 1919.

I. — Before the war, bromine came from the " Kalisyndicat " of Stassfurt, which had gained possession of the European market, and from the American union of producers of bromine. In consequence of the necessity of assuring the manufacture of asphyxiating and lachrymatory gas containing bromine, the bromine industry was established in Tunis at the suggestion of the War Chemical Services.

The mission sent to Tunis to search for salt deposits and salt lakes, in Tunis, in December, 1915, chose Sebkha el Melah, a natural depression of 15 000 to 20 000 ha,. stretching along the coast of Tunis near Zarzis, and consisting of a dried-up salt lake, which, under the salt layer, contains mother liquor at 27°.3 B, with the following composition :—

Chloride of sodium	158 gm. per litre
Sulphate of magnesium	22 » » »
Chloride of magnesium	141 » » »
Chloride of potassium	13 » » »
Bromide of magnesium	224 » » »

The French department of war chemicals drew attention to the advantage of simultaneous extraction of the bromine and potash salts.

The extraction of potash from the mother liquor had been carried out by the department of public works in Tunis at the salt deposits of Mégrine, using the Urbain process, which consists in precipitating the potash by fluosilicic acid, obtained as a by-product of the superphosphate factory at El-Afrane. This process was too costly, and the manufacture was stopped.

In the salt deposit of Sfax, and at Zarzis, the Merle process with magnesium liquor was used; but it was also abandoned, for rational salt-making can yield a kind of artificial carnallite, more or less charged with choride of sodium and sulphate of magnesium ; this is sebkhaïnite which the mother liquor gives at 36° B, containing scarcely any choride of potassium, and preserving all the bromine. The composition of sebkhaïnite collected above 33° B does not differ much from the following :—

Chloride of potassium	19.5 %
Chloride of sodium	10
Chloride of magnesium	27.2
Sulphate of magnesium	9.3
Water and insoluble matter	34

By the end of February, 1919, the factory at El Henèche had thus manufactured, more than 2 500 tons of choride of potassium of from 35 to 95 % strength.

The factory at Aïn es Serah, constructed by order of the Tunis government, on the experience gained at El Hanèche, will be capable of producing 50 000 tons of sebkhaïnite, which can be converted into choride with 22-23, or 60, or 90 % of potash.

The bromine industry has served as an introduction to that of potash, and Tunis will be able, henceforth, to furnish an important tonnage of salts of potash in the Mediterranean region.

II. — From investigations made in Morocco, it was found that the Moroccan trias sometimes contains chloride of potash. Potassic salts are also found in the salt lands on the banks of Lake Zima, situated between Saffi and Marrakech.

The conclusion that competent persons, who have studied the question, have arrived at is that potassic salts would be difficult to work in triassic soil ; on the contrary, it would be relatively easy to extract them from the salt deposits of Lake Zima. Samples of salt earth from Lake Zima contain up to 2.95 % potash ; the waters of the lake contain an average of 75 gm. of potash per litre. The richness in potash of the waters of Lake Zima would therefore be much greater than that of Sebkha el Melah (Tunis).

Appreciable quantities of choride of potash have also been discovered at Guercif, Agourai, El Boroudj, Figuig, Taourirt, Martimprey du Kiss, Khemisset, Dar Ouled Zidouh, Rhala, Demnat, and Debdou. Prospecting licenses for salts of potash have been asked for at Souk-el-Orba de Tissa.

25 - **Fertilising Action of Sulphur on the Vine.** — See No. 60 of this *Review*.

26 - **The Compound Interest Law applied to Plant Growth.** — Blackman, V. H. (Imperial College of Science and Technology, London), in *Annals of Botany*, Vol. XXXIII, No. 131, pp. 353-360. London, July, 1919.

The author, referring to work he undertook in collaboration with F. Gregory at the Cheshunt Experimental Station on the growth of cucumbers and to work of earlier writers, especially of Noll and his pupils on the sunflower, hemp and tobacco, observes that the growth of annual plants, at any rate in their early stages, follows approximately the law of compound interest. As a matter of fact, the dry weight attained by a plant at the end of any determined period depends on : — (*a*) the weight of the seed at the start, which represents the initial capital with which the plant starts ; *b*) the average rate at which the plant makes use of the material already existing to produce new material, which represents the interest on the capital employed ; (*c*) the period of growth.

The simple equation which best expresses the growth relations of an annual plant is $W_1 = W_0 e^{rt}$, where W_1 represents the final dry weight of the plant, W_0 the initial weight, e the base of the natural logarithms, r the rate at which the material already present is used to form new material, t the length of time considered. The term r is an important physiological constant, for it is a measure of the efficiency of the plant in the production of new material, and the greater the return of the plant in proportion to the material used, the higher is r. The rate r may therefore be called *the index of the efficiency of production of dry material* or *efficiency index*, and it not only indicates the productive efficiency of the plant, but it is also the exponential term in the equation which expresses the growth of that plant. For example, in some sunflowers, the mean *efficiency index*, for the period

ending with the formation of the inflorescence, may reach 0.1763, or 17.63 %, per day.

The author suggests that in all experiments dealing with vegetative growth, such as water or pot cultures, the *efficiency index* should be calculated; in this way the relative productive capacity of different plants at different periods would be determined, as well as the effect on the index caused by external conditions. A slight difference in the efficiency index of two different plants (difference due to a slightly greater rate of assimilation or to a more economical distribution of material produced between the leaves and axis) may cause a notable difference in the final weight; in oats, for example, a 6 % increase in assimilation may cause, after 100 days, an increase of 30 % in the production of dry material. The data of earlier writers show that the *efficiency index* is higher during the early stages of growth and that it then decreases slightly in the sunflower, hemp, and tobacco: it falls sharply at the beginning of the reproductive period, that is to say when the inflorescence first appears. There is also evidence that annual plants may lose considerably in dry weight at the end of their period of growth.

27 - **Variations in the Respiration of Leaf Cells with Age.** — BÉZAGU, M., in *Comptes rendus de l'Académie des Sciences*, Vol. CLXIX, No. 16, pp. 701-702. Paris, Oct. 20, 1919.

The various physiologists who have dealt with this question have correlated the intensity of respiration to the carbonic acid gas set free during 1 hour by 1 gramme green weight. They have thus ascertained that the activity of respiration decreases with the growth of the leaf. The same would be the case with the relation $\frac{CO^2}{O^2}$, the study of which has been the object of a recent work by M. NICOLAS (1).

The author, in his researches, has tried to correlate the intensity of respiration not to the gramme-hour, a purely physical unit, but to a physiological and histological unit, the cell respiring during one hour. For this he has correlated the respiration to the organ-hour under the following preliminary hypotheses: —

(1) Two mature leaves of the same species whose surfaces are very equal have the same number of cells.

(2) This number is the same as that of the young leaves which have not yet reached their full dimensions, but in which cell division has completely ceased. This latter supposition is very probable if species are considered in which observation shows that the leaf grows very regularly and constantly has, when mature, an approximately equal surface.

The author's experiments were made with leaves of *Robinia Pseudacacia*, *Pinus sylvestris*, *Cobaeea scandens*, *Ligustrum vulgare*, *Althaea*, *Loroglossum hircinum*, *Cercis Siliquastrum*, and have led to the following results: —

(1) The intensity of respiration of the cell, very slight in young cells,

(1) NICOLAS, *Revue général de Botanique*, Vol. XXX, No. 355, 1918. (*Author*)

increases up to a maximum, which corresponds approximately to the moment when the leaf reaches its full growth ; as the leaf grows older the intensity of respiration decreases.

By referring the results obtained to the gramme, the known results can be verified, namely that the intensity of respiration decreases with age.

(2) The respiratory quotient of leaves, slight when they are young, increases very rapidly up to a maximum, then decreases very slowly until the leaf is mature ; finally it continues to decrease regularly after the leaf has reached its full size.

The maximum in the variation of the respiratory quotient is a result which had not previously been recorded.

It is of importance to note that the respective maxima of the respiratory intensity and quotient correspond with very distinct periods of the evolution of the cell ; the former, in fact, is reached by the leaf cells when they have become completely mature, whilst the latter appears when the leaves are quite young, in the bud or shortly after its opening.

PLANT BREEDING

28 – **Plant Breeding at the Phytotechnic Station of Gayerovo, Brazil.** — ZEDNECK and GAYER, CARLOS, in *A Lavoura*, Year XXIII, No. 1-2-3, pp. 12-18. Rio de Janeiro, 1919.

The Station of Gayerovo makes comparative cultural tests and carries out individual and mass selection for cereals, peas, ground nuts, and cotton.

CEREALS. — In the work of improvement of cereals the following characters are considered : Number of culms ; number of grains per plant; weight of 1000 grains ; compactness of the ear ; weight of the ear ; weight of straw; strength and elasticity of the culms ; resistance to diseases form of the leaves ; weight of the whole plant.

Oats. — Comparative cultural tests have been carried out with the North American varieties Aurora No. 831, Fulghum No. 408, Red Rustproof No. 518-3 and also with the South American oat Excelsior of Rio Grande-de-Sol. The germination faculty of this last was 87 %, against 25, 13, and 10 %, respectively for Aurora, Fulghum and Red Rustproof. In addition to their feeble germination faculty the North American kinds proved very susceptible to rust, in strong contrast to Excelsior which resisted rust completely.

Wheat. — Barletta wheat was dealt with by mass selection with good results, and a genealogical selection was also carried out; 11 different lines are under study.

Comparative cultural tests with 4 Japanese wheats : Sgatiengo, very early (ripens in 3 months); Eshima, with large, flattened ears ; Shiroboya beardless and early, with ears like Squarehead; Shiro, like Sgatiengo, but later ; have given interesting results. Thus it has been found that the weight of 1000 grains is in grammes : Sgatiengo, 32.01 ; Eshima, 47.0 ; Shiro, 33.7 ; Shiroboya, 39.9.

Rye. — Nine pure lines are under study ; in mass selection only grains of ears weighing at least 2.3 gm. are gathered.

PEAS. — The best results are given by the kinds : — Bliss Everbearing (dwarf and prolific) ; Burst's Early Morning Star and Prosperity (very

early); sown on the 9th September the Kind Prosperity yielded its crop on November 26. The kinds Alderman, Duke of Albany, Telephone, Champion of England, Marrowfat were completely destroyed by *Erysiphe Pisi* D. C. (= *E. communis* Wallr.).

Potatoes. — In selecting potatoes the qualities aimed at are : — heavy yield good quality, and resistance to diseases. The kind Silezia fulfils these conditions. In the work of sorting the following characters are considered : — Total number of tubers ; total weight of tubers ; resistance to diseases ; weight of the whole plant ; etc.

Ground-nuts. — Varieties studied : — The ground-nut cultivated by the Nhambiguara, Parecis and Tupis indians in Matto Grosso ; Hespanhol Rasteiro ; Tennessee Red Peanut ; Gayerovo variety.

The variety cultivated by the natives of Matto Grosso is noted for the size of its seeds, four times as large as those of the common kinds, so that 100 of its seeds weigh, on the average, 357 gm. against 55.16 gm. for the variety Hespanhol, 5673 gm. for Tennessee and 6973 gm. for Gayerovo.

Cotton. — The variety Expresso is at present under study.

Maize. — Attention is directed almost exclusively to Golden Dent, with the object of preserving the purity and improving the quality of this maize, which appears to be best suited to the district. The genealogical selection has been started with the seed of a Campea Cob (prize winner at Rio de Janeiro) and of 4 other cobs selected out of 400.

At present it is possible to say that the plants produced by the Campea cob are distinguished from all the others by the vigour of their growth and, by, what is still more important, their earliness.

Other North American and Brazilian varieties, such as Dr. Assis Brazil, Horsting Prolific, Gerrick, Laguna and Loveliest are also under study.

29 – **Trials of Hybridisation Between Some Species of *Triticum*, in Denmark.** — Kaja- nus, B., in *Nordisk Jordbrugsforskning Forening*, Part 5, pp. 224-226. Copenhagen, 1919.

Results of hybridisation work undertaken since 1911 with *T. dicoccum*, *T. Spelta*, *T. turgidum*, *T. vulgare*, and *T. compactum*. The facts examined are of considerable interest, both as regards the appearance of new combinations of characters and as regards the morphological expression of each factor and the general action which they exercise in determining well defined genotypes.

From the cross *vulgare* × *dicoccum* were obtaind in F_2 forms very much resembling *Spelta* and which, crossed with *vulgare*, dominated the characters of the latter in a similar manner to what has been noted in the cross *Spelta* × *vulgare*. On the other hand, from the cross *vulgare* × *turgidum* forms of the *Spelta* type were obtained which, crossed with *vulgare*, behaved as recessives, in the sense that the hybrids resulting had the characters of *vulgare*.

Some new " Squarehead " types deserve to be noted ; they resulted from crossing *vulgare* × *dicoccum*, *vulgare* × *turgidum*, *vulgare* × *spelta*.

The hairiness of *Spelta* and the dark colour of the ears are due to a

single factor, *G*. In the hybrids *Spelta* × *vulgare* the action of this determinant is very slight, even in the homozygous state, the pubescence is confined to the upper extremity of the covering glumes and the hairs are not so dense as in *Spelta*.

Dicoccum also possesses the factor *G*, and, in addition another factor *B*, which has a simple chromogenic action, producing a red brown colouring.

Turgidum presents a new determinant, *H*, relating to hairiness: hairs long, easily seen, spread over the whole surface of the covering glume. The red brown colour of *turgidum* depends, on the other hand, on the same factor *B* as in *dicoccum*.

Regarding the action of the factors generally it wasfound that, in some crosses, certain factors unite freely according to the laws of combination of characters, while, in others, they show absolute incompatibility, that is to say, they are incapable of uniting in a single combination. Thus, in a series *vulgare* × *turgidum* the factors *H* and *B* in F_1, blended normally so that, in the F_2 generation, the ordinary divisions, forseen according to MENDEL'S law, of 9 hairy red brown individuals, 3 hairy yellow, 3 glabrous red brown and 1 glabrous yellow were noted.

In a cross "Jämtland" wheat × "Sammet" wheat an absolute incompatibility was revealed, on the contrary, between the too above-mentioned characters, which gave in F_2 hairy red brown, hairy yellow and glabrous red brown individuals in the proportion 2 : 1 : 1, while the combination glabrous yellow was excluded.

Similar phenomena are repeated for *G* and *B*. As for the colour of the grains, it depended in certain cases on a polymerous factor, namely dimerous for Sammet wheat and trinerous for Teiss wheat. The author deduces from the results of these hybridisation trials, elements which help to establish the degree of relationship between the varieties studied. There were 2 series : on the one hand *dicoccum*, *durum* and *polonicum*, and on the other hand *Spelta*, *vulgare*, and *compactum*.

30 – **Transmission of Dwarf Character in Marquis Wheat, in Canada.** — CUTLER, G. H., in *Journal of the American Society of Agronomy* Vol II, No. 2, pp. 76-78. Washington, Feb., 1919.

When he was professor at the University of Saskatchewan (Canada), the author noticed the occurrence of a dwarf plant (9 inches high) in a field of Marquis wheat. Desiring to study this phenomenon from a genetic standpoint, he selected 200 typically normal heads and sowed separately 20 seeds of each head. Even before harvest it was easy to notice the characteristic variations in some rows, specially in row No. 186, which included : — plants from 9 to 40 inches high ; normal tall plants ; dwarf plants ; intermediate plants. As a whole these plants had the characters of descendants in F_2, confirmed by the following facts : — (1) in subsequent generations of dwarf plants the proportion of dwarfs reached 100 % ; (2) the tall plants produced exclusively tall normal plants ; (3) the intermediate plants produced 25 % dwarfs (Mendelian ratio = 1

dwarf : 3 normal). Both for wheat and oats the dwarf character would, therefore, depend on a single determinant, recessive in relation with the determinant which dominates the normal growth of the plants. The occurrence of dwarf forms of wheat had previously been observed and studied by RICHARDSON and by FARRER in Australia.

31 – **"Gironde Inversable" and "Rieti Inversable", New Kinds of Wheat obtained at Nages, France.** — VIEULES, G., in *Revue internationale de génétique*, Year VI, No. 7, pp. 197-208. Paris, July, 1919.

The Director of Agriculture for the Department of Tarn recommends for that region the two wheats Gironde (from southern France) and Rieti (from central Italy). While these wheats have excellent qualities they have the defect of being very subject to lodging. The author, after having described in a general manner the work of the Central Genetic Institute of Nages in his article, announces that he has created 2 non-lodging types of *Gironde* (Gironde inversable) and of *Rieti* (Rieti inversable), which will be placed on the market in 3 years. Besides *Gironde inversable*, the author mentions other kinds of Gironde type. *Gironde aristé*, the ear of which is much longer and the appearance much superior to that of the original kind, and *Gironde doré*, which is more vigorous and earlier than the common type.

32 – **Morphological and Cytological Researches on the Hybrids *Aegilops ovata* × *Triticum vulgare*.** — BALLY, W., in *Zeitschrift für induktive Abstammungs und Vererbungslehre*, Vol. XX, Part 3, pp. 177-140, 3 fig., IV pl. Leipzig, 1919.

In 1854, at Montpellier, GODRON made the cross *Aegilops ovata* × *Triticum vulgare* successfully and he obtained in the F_1 generation plants which, fertilised with pollen of *Triticum*, gave in RF_2, hybrids with intermediate characters, but decidedly nearer *Triticum* than *Aegilops*. These hybrids remained constant in successive generations, with a gradual decrease in fertility : it was therefore a case of "intermediate heredity".

The author, after reproducing the hybrids of GODRON, submitted them to a wide cytological study ; he thus approached one of the most delicate questions of modern genetics : the transmission and the behaviour of characters in relation to the number and form of the chromosomes (1) and to the phenomena which occur in the processes which lead to the differentiation of the germ cells.

HYBRIDS F_1 *Aegilops ovata* × *Triticum vulgare*. — They are distinguished by the following characters : —

(1) Large number of shoots, as in *Aegilops*.

(2) Straw straight.

(3) Ears elongated with 5-7 spikelets (*Aegilops* has 3-5, *Triticum* has up to 15).

(4) In the lower spikelets, the glumes are prominently keeled and bearded ; in the upper spikelets the keel is scarcely apparent and the number of awns may reach 3.

(1) See *R.*, Oct.-Dec. 1919, No. 1116, which defines the cytological terms used in this article. (*Ed.*)

(5) The covering glumes have a single awn and a lateral notch (as in *Triticum*).

(6) All these hybrids have bad pollen ; the granules, slightly filled with plasma, have a wrinkled surface ; starch is completely absent.

Formation of sexual cells in the hybrids. — *Aegilops* and *Triticum* differ both in the number and in the form and size of their chromosomes. *Triticum* has 8 chromosomes, twice as big (wide) as the chromosomes of *Aegilops* which number 16.

Cross between *Aegilops ovata* and *Triticum vulgare*.

On the left : *Triticum vulgare*
On the right : *Aegilops ovata*
In the middle: Hybrid between these two species.

Prophase. — In the F_1 generation, according to present day opinion, the 8 chromosomes of the grain of pollen ought, in diacinesis, to unit with 8 of the chromosomes of *Aegilops* to constitute 8 pairs of "twins", while 8 of the chromosomes of *Aegilops* should remain isolated. However, the preparations obtained by the author did not enable him to establish with certainty whether all went in accordance with the preceding scheme. There were,

it is true, some isolated chromosomes, but it was not possible to be sure that they were precisely those of *Aegilops* and, on the other hand, the differences of form and size between the 2 groups of chromosomes do not become visible until much later. It even happens in certain cases that the " twins " are absolutely identical and almost give the impression of being a chromosome which has been divided in its length, anticipating the phenomena of the subsequent homotypic division (by a process similar to that which ROSENBERG has studied in hybrids of *Hieracium*). The dividing in two of the elements should in any case occur in one manner or another, as results from the examination of some preparations where, in correspondence with the nuclear spindle, a number of haploid chromosomes greater than 12 (4 *Triticum* + 8 *Aegilops*) is found.

During heterotypic division or of reduction, the author frequently notes the presence of multipolar spindles, and he thinks it possible to add to the already so numerous causes attributed to the phenomenon, the mechanical reason of the fact of incompatibility between the dimensions of the spindle and those of the chromosomes.

Metaphase and anaphase. — The emigration of chromosomes towards the poles is not carried out with equal speed for all elements ; the chromosomes of *Triticum* seem to reach the pole before those of *Aegilops*. In this case, it is possible that a group of chromosomes exclusively belonging to *Triticum* condense and isolate themselves with the nuclear and cellular partitions which belong to it and give rise to an element in which all the chromatic substance is derived from a single generator. In his determinations the author has examined the mother cells of pollen which are very suitable for research of this kind. We have seen above that GODRON in rehybridising F_1. *Aegilops ovata* × *Triticum* had obtained, in $R\ F_2$, a hybrid which transmitted its characters without alteration and maintained itself constant from one generation to another. The author attempts to explain this phenomenon of intermediate heredity in the following manner : — in the reduction division of the parent cells of the macrospores daughter cells may be formed, in a similar manner to what has been observed in the pollen mother cells, in which the nucleus contains substance of *Triticum*. only. These alone will be capable of developing. Now if an egg cell so formed and consequently containing 4 chromosomes of *Triticum* alone is fertilised by pollen of *Triticum* containing 8 chromosomes, an individual with 12 chromosomes (diploid) will be obtained which is absolutely homozygous and constant. In the present case such a hybrid constitutes the species *Aegilops speltaeformis*.

Homotypic division. — The boundary line between the processes of heterotypic and homotypic division is not very clearly defined, because of numerous irregularities which occur in the distribution and in the movement of the chromosomes which often cause the formation of elements constituted by chromatic substance derived from one only of the two generators.

The renewing of the homotypic divisions which takes place in the tetrads already formed and which leads to the formation of polynuclear pollen grains should be noted.

Up to the last stages of meiosis the differential characters of the *Triticum* and *Aegilops* chromosomes, which have become increasingly noticeable, remain unaltered and thus give a further contribution to the theory of the individuality of the chromosomes.

33 – **The Occurrence of Dwarf Plants and the Transmission of that Character in Pure Lines of Victory (Seger) Oats, in the United States.** — WARBURTON, C. W., in *Journal of the American Society of Agronomy* Vol. II, No. 2, pp. 72-76, 1 pl. Washington, Feb., 1919.

In 1916, at the Aberdeen Station (Idaho), the author noticed, in a row of 20 plants of Victory (= Seger of Svalöf) oats, the occurrence of 8 quite abnormal specimens. The plants tillered abundantly, so that low tufts were formed with rather stiff erect leaves at the base ; the culms, few in number, are less than 10 inches in height and bear generally a very small inflorescence with 3 or 4 spikelets ; these dwarf plants are very late and frequently their seed is not ripe before the first frosts. In 1917, the author sowed a few matured seeds and obtained progeny all of which were dwarf. In the original row of dwarf plants there were 12 normal (tall) plants ; 40 seeds were taken from each of 10 of these plants and sown in 10 separate rows. In 1917, the resulting plants were examined and it was found that 4 of the plants had produced normal plants exclusively, while the other 6 had a mixed progeny of tall plants (168) and dwarf plants (66), in the ratio 2.55 : 1, which corresponds fairly well with the Mendelian ratio 3 : 1 observed in F_2 of the hybrids with 2 allelomorphs, one of which is dominant. In this cases the " normal " character would be dominant.

Successive generations would then be constituted by homozygous plants (*dwarfs* and *normal*) which remain constant, and by heterozygous plants (*normal* in appearance owing to dominance) which would divide in the following generation into dwarf and normal plants.

Subsequent research undertaken at other Stations (Ithaca and St. Paul) confirms the results obtained at Aberdeen. However, the author cannot fix the causes or cause of the sudden appearance of abnormal plants in Victory oats.

34 – **Transmission of Maternal Characters in *Humulus japonicus* var. *albomaculata*, in Denmark.** — WINGE, O., in *Comptes rendus des travaux du Laboratoire Carlsberg*, Vol. 14, No. 2, pp. 2-11, 3 fig. Copenhagen, 1919.

Normal *Humulus japonicus* with green leaves (= *norm*), crossed with the *albomaculata* variety (*Humulus japonicus albomaculata* = *albm*), produces in F_1 progeny exclusively normal in the case ♀ *norm* × ♂ *albm*, and progeny exclusively mottled (with white green watered leaves of the *albomaculata* type) in the case ♀ *albm* × ♂ *norm*.

In F_2 there were :

♀ *norm* (*norm* × *albm*) × ♂ *norm* (*norm* × *albm*) = *norm* 78, *albm* 0
♀ *norm* (*norm* × *albm*) × ♂ *norm* (*norm* × *albm*) = *norm* 31, *albm* 0
♀ *norm* (*norm* × *albm*) × ♂ *albm* (*albm* × *albm*) = *norm* 32, *albm* 0
♀ *albm* (*albm* × *albm*) × ♂ *norm* (*norm* × *albm*) = *norm* 0, *albm* 29

The *albomaculata* character therefore is only transmitted on the maternal side and the examination of the progeny up to the F_1 generation fully confirms that assertion. This method of transmission can be explained if it is assumed that the character in question is absent from the nucleus of the egg cell (in this case the Mendelian laws would hold good), but is present in the cytoplasma. In this case it would still have to be proved whether the phenomenon is attributable to the chromatophores or to the plasma itself. The entire absence of *white* forms (albinos) and of *normal* forms in the progeny, which, in any case, are *albomaculata*, shows that this latter character is really due to a special structure of the plasma of the egg cell.

35 - **Selection of Coffee and Cocoa at Surinam, Dutch Guiana.** — Stahel Geroldi in *Departement van den Landbouw in Suriname, Bulletin* No. 36, pp. 1-23. Paramaribo, Feb., 1919

By hybridisation followed by selection, shrubs also can be improved in respect of the yield and quality of their products. But the time required to effect these improvements is naturally very long, so that to obtain practical and assured results the work must be continued for several decades. On the other hand, vegetative reproduction, by graft, of individuals selected for their superior qualities, offers a quick and sure method of improving plantations.

Methods of this kind were and are applied on a large scale and with success in the United States, especially in Florida and California, in replanting orange gardens. In the article reviewed, the author published the results obtained at Suriman by applying these methods to the selection of coffee and cocoa shrubs. Of the former the Liberian species is cultivated ; of the latter the " Forastero " variety ; both are characterised by great variability which offers a wide field of study in selection. For example, the author gives the following data collected by Folmer (Jagtlust coffee plantation). From seeds of Liberia-K5, characterised by the shape of its berry (oblong and not globular), 80 plants were raised not one of which had this character. Moreover, very great divergence was noted regarding the yield and quality of the produce. Thus in 27 plants examined, the yield varied between 8 kg., and 11.6 kg. and the weight of 100 berries varied between 24.9 gm. and 39.1 gm. On the other hand, taking the plants individually, it was noticed that good yielding plants maintained their superiority from year to year over less productive plants, as is indicated in Table I which relates to the cocoa plant.

There are therefore noticeable and constant differences between the shrubs so far as yield is concerned. Hence the opportunity and the possibility of determining the best shrubs which should furnish grafts for the progressive improvement of the plantations.

Coffee shrubs. — For each plant the following points were considered : — (1) The weight (kg) of berries produced ; (2) the weight (kg) of marketable produce (obtained by exposing the harvested berries to temperatures of 60°-70° C. for 1 or 2 weeks) ; (3) the yield, that is to say the quantity of marketable produce expressed by the percentage of the crude

produce; (4) the weight in grammes of 1000 berries; (5) the age of the bearing plant.

TABLE I. — *Productivity of cocoa shrubs : number of pods per tree in* 1917 *and* 1918.

Number of the shrubs	1917	1918	Total for 1917 and 1918
C_1	232 pods	198 pods	430 pods
C_2	116	86	202
C_3	221	145	366
C_4	169	141	310

C_8	100	27	127
C_9	297	227	524
C_{10}	352	218	570

In 4 different plantations (Jagtlust, Wederzorg, Geijersflijt, Guin, Vriendsch), the author had studied 28 bearing plants, from which he selected the 13 plants noted in Table II, which were considered to be the best.

TABLE II. — *Productivity of coffee shrubs: yield of the* 13 *best bearing shrubs.*

Name of the plantation and numbers of the shrubs	Weight of seeds per shrub	Quantites of merchantable produce per shrub	Yield	Weight of 1000 seeds	Age of the bearing shrub
	kg.	kg.	%	mg.	year

» » K_8	17.1	1.6	9.2	207	»

COCOA SHRUBS. — In selecting the bearing shrubs the following data were considered : — (1) Number of pods; (2) weight (kg) of marketable produce (seeds dried at 60°-70° C.); (3) weight (kg) of merchant produce from 100 pods; (4) weight (g) of 100 seeds; (5) age of the bearing plant; (6) size of the shrub (1 = large, well developed ; 2 = medium, or small).

85 cocoa shrubs were examined in 19 plantations ; the 15 indicated in Table III were chosen as bearing plants.

In choosing the bearing shrubs, besides the total amount of the crop, the yield and the weight of the seeds, other characters, such as for example, resistance to diseases, etc. should be taken into consideration. Thus, in Culturtuin plantation the shrub C6 giving a low yield (3.7 kg. of marketable produce) was selected because of its resistance to the disease called " krulloten ", caused by *Marasmius perniciosus*. Its immunity was confirmed by artificial infection tests.

TABLE III. — *Productivity of cocoa shrubs : yield of the 15 best bearing shrubs.*

Name of the plantation and numbers of the shrubs	Number of pods per plant	Weight of marketable produce per plant	Weight of marketable produce per 100 pods	Weight of 100 seeds	Age of the bearing shrub	Size of the shrubs
		kg.	kg.	gm.	year	
Berlijn C_3	153	5.0	3.3	117	20	2

C_{19}	199	7.6	3.8	119	35	1
Susannadaal C_1	244	13.7	5.6	125	45	2

The author proposes to continue the work of selection with the object of separating the best shrubs, which will then be used as grafts and thus continue the progressive renewal of the plantations.

36 - **" Connecticut Havana No. 38," a New Variety of Tobacco Produced in the United States by crossing Two Types (No. 26 and No. 27), obtained by Mutation from the Variety Connecticut Havana.** — JOHNSON, JAMES, in *The Journal of Heredity*, Vol. V, No, 6, pp. 281-288, 3 fig. Washington, June, 1919.

The two types of tobacco " Selection N°. 26 " and " Selection N°. 27 " probably originated by mutation from the variety Connecticut Havana at the Wiconsin Agricultural Experiment Station (1919).

No. 26 is superior to the original variety in the size of its leaves and inferior to it in their number ; on the other hand No. 27 has more leaves than Connecticut Havana, but the leaves are rather small.

There was evidently a chance of uniting in a single plant the positive characters of No. 26 and 27, by eliminating the negative characters. The

cross 26 ♀ = 27 ♂ made in 1909, gave in 1910, in the F_1 generation, a plant which very closely approached the desired type and which was distinguished by the number 38. In F_2 and following generations, the plant reproduced in conformity to the type without apparently presenting the Mendelian division of 3 groups of intermediate plants, plants resembling the male parent and plants resembling the female parent. This phenomenon may be explained in two ways : —

(1) The 3 groups of pure plants differ in anatomic and histological values which cannot be demonstrated easily.

(2) All the F_2 hybrids are identical, since commencing with F_2 the differential factors are fused in the zygote (heterozygote) so as to constitute a single new factor. This is called " blended or blending inheritance ". However it may be, the fact, independently of the explanation of the causes, remains substantially the same : the hybrids 26 × 27 are for practical purposes fixed.

After 4 years of comparative tests and control, type N°. 38 was widely distributed to growers in 1916, and the results obtained confirm the expectations; this new tobacco may therefore be recommended for all parts of Wisconsin.

Without differing too greatly from the best local varieties, No. 38 is distinguished by the following characters : —

(1) Erect leaves, which makes it occupy less space and facilitates field work.

(2) The leaves are almost uniform in size from the top to the bottom of the plant and they are broader than the leaves of Connecticut Havana.

(3) Its leaves are larger than those of Connecticut Havana, and they are also more numerous (on the average 1 or 2 more per plant).

(4) In yield it is 7 to 10 % better than the original variety.

The following table, which sums up the data obtained and gives the averages of 8 years, enables a comparison to be made of the characters of Connecticut Havana (No. 33) and No. 26-27-28 (= 26 × 27), respectively.

	Number of leaves	Size of the leaves (Average of bottom, middle and top leaves)		Breadth index of leaf
		Length, inches	Width, inches	
No. 26	14.2	20.0	11.3	56.5
No. 27	18.0	18.0	9.6	53.6
No. 38	16.9	19.1	10.6	55.8
No. 33	15.5	18.2	9.8	53.8

The value of the new type is also shown by the rapid manner in which its cultivation has spread. It was estimated that 10 000 acres would be sown with it in 1919 out of a total of 40 000 to 45 000 acres under tobacco in the State of Wisconsin.

37 - **Vigorous Growth Compensating for Sterility in Hybrids of Species of Foxglove (*Digitalis purpurea* and *D. lutea*).** — BLARINGHEM, L., in *Comptes rendus de l'Académie des Sciences* Vol. 169, No. 10, pp. 481-483. Paris, 8 Sept., 1919.

Crosses between species, which produce mixed sterile plants, often lead, by a sort of organic compensation, to the excessive development of roots, stems, leaves and flowers.

The author has studied, from this standpoint, the direct hybrid *Digitalis purpurea* × *D. lutea* and the reciprocal hybrid *D. lutea* × *D. purpurea* obtained in 1909 from the same plants, taken alternately as male and female parent, at the laboratory of plant physics at Meudon.

Owing to the absolute sterility of the ovaries and stamens of the hybrids, the two crosses produced only a first generation consisting of 120 plants, which exhibited several interesting peculiarities : —

(1) The whole collection of hybrids, direct and reciprocal, is remarkable for its homogeneity for the uniformity of growth of the individual plants. NAUDIN'S law regarding the uniformity of hybrids of the first generation is remarkably illustrated in this case.

(2) Differences of origin, well shown in the opened flowers are not indicated by any striking peculiarity in the vegetative organs. As the differences bear only on the floral and deciduous organs, the law of equivalence of direct and reciprocal hybrids, enunciated by NAUDIN for a large number of fertile hybrids, is partially applicable to these sterile hybrids.

(3) The hybrids of the species *D. purpurea* and *D. lutea* have giant and infantile characters. The continual production of shoots in hybrid root stocks which spread in tufts enabling them to be rapidly multipled by division, and the almost indefinite production of flowers on the flowering stalks which do not die, but dry up in the August sun, are proofs that the tissues of hybrids remaini n an infantile state. The author has previously brought to notice a similar example (*Specific value of various groups of wheat* [*Triticum*]. Memoir of the Laboratory of Agricultural Biology at the Pasteur Institute, 1914, p. 44) in the almost sterile hybrid *Triticum monococcum* × *T. durum*, and has shown that the tissues in that case remained in an state characteristic of the infancy of one of the progenitors.

(4) At the end of July, 1919, almost all the stalks developed in the hybrids showed well marked characters of fascies.

To sum up, hybridisation between species of foxglove, which entails sterility, causes excessive growth of vegetative tissue with all the characters which belong to young well nourished organs.

38 - **Origin, Production and Value of the Seeds of Conifers.** — PICCIOLI, L. (Professor of sylviculture, alpiculture, and technology, at the Royal Forestry Institute of Florence), in Extract from *Annali del R. Istituto superiore forestale nazionale*, Vol. IV-V, pp 185, 190, fig. bibliography. Florence, 1920. AGRICULTURAL SEEDS

Monograph on the seeds of conifers containing the following chapters : Importance of heredity of mutations. — Effects of origin — Prohibition of exportation. — Private, commercial, and State production — Importance of the choice of trees for the quality of seeds. — Periodicity of abundant seedings, and causes which determine them. — Collection of fruit. —

Extraction of seeds from their cones. — Sorting. — Volume, weight and production, per unit of fruits and seeds. — Fertility, lasting power, and preservation of seeds. — Frauds, and the utility of a control station — Morphological characters for recognising seeds.

This last chapter, which contains numerous data, may be useful referred to in the work of control of seeds.

The publication ends with a long bibliography.

STARCH CROPS

40 - **Experiments in the Cultivation of Various Kinds of Potatoes from the Canary Islands.** — Bois, D. in *Bulletin de la Société Nationale d'acclimatation de France*, Year LXVII, No. 9, pp. 273-280 2 figs. Paris, Sept., 1919.

Results of experiments in the cultivation of potatoes from the Canary Isands announced by the author in a preceeding article (1).

A. Experiments in 1918 at the Paris Museum. — Planting took place on May 10, in light soil, manured the preceeding autumn; harvest on November 5.

(1) " Papa palmera ", 5 plants. Total crop: 51 tubers weighing altogether 3.528 kg. or on an average 720 gm. per plant; violet skin, yellow flesh, average quality fairly good.

(2) " Papa blanca " 5 plants. Total crop: 55 tubers = 1.406 kg., or 281 gm, per plant, therefore a crop very inferior to that of the preceeding variety. Colour uniform yellowish-white, pale yellow flesh, fine starch, very good quality.

(3) " Papa negra " 2 plants only, 2 tubers not having sprouted. Total crop: 11 tubers × 700 gm., that is 63.65 gm. per tuber and 350 gm. per plant. Shape irregular, colour violet pink, yellow flesh, no information regarding the quality.

The two other varieties, " Papa melona " and " Papa de Baya ", were received too late to be planted (end of June, 1918).

B. Experiments in Algeria, Tunis and Morocco. — The results are not yet known. It is interesting to note that the varieties of Canary Island potatoes are suited, if not to a tropical climate, at least to a subtropical one. They would therefore be valuable if this suitability allowed of their cultivation in those colonies where European varieties do not succeed, or give only poor results. This can only be learnt by experiment.

C. Experiments in 1919 at the Paris Museum. — The " Papa palmera " variety has given a fairly high yield but its irregular shaped tuber, and its medium quality are fairly grave defects; it would only be really interesting if fresh trials, in a more favourable season, showed that it was a good cropper and if its quality was improved, by cultivation in a more suitable soil. The " blanca " variety produced fewer tubers, which were, however, much more regular and of good quality.

(1) See *R.*, Feb. 1919, No. 194. (*Ed.*)

41 – **The Cultivation of Cotton in Australia.** — *The Board of Trade Journal*, Vol. CIII, 1194, p. 485. London, Oct. 6, 1919. FIBRE CROPS

The possibility of permanently establishing the cotton-growing industry in Australia will probably be thoroughly tested in the near future. Efforts to establish the cotton-growing industry in Queensland on a successful footing, however, have not hitherto met with much success.

There was a brief period when, as a result of the American Civil War, Queensland exported 26 000 000 lb. of ginned cotton, valued at £1 300 000, but by 1914 the area under cotton had shrunk to 214 acres, the yield to 35 230 lb. of unginned cotton, and its value to £881.

Despite this discouragement the opinion is held that there are few, if any, difficulties in the way of extensive cotton growing in Australia, particularly in the province named and in the Northern Territory and Western Australia, where both soil and climate appear excellently suitable.

In reply to the assertion that the yield of cotton in Australia, as shown by statistics, indicated inferior conditions or methods, it has been stated that Queensland obtained a much larger yield per acre than can be obtained in the United States of America, and that natural conditions in Queensland would more than compensate for higher cost of labour than in other countries.

The Commonwealth Government has endeavoured to encourage the industry by offering a bounty of 10 per cent. on the market value of cotton grown, and ginned in Australia, but only £21 had to be paid out in 1914. The high prices reached in the cotton markets during the war led to extended cultivation, and the Queensland Department of Agriculture Ginnery received 166 000 lb. of cotton in 1918, as compared with 9 500 lb. in 1914.

The high cost of hand-picking seems to be the chief obstacle in the way of the industry's establishment on a large scale. This is partly due to the higher wages paid in Australia than in the other cotton-growing countries, but it is thought that the difficulty could be overcome by encouraging farmers to grow, say, not more than about 10 acres of cotton, in addition to other crops, so that a family of four could easily pick the cotton without outside help. Inexperience, and the lack of skilled pickers too, play a part in running up costs. The introduction of an efficient mechanical picker would help materially towards putting the industry on a successful footing, though mechanical picking would necessarily be restricted to the varieties of cotton in which the calyx opens wide and the seeds are relatively loose.

As regards quality that of Queensland cotton is stated to be very high. The Commonwealth's imports of cotton piece-goods in 1913 exceeded 3 000 000 in value (duty free from the United Kingdom, and 5 per cent. tariff from other countries). Australia has no cotton-manufacturing industries at present.

The Commonwealth Board of Trade does not consider present prospects of materially increasing cotton production very promising, and enquiries in the United States of America have led to the opinion that the discovery

of a mechanical picker for good crop cotton is unlikely, in view of the fact that selection by eye of the riper pods is a necessary factor. At the same time, Australia has its parallels as regards soil and climate in many of the cotton-growing districts of the United States of America, and, under similar conditions, the same types of cotton (there are some 200 different varieties) could probably be cultivated successfully in many parts of Australia.

The experts of the American Bureau of Plant Industry have advised the Board that before the cotton-growing industry can be successfully established in Australia, experiments will have to be made in exactly the same way as has been done with wheat growing and wool production.

42 - **Cotton in the French Settlements of Oceania.** — *Bulletin de l'Office colonial*, Year XII, No. 135, pp. 190-191. Melun, 1919.

Owing to the scarcity and dearness of labour, the cultivation of the cotton plant is being more and more abandoned in the French settlements in Oceania; and production has continually decreased during the last ten years as is shown by the figures below, regarding exportation from 1910 to 1917.

Year	Weight	Value	Year	Weight	Value
1910	78 276 kg.	97 599 fr.	1914	17 320 kg.	28 673 fr.
1911	27 536	42 047	1915	8 485	11 115
1912	31 977	55 586	1916	10 565	18 522
1913	26 700	46 104	1917	4 112	18 224

43 - **Fibre Plants and Products, and Textiles of Indo-China: Cotton Plant.** — Crevost, Ch. and Lemarié, Ch., in *Bulletin économique de l'Indochine*, Year XXI, New Ser, No 136, pp. 365-401, 3 plates, 1 fig. Hanoï-Haïphong, May-June, 1919.

This article is the continuation of the first volume of the *Catalogue des Produits de l'Indochine* by the same authors (1) and will form the 1st part of the 2nd volume of that publication.

In the *Flore générale de l'Indochine*, M. Gagnepain notes 4 species of cotton-plant, distributed in the native crops of the different countries of the Union: —

(1) *Gossypium indicum* Lamk., grown in Tonkin, and Cochin-China; short staple, very adherent to the seed.

(2) *G. arboreum* Lin., grown in Siam and Cambodia.

(3) *G. hirsutum* Lin., cultivated in CochinChina and probably also in Cambodia; fibre very adherent to the seeds, rarely longer than 25 to 27 mm., of excellent quality.

(4) *G. vitifolium* Lamk, with the varieties *acuminatum* and *tricuspidatum*, cultivated in Cochin-China, in Cambodia and Laos.; cotton slightly adherent, of excellent quality.

Attempts to introduce foreign varieties (American, Egyptian) have only given poor results. It is thus easier and more profitable to improve local kinds which have been tried for a long time. Cambodian cottons are parti-

(1) *Catalogue des Produits de l'Indochine*, Vol. I. *Produits alimentaires et Plantes fourragères*, by Ch. Crevost and Ch. Lemarié, Imprimerie d'Extrême-Orient, Hanoï, Tonkin (*Ed*).

cularly esteemed in Japan. The communication made on this subject, at the Colonial Agricultural Congress at Paris, in 1918, by M. MARTIN DE FLACOURT, head of the agricultural and commercial services of Cambodia, showed the efficiency of the method (1).

The valley of the Mékong offers many sites and lands, which are suitable to a profitable cultivation of cotton. The mountainous lands of Tonkin and the plains of Thannh-hoa, where, however, this textile has been produced on a large scale from time immemorial, are doubt less less favourable, but it is certain that the irrigation undertaken by the "Services d'hydraulique agricole", in the provinces of Thannh-hoa and elsewhere (2) will favour a crop, contrived so as to obtain maturity in the dry season.

The growth of the plant requires, from planting to harvest, 4 to 6 months, according to locality. It is therefore possible, at least for countries with a regular dry season, to find a favourable time for sowing. Fertility, and especially a suitable proportion of humus, are very frequently lacking in the soils which the Annamites devote to the cotton plant. Experimental cultivation has shown that "sideration" allows of a rapid improvement, in a soil reputed unsuitable to that crop., and of bringing it to bear fine crops. Preference should be given to leguminous plants such as the soya bean, mungo pea, "voehms", and more especially, the "Tonkin bean". Many other native leguminous shrubs are available to planters.

There is much to be done to increase the yield of the cotton plant in Indo-China.

While in India the annual production of similar varieties may reach 165 kg. of cotton per ha. it averages 123 kg. at Thanh-hoa, in Cambodia it does not exceed 125 kg. in alluvial soils, but recent cultivation in red soils in the Kratié, district with selected seed, gave 218 kg. per ha.

In Cambodia, trials undertaken by M. MARTIN DE FLACOURT are most interesting. Giving up inundated land, he turned his attention to high land, where he has obtained excellent results, by altering the sowing season, so that the cotton plants reach maturity in the dry season.

Commercial examination has graded these cottons above similar kinds from Africa, comparing them to Good Middling American 28-29 mm.

Laos cottons sometimes. have an unusually long staple; unfortunately this country is not yet open to colonisation, for lack of suitable means of communication.

In Tonkin the cultivation of the cotton plant is of slight importance. In mountainous districts the variety "Bong-ro" has a remarkably long staple.

In Annam, the cotton plant is scattered over the whole country, without being anywhere cultivated on a large scale.

(1) See *R.*, Dec. 1918. No. 1555. (*Ed.*)

(2) As regards agricultural irrigation in Indo-China see (1) *L'hydraulique agricole en Indochine* by L. COSTANTIN, Paris, Congress of Colonial Agriculture, 1918, Hanoï Series, No 15, Hanoï 1918. (2) *Travaux secondaires d'hydraulique agricole en Cochinchine* by J. ROBIN, Paris, Congress of Colonial Agriculture, 1918, Saigon Series, 1918. (*Ed.*)

In Cochin-China it is only in the province of Baria that regular cultivation of cotton is found.

The introduction of hand-ginning machines among the natives has not been crowned with success. Of the different machines tried, M. MAGEN considers that the MACARTHY roller and knife system, subject to some improvements, meets the needs of Indo-China best ; up to date only Cambodia has made important exports. Before the war, from 1549 tons exported in 1911 the export had increased to 10 085 tons in 1913.

The cotton question in the Far East being of particular importance at the moment, the authors rightly think that Indo-China should not let itself be beaten by its rivals.

44 - **Cotton Production in Asiatic Russia** — *Bulletin de l'Office colonial*, Year XII, Nos. 138- 139, pp. 455-456. Paris-Melun, June-July, 1919.

In 1912, 535 000 ha. had been planted under cotton in Russian Turkistan and Transcaucasia ; they yielded about 440 000 t. In 1917, the area planted had fallen to 337 000 ha, a decrease of 37 %. In 1918, cotton plantations had again to give place to cereals in consequence of the stoppage of all importation of wheat, and fear of famine. It is, therefore, probable that the cotton fields were still less in area than those of 1917, which had not yielded 275 000 t.

Deducting the amount required for the manufacture of local cotton goods, this last figure leaves only 190 000 t for home spinning and weaving, including that of Russia in Europe. In normal times, the Russian spinning mills absorbed the normal production of the Asiatic colonies, and imported, 178 000 t. of American, Egyptian, and Persian cotton as well.

45 - **Cotton Cultivation in the Belgian Congo.** — BALLON, F., in *Bulletin de l'Association des Planteurs de caoutchouc*, Vol. VI, No. 8, pp. 12-13. Antwerp, Aug., 1919.

From the beginning of its foundation, the Congo State thought of developing cotton cultivation in is territories. But the experiments tried in Lower and Upper Congo were unfavourable. Experiments were undertaken in 1915, by M. FISHER, in the eastern province at Nyanwe farm (Maniéma), where the State owns 500 head of cattle, and has at disposal a considerable extent of light land, apparently very suitable for the crop. The climate of Maniéma is more uniform and the rainfall is greater than in the Lower Congo ; labour is more abundant and better there. Experiments showed that the soil and climate of this region were very suitable for cotton cultivation.

Two varieties " Triumph " and " Simpkins ", short staple American cottons, called " Upland ", were found to be very suitable to the climate and soil of that region.

MM. FISHER and BLOMMAERT induced the natives to cultivate cotton, and they showed themselves well satisfied with the sum of money brought in by the small areas cultivated, which had given them practically no trouble.

The first Maniéma cottons reached the Liverpool market in 1916, and were in good demand. They were graded with Middling American.

Cultivation has progressed in a remarkable manner; the area plantde by the natives increased from 45 ha. in 1916 to 500 ha. in 1917, 1000 in 1918, and, apparently, about 1500 in 1919.

Other experiments were made after 1916, with success, in the two districts of Sankurn and Kasai, and for 1919, on a cultivated area of 1500 ha., a production of 600 to 700 metric tons of cotton may be expected.

Two ginning plants were bought in the United States in 1918.

A third promising region for cotton is found in the north of the colony in the Uele districts and experiments will be attempted there before long.

46 – **Yield of Sisal.** — I. WATKINS, in *Tropical Life*, Vol. XV, No. 3, pp. 34-35. London, March, 1919. — II. *Bulletin économique de l'Indochine*, Year XII, N. S., No. 136, p. 489. Hanoï-Haïphong, May-June, 1919.

I. — Experiments made with the object of improving the production of sisal by manuring and especially by returning to the soil the " bagasse " or pulp remaining after the extraction of the fibre (1).

With regard to the yield in dry fibre, the author states that in Yucatan the yield is commonly about 50 lb. per 1000 leaves. With certain selected leaves the yield may be as high as 100 lb. More frequently from plants of 5 to 7 years old, the most productive age, 75 lb. per 1000 leaves and half a ton to the acre are obtained. It is hoped, with improved machinery, to extract a minimum of 7 to 8 % of fibre from the leaves instead of the usual minimum of 4 to 5 %.

The author himself has found in the Caicos islands, situated to the south of the Bahamas and east of Cuba, that the average yield of dry fibre would not exceed 30 lb. to 40 lb. per 1000 leaves; the percentage would be 4 %; the yield per acre, with 1500 plants, would vary from 675 lb. to 900 lb. per annum.

These calculations are based on the fact that each plant produces, during its life time, about 15 leaves a year.

According to the author, the average number of leaves which each plant can yield annually without injury would be: — 1st cutting, 30 to 40 leaves; 2nd cutting, 10 to 15; 3rd cutting, 7 to 10.

II. — The article dealt with above is summarised and discussed in the *Bulletin Economique de l'Indochine*.

The percentage yield of fibre of green leaves is ordinarily 4 to 5 %. The difference between this percentage and the 7 to 8 % spoken of by Mr. Watkins seems too great, considering the small proportion of fibre which remains in the waste.

Some 15 leaves annually per plant seems hypothetical and difficult to realise, since the life of the agave varies between 7 and 25 years according to locality, the variety grown and the method of cutting. A yield of 30 to 40 leaves for the first cutting is likely to injure the plant.

(1) For utilisation of sisal refuse otherwise than as manure (in particular the production of alcohol), see *R.*, August, 1918, No. 904. (*Ed.*)

47 – **Cultural Experiments with Textile and Oil-bearing Plants in Sjaelland, Denmark.** — JACOBSEN, A. P., in *Beretning om Landboforeningarnes Virksomhed for Plantevalen paa Sjaelland*, 1918, pp. 543-544. Copenhagen, 1919.

Results of a series of cultural experiments, made with white mustard, sunflower, flax, and hemp, in Sjaelland (Denmark), in 1918.

WHITE MUSTARD. QUANTITY OF SEED: — Comparative experiments with 4-8-12 kg. per ha. With an increasing quantity of seed sown, the yield was also increased, and gave respectively 1031-1218-1312 kg. per ha. Manuring per ha.: — 100 kg. of superphosphate and 100 kg. of 20 % potash salt. Sowing May 22; harvest October 9.

SUNFLOWER: TIME OF SOWING: — By sowing on April 14, May 1 and 8, 1700-1650-626 kg. of seed per ha. were obtained respectively; early sowing is therefore advised.

FLAX. TIME OF SOWING: Sowing was done on the April 25, May 8 and 23: reaping took place on August 6 and 16, and on September 2, with the following results: —

1st sowing	1475 kg. of seeds	3225 kg. of stalk	900 kg. waste
2nd sowing	1225 » » »	3175 » » »	900 » »
3rd sowing	1175 » » »	3650 » » »	925 » »

The first sowing gave the finest fibre, the 2nd slightly inferior results: lastly the 3rd yielded plently of fibre but of a slightly coarser quality. The later the sowing the smaller the yield of seed.

HEMP. TIME OF SOWING: By sowing on April 30, 1.40 kg. of seed to the ha., 168 00 kg. of stalks per ha were obtained; on the other hand, sowing later, on May 14, scarcely half that quantity, 8360 kg. was obtained.

PLANTS YIELDING OILS, DYES, TANNINS, ETC.

48 – **Cultivation of Flax for the Manufacture of Linseed Oil in the United Kingdom.** — VARGAS EYRE and MORRELL, R. S., in *The Journal of the Board of Agriculture*, v. XXVI, N° 4, p. 420-428. London, July 1919.

The British Flax and Hemps Grower's Society, Ltd. has undertaken a series of investigations on the cultivation of flax for production of seed and its utilisation from technical and economic standpoints in view of the shortage of fats during the last few yearas.

Several varieties of indigenous and imported liuseed was in the first place experimented with at Wye College. Table I shows the comparative values of the different types of linseed investigated.

TABLE I. — *Comparative values of types of linseed investigated.*

Type of seed	Seed Yield per acre		Percentage of oil	Oil per acre
	cwt.	lb.		cwt.
Moroccan	12	25	42,9	5.25
Dutch	11	86	37.7	4.43
La Plata	14	70	42.8	6.26
Steppe	13	53	41.5	5.60
Baltic	6	28	34.0 to 35.6	2.18

The linseed obtained compares favourably with imported linseed; in size of seed and in oil content English grown linseed is absolutely superior to imported linseed, as will be seen in Table II.

TABLE II. — *Comparative values of imported linseed and English linseed.*

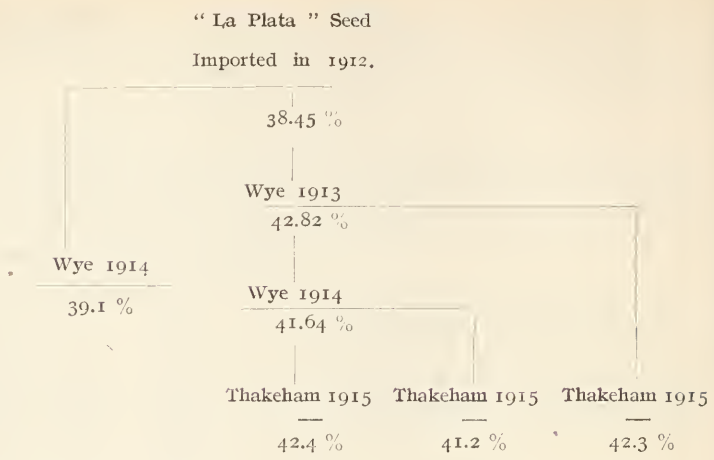
	Weight of 1000 seeds	Oil content per cent.
	gm.	
Seed of "La Plata" imported in 1913. . .	6.108	38.45
English grown linseed raised from the above imported sample on 4 different farms . . .	8.840	42.80
	9.204	39.69
	7.712	37.72
	8.744	41.35

Similar results to those in Table II were obtained in 1914 and 1915 on experimental plots in various places in England; in 1916 on 9 farms which grew "La Plata" linseed on a large scale, the results given in Table II were confirmed, as is shown in Table III.

TABLE III. — *Comparative values of imported linseed and English linseed.*

	Weight of 1000 seeds	Oil content per cent.
	gm.	
Seed of "La Plata" imported in 1916 . . .	6.4210	38.8
English grown linseed obtained in quantity from the above imported seed on 9 farms	7.1602	41.5
	8.5324	40.5
	8.1771	39.7
	7.6272	42.1
	8.2201	42.4
	7.9630	41.3
	7.1055	39.4
	7.7637	39.7
	8.3570	39.8

Further, cultivation experiments with "La Plata" seed made from 1912 to 1915 have shown that the high yield of oil of this variety in England is constant and does not decrease in successive generations as is shown in the following diagram relating to the oil content of linseed grown in successive crops at Wye, in Kent and at Thakeham, in Sussex



These results prove that the value of English linseed as a source of oil is very high. If all the oil is expressed; a yield of 50 to 70 gallons of oil per acre may be expected, or; if the linseed is pressed to form a standard cake, a yield of 35 to 45 gallons on the basis of an average oil content of 40 %.

TABLE IV. — *Comparative yield in oil according to the method of pressing.*

Yield when totally expressed		Yield under pressure leaving 10 % of oil in the cake	
Cwt. of seed per acre	Gallons of oil per acre	Cwt. of seed per acre	Gallons of oil per acre
10	48	10	36
15	72	15	54
20	96	20	72

In view of the scarcity of oil the authors advise total expression and the addition to the cake of a less valuable oil or fat for cattle food. Regarding the importance of the cultivation of linseed in the rotation or in crops combinations, the authors instance the heavy crops of wheat obtained following linseed on clay soil and on newly ploughed pasture land, and conclude therefrom that the cultivation of this industrial crop can indirectly render remarkable service to English agriculture.

Regarding the cost of cultivation, the data collected by the above-mentioned Society indicate that, in a large number of cases, the average cost is £8.10 *s.* per acre ; in any case the figure should not exceed £10 per acre.

At the present price of £45 per ton, the average gross return per acre would be £33.15 *s.*, without taking account of the straw or the chaff. The

yield of straw varies from 9 to 21 cwt. per acre according to the fertility of the soil, its tilling and its manuring. The present price of the straw in bales is from £4 to £5 per ton. There is, in addition, about 7 ½ cwt. of chaff per acre selling at £5 per ton. The straw and chaff thus and £5 per acre to the gross return, brings the total up to £39 per acre.

THE COMMERCIAL VALUE OF THE LINSEED OIL PRODUCED. — The examination of the oil produced during the experiments has extended over the crops of 3 years : a small quantity in 1915, half a ton in 1916 and 3 tons in 1917. The properties of these oils are similar to those of superior-quality Baltic oils.

If the quality of the seed is maintained, linseed oil made from English —grown seed will always fetch the highest market rate. The superiority of the quality will easily out-weigh the disadvantage arising from the higher cost of production. The characteristic properties of Baltic linseed oil causes it to be in special demand with makers of high grade paints and oil colours. The high quality of the product examined warrants the prediction that English manufactures will be independent of linseed oil from Russia. The cake produced for cattle food is equal to the best at present on the market.

CONCLUSION. — England is in a position to produce a considerable quantity of linseed oil of superior quality.

49 - **On the Utilisation of " Sump ". (*Balanites aegyptiaca* Del).** — AMMANN PAUL in *L'Agronomie Coloniale, Bulletin mensuel du Jardin Colonial*, New Ser., Year IV, No. 16, pp. 42-45. Paris, Sept.-Oct., 1919.

Balanites aegyptiaca, a tree 16 to 20 ft. in height, grows in a certain number of semi-desert regions of tropical North Africa, as well as in India and Burma. It is fairly widespread in Senegal, where it is called by the name of " sump " (in Onolof language). Its usual habitat is always far from land constantly submerged by water ; it forms woods, whose density varies from 30 to 50 trees per hectare.

The tree is very hardy and coppices well ; it bears green branches, covered with long green spines.

The wood of " sump " burns almost without smoke, and is used as fuel. It is also used for making various utensils (mortars, pestles, handles of tools, etc.)

In the region of the Senegal river flowering commences in May - June ; the fruits, formed in July, are ripe in September-October, but can still be gathered from December to February. Externally, they have a slight resemblance to the date. Their sweet deep red pulp is eaten by man and animals ; macerated in water, it gives a refreshing and slightly acidulated drink. The natives extract edible oil from the kernel, from which they also sometimes make soap.

As it is possible, beyond the needs of the natives, to procure 5000 to 6000 tons of " sump " fruit per year from Senegal, the government of this colony has made an inquiry as to the possible industrial value of this raw material.

The writer gives a complète analysis of the fruit. The kernel contains 41.80 % of fats, which is a very interesting proportion. But if the whole fruit is taken into account, the proportion of oil falls to 3.68 %, and, in proportion to the stone, not more than 7.63 %. It is therefore absolutely impossible to think of transporting the fruits or even the stones of " sump ", in order to treat them in Europe. The kernel alone might pay for its carriage, but it is difficult to extract it from its hard and elastic covering. Besides, the kernel breaks and crushes easily and would require for this reason, special precautions in packing.

The pulp can produce 9.7 to 10.8 cc., of alcohol per 100 ; the value of the alcohol would not be sufficient to be worth exporting the whole fruit.

The fruit of " sump " at present, therefore, have no interest, except for local needs in regions where the tree grows wild, and where it could be worked in a very extensive manner by the natives.

RUBBER, GUM AND RESIN PLANTS

50 – **Notes on the Cultivation and Working of *Hevea* in Cochin-China** (1). — GIRARD, E. (Administrateur-délégué des Plantations de Suzannah et Au-Lộc, Président p. i. du Syndicat des Planteurs de Caoutchouc de l'Indochine), in *Bulletin Agricole de l'Institut Scientifique de Saïgon*, Year I, No. 10, pp. 289-299. Saïgon, Oct., 1919.

GENERAL REMARKS. — The author recalls that in previous notes (2), he endeavoured to show the great advantage of intensive cultivation of Hevea with ploughing and manuring of the plantations, the importance of the task of the tappers and the relation of that task to the spacing of the trees, the different advantages of wide spaced plantations — advantages which he recommended at the time when he applied the system over very large areas; from 200 trees per ha. in his plantations of 1909, 1910 and 1911, passing to 100 in 1913, and, in 1915, he made very wide spaced plantation with coffee cultivated between the trees, 30 Hevea trees per ha. planted 18 × 18 metres (2).

The note under review is intended to persuade planters to adopt indispensable modifications in their methods of working or, at least, to commence at once experiments on the lines indicated.

WORKING. — It is generally admitted that the girths of Hevea trunks at 1 m. from the ground ought, under good conditions, to increase by 10 cm. per year, and apparently it is still held that the trees can be usefully tapped at the arbitrarily fixed size and age of 40-50 cm. girths and 5 years. This increase in girth varies generally from 2 or 3 cm. to 20 cm., according to age, spacing and many other factors which influence the growth.

It is, however, evident that the profit from tapping, always variable, is bound by various factors, components of the cost price of rubber; — market price of rubber; freight; production, taking into account the using up of the bark, for all production obtained by means

(1) This paper forms the seventh part of the general article on *Hevea in Indo-China*, published in this *Review*, Feb. 1919, No. 205, p. 183 (*Ed.*)

(2) For these questions, especially those of spacing and growing crops between the trees see *R.* Feb. 1919, No. 205, II and VI. (*Ed.*)

of excessive tapping can only be reckoned to the extent to which it compensates for all the consequences of that abnormal using up of the bark; capital invested, in relation to the possibilities of profit calculated after liberally providing for the amortisation of the plantations.

The importance of some of these factors is so great that the writer enlarges on certain points.

Relation between the production of rubber and the destruction of the bark. — The yield of rubber is directly influenced by the extent, frequency, and depth of tapping. But the surface of bark which can be worked in practice and its power of renewal are limited, while the power of elaborating latex is limited. The yield ought therefore to be kept within limits corresponding with normal tapping, so as to allow complete renewal of the bark and the preservation of the tree in full vigour. It would therefore be logical, when intensive tapping is practised, to deduct fully the amount of the enormous damage which results from the production obtained to the detriment of the capital represented by the trees thus rapidly exhausted.

Instructions for estimating the exhaustion due to intensive tapping. — Mistakes have been often made regarding the time required for renewing the bark (1).

The time required for the regrowth of the bark cut away is very variable and is longer when tapping has been intensive and was commenced when the trees were young. The fertility of the soil, spacing of the trees and care taken in cultivation, manuring, as well as correcting accidental deformations have, on the other hand, always helped and hastened renewal. Furthermore, the author thinks that it is certain that when the bark is cut away carefully and to a moderate extent, especially in the depth of the cut, it can reconstitute itself integrally in thickness, even on trees which are tapped daily. This result was obtained in 7 years in a plantation on fertile soil on trees that were well cared for, manured twice during that period and completely tapped on 1/5 of the girth in the following proportions: — On 3 notches one above the other during the first two years; on 2 notches one above the other and on a single notch during the 5 following years.

The author's experiments have shown that, for daily tapping, not deep and well done, with 2 notches on 1.5 of the girth, the average time required for complete renewal of the bark was 7 years, on fertile cultivated soil. But the author has noticed a more rapid renewal during the early years on trees tapped with one notch on $^1/_5$ of the girth for 160 to 170 days only in the year, than indicated above for trees tapped every day. Other

(1) It is usual in plantations, with all systems of tapping, to calculate the space between the cuts so that the same part is not cut a second time within 2 years in young trees and 4 years in older trees.

Tapping, as practised in plantations, is particularly well described in *La Culture de L'Hévéa, Manuel du Planteur*, by Dr. P. J. S. Cramer, translated from the Dutch and with a preface by Dr. E. de Wildeman, 1 vol. pp. 132, 40 fig., S. H. de Bussy, Rokin 60/62, Amsterdam, and A. Challamel, 17, Rue Jacob, Paris, 1911. (*Ed.*)

Hevea trees tapped from 110 to 120 days in the year, with alternate periods of tapping and rest, have shown a still more active renewal of the bark during the first year of the experiment (now in progress).

If the Hevea trees are rationally worked, but only on that condition, it should be possible to tap them for many years, working always on bark of full thickness and with entirely renewed latex vessels.

Influence of tapping on the duration of Hevea trees. — It would be unwise to fix a duration of tapping applicable in all cases, which evidently cannot be identical. But it is possible to lay down the principle that the more intensive the tapping the shorter will be the period of successful working of a plantation (it being, of course, understood that the tapping, whether moderate or intensive, is always practised in such a way as to avoid wounds and leaving beneath the bark cut away a sufficient thickness, at leat 1 mm., to assure good renewal.

The economy of bark realised by working moderately is fortunately complementary to that which is realised by avoiding the tapping of young immature trees which scarcely pays even if it does not cost more than it produces.

Too deep tapping, especially in a dry season, causes the partial drying up of the remaining laticiferous vessels, which are insufficiently protected, from which, as the result of cracks caused by the growth of the trunk, arise brown streaks sometimes assumed to be a fungous disease. They also cause swellings on the trees, with nodules on the tapped surface, which many planters assume are infections due to the tapping knife (whence the common expressions, nodular canker, and streaked canker, etc.).

Almost all deformations which check the circulation of latex and lead to drying, followed by destruction of the bark, can be avoided by careful and moderate tapping. From an economic standpoint, with intensive working, which requires a rapid amortization, plantations should be taken at their actual value at the time when tapping commences to " use them up " while there is every advantage in making them last and preserving them in full vigour.

All plantations in which trees interfere with each other before they have reached a state of development corresponding to a really remunerative tapping, should be rapidly thinned.

Plantations tapped late and moderately, yield much more rubber per ha. during the early years of working, than those where highly intensive methods are commenced at an earlier age and before the trees are completely developed. In the former case a sustained higher annual yield would be obtained and most probably the quality of the rubber would be better. At least, in similar conditions, the older the plantations are and the more vigorous and sound the bark of the trees, the higher will be their yield. For the last 10 years of the author's experiments the difference in the yield of trees tapped later and sparingly, taking an equal tapping period, may amount to over 1000 kg. of rubber per ha.

Basing his calculations on investigations made on trees of equal age, tapped after an interval of 2 years, the author found, taking rubber at 5 fr.

per kg. a difference, corresponding with the increased production noted, of 4000 fr. per ha for a period of 10 years, or 450 fr. per ha. per year in favour of the Hevea trees on which tapping began at 8 years instead of 6.

The author recommends, whenever remunerative conditions of working are realised, the tapping of trees with a density of 200 to the ha. at the age of 7 or 8 years, with a minimum girth of 60 cm and an average girth of 70 to 75 cm. at 1 m. from the ground.

The duration of profitable working, so often reduced to a few years in the case of the usual intensive tapping, could be prolonged considerably in the case of later and more moderate tapping, for the Hevea tree kept in a vigorous state can live very long, 100 years or more according to observations made in the Amazon forests.

Choice of a tapping method. — The method of tapping Hevea trees, like the fixing of the time for commencing working, should correspond with technical and financial conditions which should not be lost sight of. The author, a priori, negatives intensive tapping as its disadvantages are too great. The examination of the latex — a subject previously dealt with by M. Vernet in 1905 in his paper "*L'Hevea brasiliensis*" (No 44 of the *Bulletin économique de l'Indochine*) — should enable all planters to know that multiple tappings are excessive, as are all those which involve more than 1/5 of the girth of the tree in a single notch, if they are made daily.

The percentage of dry rubber in the latex of normal Hevea trees, which is 50 % or more when tapping is commenced — both in young and old trees — may decrease to 25 % in the case of intensive tapping. This weakening of the strength of the latex is proportional to the extent and frequency of tapping and is the cause of most of the bark diseases ; the author is convinced that this state of the latex precedes total exhaustion of the trees. Furthermore, the author is certain that the great complaint of want of uniformity in the quality, with which plantation rubber is justly charged, arises from the great variation in the strength of the latex treated, variations which must entail other modifications of very great importance in the value of the product. The quality of Para rubber depends much more on the method of tapping, reduced to 2 months a year at most for each tree and yielding, owing to this moderation, a complete latex, than to the coagulation method whose chief advantage lies in the total preservation of the constituent elements of the latex, coagulated much more by evaporation by heating than by contact with the smoke. Al these conditions which, according to the author, give Para rubber its superior quality, may henceforth be easily realised in plantations (1).

The argument of quality is added to those dealt with above in favour of moderate tapping whose practical form, ideal from all standpoints, is *alternation*, which the author, will deal with specially in detail in a forth-

(1) From the industrial standpoint, for obtaining a plantation rubber of uniform character comparable with Para, an interesting process has been recorded, the process of Maude and Crosse. See *R.*, March 1919, No. 368. (*Ed.*)

coming paper. Meanwhile he advises fortnightly or monthly alternation, the latter especially.

(1) *Fortnightly alternation.* — Two groups of trees per tapper, tapped and resting alternately for 15 consecutive days, a single notch on 1/3 of the girth on a band 60 cm. wide lasting 2 years. If this bark is cut away too soon take 90 cm. for 3 years.

(2) *Monthly alternation.* — Has the advantage of allowing Sunday rest with a yield equal to that of fortnightly alternation. This equality of yield in fewer days tapping — about 25 or 26 days out of 60 with monthly alternation, instead of 3 out of 60 with fortnightly alternation — is explained by the suppression of one of the tapping turns which causes a decrease in the yield during several days. This slowing of the flow of latex is due, in part, to its thickening and to the acidity of the healed bark.

The trees are tapped every day, except Sundays, for a month, and then completely rested for a month. As in the case of fortnightly alternation, the tapper looks after 2 groups of trees.

By giving the trees a rest of 1, 2 or sometimes 3 months according to the weather and the condition of the soil, when the leaves are being renewed, in addition to the periodical snspension rest of alternation and to stoppages caused by morning rain (2), tapping is reduced : — (1) to 105 days in the case of 3 months rest, with about 13 wet days ; (2) to 135 days if the period of rest is only one month with a similar number of wet days.

The author thinks that the strenght of the latex should never be allowed to fall below 35 %, if the bark is to be renewed properly and the trees are to remain vigorous. Ten kg of pure latex should therefore yield at least 3.500 kg. of dry rubber at the end of the selected period of alternation. Perhaps it would be advantageous for uniformity of the quality of the rubber not to reach so low a limit. Possibly, on the other hand, it would be advantageous for the yield, without causing much damage, if the strength was as low as 32 or 33 %. But it is dangerous for the health of the trees and bad for the quality of the rubber to let the strength go, even temporarily, as low as 30 %. Below this percentage diseases or signs of decay appear. Above 45 % the flow of latex is too slow to allow of a sufficient yield.

Testing the strength of latex on plantations. — Weigh a fair amount of latex, say 10 kg., quite pure, taken from any part of the lot to be tested. Coagulate this amount separately, by the method used on the plantation, weigh the rubber as it comes from the " mangle " so as to

(2) It is well known that tapping should be done before noon — for, during the afternoon the trees transpire freely and the latex does not flow well — and is not practicable on days when heavy rain falls in the morning, because the rain water running down the trunk would wash away the latex. The latex flows best when tapping is done after night rain, but it is then very thin. A well distributed rainfall throughout the year is one of the characteristics of the climate of the Malay peninsula ; wet mornings are not very important in the Malay peninsula but they may be so in other regions (Ceylon, Indo-China, etc.). Dr. Cramer's work, previously referred to, may usefully be consulted on this subject. (*Ed*).

get a approximate result. After complete drying the weight gives the yield in dry rubber. When the latex brought in to the factory is uniformly pure, this test made every day for all groups of trees — the number of groups should not be too great — should enable all essential points in the tapping to be controlled and a uniform product, in as large a quantity as possible without causing abnormal exhaustion in the trees, to be obtained. This result may be obtained while making considerable reduction in the present expenses of working by intensive tapping.

51 – **Camphor in Formosa.** — *Bulletin économique de l'Indochine*, Year XXII, New Ser., No. 136, p. 491. Hanoï-Haiphong, May-June, 1919.

The quantity of camphor coming from Formosa and exported during the year 1918 was 2 179 558 *kin* (1 307 735 kg.) representing a value of 2 942 011 *yen* (7 599 214 fr. *at par*). Compared with 1917 there was a decrease of 724 431 *kin* (434 659 kg.) and 1 686 266 *yen* (4 356 545 fr.). The cause of this decrease was the development of the celluloid industry in Japan, which uses a great part of this product.

In 1918, 1 658 177 *kin* (994 906 kg.) worth 1 757 120 *yen* (4538 641 fr.) sent to Japan an excess of 405 455 *kin* (243 273 kg.) and 743 830 *yen* (1 921 339 fr.) over 1917.

The consignments of camphor oil to Japan increased to 2 902 134 *kin* (1 741 280 kg.) worth 1 332 869 *yen* (3 442 801 fr.) a decrease of 1 080 694 *kin* (648 416 kg.) and 513 976 *yen* (1 327 605 fr.) on the preceeding year.

52 – **Varieties of Sugar Cane in Porto Rico.** — Earle, F. S. (Agronomist, Insular Experiment Station), in *The Journal of the Department of Agriculture and Labour of Porto Rico*, Vol. III, No. 2, pp. 15-25, bibliography of 9 publications. Porto Rico, April, 1919. SUGAR CROPS

The question of sugar cane varieties has attracted much attention for many years and is clearly of great importance to the planter. The number of existing varieties is very great and increases every year. There is voluminous scientific literature on the subject, so the planter has plenty of material from which to choose ; but in most regions there is a serious want of information regarding the selection of varieties to suit local conditions. A few investigators, particularly Bovell in Barbadoes and Harrison in Demerara (British Guiana), have made most interesting investigations on this subject. This work has been continued over a long series of years and is still being done ; it has served to increase very greatly the average yield of sugar cane. Unfortunately it cannot be assumed that the results obtained are universally applicable. The same painstaking experiments need to be repeated, not only in each of the cane-growing countries, but in each of the principal soil and climatic regions. A heavy yield in sugar per unit of area is what has to be looked for. Unfortunately vigour, weight of the plant and high sugar content are not always found together and some investigators even think that they are antagonistic and that high sugar content is abnormal and always accompanied by reduced vigour. It results that a higher unit yield of sugar may be obtained by a variety with a comparatively low sugar content. For example, in Demerara, the variety " D. 625 " gives a higher yield per unit than any other, and in the

Hawaian Islands almost all the sugar is obtained from " Yellow Caledonia " both these varieties are notoriously poor in sugar content.

But there are still many more factors which have to be considered in choosing a variety. With a low grade variety there is a very bulky crop and consequently, much labour is required. The choice of a high or low grade variety will therefore depend also on the local economic conditions. This discussion takes place where the planter crushes his own cane. Generally on the contrary, the miller buys his cane: he desires the highest grade varieties so that his work and expenses may be reduced, while the planter desires those which give the highest return per area unit.

In any case the greatest possible information is desirable regarding the production, requirements, and resistance to disease and pests of the diferrent varieties.

A discussion of the varieties can be made from two different standpoints: agricultural and botanical or taxonomic. Generally, it has been from the former that the matter has been regarded hitherto, and it is remarkable how few descriptions of cane varieties have been published. The principal object of the paper under review is to show that cane varieties may be described, classified and determined by the ordinary methods of descriptive botany or taxonomy. The author gives a short account of the cultivation of sugar cane in Porto Rico. He studies the different varieties of cane from the standpoint of their cultural value and their characteristics, and he describes the varieties newly grown in the country. In this way he deals with 44 varieties of sugar cane and he adds a key to these varieties.

STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS

53 - **On the Possibility of Cultivating Vanilla at Porto Rico.** — Mac Clelland, T. R., in *Porto Rico Agricultural Experiment Station, Bulletin* No. 26, pp. 1-32, 3 pl. Washington, April, 1919.

The agro-geological and climatic conditions of Porto Rico are favourable for the growth of vanilla, which grows wild in many parts of the island.

In experimental cultivation, using cuttings of *Vanilla planifolia* from the Garden at Miami (Florida), excellent results both as regards quality and yield have been obtained.

As vanilla produce is not very perishable and of small bulk, the author recommends its cultivation in localities which are not well served with roads.

In the bulletin under review the subject is dealt with mainly from technical and cultural standpoints. *Erythrina Corallodendron* makes a good support; it branches abundantly and can furnish the prunings required to form a layer of humus which is necessary for the growth of the tender fleshy roots of vanilla.

54 - **Tobacco Growing in the Central Province, Ceylon.** — Wilson, W. B., in *Tropical Agriculturist*, Vol. LIII, No. 3, p. 174-175, 4 pl. Veradeniya, Ceylon, Sept. 1919.

Tobacco growing having been tried in the valley of Dumbara (Central Province) for several years and a type of tobacco having been produced possessing qualities suitable for cigar making, the Department of Agriculture commenced, in 1918-1919, experiments at Teldeniya (Dumbara

district) in the interests of the industry. This first year's work has been devoted to fundamental trials, varied experiments and general observation.

Two experimental fields were selected and planted with the following varieties of tobacco :— (1) " Connecticut Broadleaf " (type for American cigars); (2) " Zimmer Spanish " (id.); (3) " Pensylvania Broadleaf " (id.); (4) " Halliday's Hybrid " (id.); (5) " Cuban " (type for West Indian cigars); (6) " Wilson's Hybrid " (type for American cigars); (7) " White Honduras " (type for South African cigars); (8) " Maryland Mammoth " (type for American cigarettes and pipe) (9) " Dumbara " (local type for cigars); (10) " Natal Selections " (type for South African cigars); (11) " Ohio Hybrid " (Cross between types for West Indian and Indian cigars). The seed was sown in well prepared nurseries in January and February, 1919 and, except those of the Cuba variety (No 25. in the list), of which only a small portion germinated, and Sumatra seed, also sown, which did not germinate at all, the seed produced a sufficient number of plants of each kind. These plants were transplanted at the beginning of April. In April and May the weather was exceptionally favourable ; but considerable damage was caused by the " split worm " or " Potato Tuber Moth " (1) and, later, during the dry period in June, by green fly. Other insect pests were not numerous and were easily dealt with.

The growth and the appearance of the tobacco were satisfactory and the following remarks were made :—

" Connecticut Broadleaf ", " Pensylvania Broadleaf " and " Halliday's Hybrid " did particularly well and looked very vigorous ; of these three varieties the first did best ; the third bore leaves inclined to be very dark coloured. " Zimmer Spanish " produced well, but gave somewhat coarse leaves.

Of the " Cuban " variety only a small number of plants resulted at germination and these plants did not grow well.

" Wilson's Hybrid " proved insufficiently hardy. " White Honduras " grew well, but produced very thick leaves, which makes moist conditions and modification in the method of culture desirable for this variety.

" Maryland Mammoth " is very late and dry weather towards the end of the season might cause uneven results.

The Dumbara variety grows without trouble and produces leaves of good texture, but, having a bare petiole it yields a low percentage when the petiole is taken away, and, for this reason it is not recommended.

" Ohio Hybrid " is particularly liable to attack by green fly and does not do well. It is, however, a type of very superior quality and it ought to be further experimented with.

55 – **Possibilities of Cinchona Cultivation in Indo-China.** — CAPUS, in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 10, pp. 310-311, Saïgon, Oct., 1919.

Paper by M. CAPUS, Délégué du Gouvernement général de l'Indochine,

(1) Splitworm = *Phthorimaea operculella* Zell. Cf. *R.*, March, 1919, No. 404. (*Ed.*)

written under this title and from which the *Bull. agr. de l'Inst. Scient. de Saïgon* has abstracted the following information: —

The author recalls experiments undertaken 30 years ago by ALANSA at Mount Bavi in upper Tonkin, germinations obtained at the botanical garden at Saigon, then the more recent experiments of Dr. YERSIN in the mountains of Suôi-Giav (Annam).

The *Cinchonas* grow in America at altitudes between 700 and 2900 m. In Java and the Nilghiris, the first successes were obtained at 2600 m. altitude (minimum temperature 9,8° C,, maximum 20,5°C.), then at Noddivvatum, alt. 600 m. (minimum temperature, 12°, max, 18.8°, C.) (1).

In Ceylon, in the district of Dimbula (minimum temperature 6.90 max, 31.7°, average 18.8° C.) cultivation of cinchona has been undertaken.

M. PRUDHOMME (Directeur du Jardin colonial, Nogent-sur-Marne, France) thinks that the optimum conditions for the growth of cinchona from the standpoint of temperature are the following:— min. 4°, max. 33°, average of the minima 15°, average of the maxima 27°, general average 21°. C (2).. It is admitted in Java that the cultivation of cinchona is not satisfactory below 700 m. in altitude.

The species *C. Calisaya* and *Ledgeriana* are more sensitive to cold than the species *C. officinalis* and *succirubra*. For the two latter the temperature ought not to fall for any length of time, or often, below freezing-point.

Cinchonas require a fairly high degree of moisture in the air. Rain ought to be as frequent as possible, interrupted by dry periods.

The cinchonas are not exacting from an agrologic standpoint. They require a friable soil in which water does not stagnate.

The author thinks, by comparison, that the cultivation of cinchonas could be tried in Indo-Chinani the high vallies of Da-lagna and Don-naï and in the Annamitic Range up to the plateau of Tran-ninh, mentioning specially the plateaux of Lang-biang, Darlac, Bolowens, and Tran-ninh, situated at altitudes varying between 1000 and 1800 m. The Elephant Range in Cambodia may also be worth attention.

56 – **Cultivation of Ipecacuanha, and its Possibilities in Indo-China.** — CHEVALIER, AUG. and LAHILLE A., in *Bulletin agricole de l'Institut scientifique de Saïgon*, Year I, No. 8, pp. 225-231, Saïgon, Aug., 1919.

There are several species of true ipecacuanhas ; false ipecacuanhas, not containin emetin, are also known. The true ipecacuanhas belong to the family of Rubiaceoe, tribe of the Psychotriae, genus *Uragoga* L. = *Cephaelis* Gaertn. = *Pyschotria* L. The species usually cultivated are *Uragoga Ipecacuanha* (L) Bn = *Cephaëlis Ipecacuanha* Rich. = *Psycho-*

(1) Regarding " La culture de quinquina à Java " see the original article by Dr. J. VAN BREDADE HAAN (Inspecteur de l'Agriculture indigène, at Buitenzorg, Java), published in *R.*, Nov., 1915 pp. (*Ed.*)

(2) This information is taken from M. PRUDHOMME'S book, then director of agriculture in Madagascar, entitled " *Le Quinquina* " (Culture, preparation, commerce), p. 16. (Challamel, Edit., 17 rue Jacob, Paris, 1902). This book includes an appendix on cinchona in Madagascar, pp. 69-80. Regarding the introduction of cinchona into Madagascar see the article by M. J. LEGENDRE summarised in *R.*, Nov. 1918 No. 1247. (*Ed.*)

tria Ipecacuanha Stocks, indigenous in Brazil, where the roots are obtained for exportation (the lesser annulated ipecacuanha). Another species from the equator is *Uragoga granatensis* H. B. (the greater annulated ipecacuanha),

There are several species of *Uragoga* growing in the virgin forests (shady and fresh parts) of Cochin-China and Annam, but no research has yet been made to ascertain whether their roots also contain the precious emetin.

The cultivation of ipecacuanha, outside the countries where this plant is found in a wild state, has been tried in several tropical regions, but its success appears very doubtful.

Several plantations of ipecacuanha have existed, for some years, in the Federated Malay States, and one kind is even known in commerce under the name of " Ipecacuanha of Tohore. "

The cultivation of ipecacuanha having been developed in these States, the authors advise its trial in certain regions of Cochin-China or of South Annam, under the best experimental conditions The attempt is worth undertaking, because of the continued high price of ipecacuanha.

57 – ***Ilex vomitoria* as a Source of Caffein.** — POWER, F. B. and CHESNUT, V. K., in *Journal of the American Chemical Society*, Vol. XLI, No. 8, pp. 1307-1312. Easton, Pa., August, 1919.

In the Southeastern States of North America there is a native shrub, *Ilex vomitoria*, whose leaves contain sufficient of caffein (from 0.3 to 1.67 % of air dried material in the various samples examined by the authors) for the plant to be used as raw material for the extraction of the alkaloid.

Up to the present, caffein has not been found in any other North American species of *Ilex*, or in the European holly, *Ilex aquifolium*.

" Paraguay tea " or yerba maté is obtained from a South American species, *Ilex paraguayensis*.

58 – **Fruit Trees in Tonkin.** — RETIF, in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 9, p. 295, Saïgon, Sept., 1919. ARBORICULTURE

With reference to the paper by M. AUG. CHEVALIER on " Fruit-trees in Indo-China " (1), the author has sent M. CHEVALIER a note containing new data on the question.

He has seen in the region of Langson, among the Thos, plum-trees, pear-trees and peach-trees, all bearing good fruit when it is allowed to ripen. He also saw cherry trees, of which several measured 30 cm. in diameter. There are large numbers of these trees in the Maoson, at 10 km. from Langson. In the forests of this region, chestnut-trees, pear-trees, etc., are also found.

On the other hand, vines are scattered over the region of Langson. The author has noticed, in the Maoson, vines as thick as an arm, climbing like creepers, and which yield fine bunches of red, sweet, grapes. The Maus sell them during the season in the Langson market. The author

(1) See *R.*, July-Sept, 1919. No. 908. (*Ed.*)

made a barrel of 200 litres of light red wine in 1918, and obtained brandy by distilling the residues and the lees.

59 – **On the Sugar Contents of Cider Apples.** — TRUELLE, A. in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. V, No. 28, pp. 738-740. Paris, July 30, 1919.

The practical object of this paper is to show cider makers who wish to buy apples to make them into cider or brandy, whether there is advantage in selecting fruit from trees cultivated on hillsides, or plateaux, or from those borne on trees grown in vallies.

The analytical results refer partly to research carried out during 10 years, on a dozen varieties belonging to three seasons or ripenings. However this note nominally concerns only 6 varieties, which are the object of considerable trade in the Auge district: — *1st season:* — Girard — *2nd season:* Cimitière de Blangy, red Fréquin — *3rd season:* Bédan, Binet, Bouteille.

The following, in summary form, is the special information which the author has deduced from chemical analysis, because it presents practical interest, both for the purchase of apples, and the manufacture of cider and brandy: —

(1) The situation of the land, apart from its chemical composition, age of the apple trees with which it is planted, and the surrounding weather conditions, seems, according to whether it is on hillsides, weather plateaux, or in vallies, to exercise an influence on the production of sugar in certain varieties of cider apples.

(2) In the above-mentioned conditions, among the same varieties, cultivated on hillsides and in vallies, the influence of these situations makes itself felt very diversely with regard to the sugar content: sometimes it is the hill side which is best, sometimes it is the valley, sometimes neither is good. Thus of the 6 varieties studied here, Cimitière, Bedan, and Bouteille respond to the influence of the hills, Girard and Binet to that of the vallies and red Fréquin remained unaffected. It is possible, considering results obtained from 6 other varieties, of which the analyses have not been given in this note, to classify Aufriche, Citron, Marin-Onfroy, Peau de Vache with the former, and Gros Matois and red Joly with the latter.

(3) The differences between the extreme degrees in the scale of density and the corresponding weights of sugar, which exist in the various juices of the same variety, have a wide range, but if only the average of the sugar in these juices, taken as a whole, for each kind of ground, are compared one with another these differences become very slight.

(4) The situation of the ground on hillsides, plateaux or in vallies only appears to have, under the conditions indicated, a generally slight influence on the production of sugar in the varieties of cider apples. Again, for the buyer who, only wishing to make ordinary ciders or brandy, in the first place requires a high total sugar content, the situation of the orchards has only relative importance, and comes after the nature of the variety, which, on this point, comes before the composition of the soil.

It would be quite different if it was a question of the preparation of high grade ciders, because, besides sugar, there are all the other constituent principles of the juice, which, according to their proportion, play a considerable role, both from the standpoint of the preservation of the ciders made, and of the elaboration of the different peculiarities of their taste, which the soil, according to its very distinct composition, very often modifies more or less agreeably to the palate. Also, to obtain more finely fruited and lasting ciders, the author would give the preference to apples coming from the hills, over those picked in the vallies, varieties being identical.

60 – **Use of Sulphur in Viticulture.** — CHAUZIT J., (Communicated M. VERMOREL) in *Comptes rendus des séances de l'Académie d'Agriculture de France* (French National Society of Agriculture) I, Year 1914, No. 2, pp. 48-51, Paris, Jan. 14, 1914. — II, Vol. V, No. 52, pp. 835-837. Paris, Oct. 22, 1919. VITICULTURE

I. — According to the experiments *in vitro* of MM. BOULLANGER and DUJARDIN (1), according to the experiments in pots of MM. VERMOREL and DANTONY (2), and according to his own large-scale, experiments the author believes it possible to state : —

(1) That the greater the quantity of organic matter available in the soil, the greater is the effect of sulphur ; when the quantity of organic matter decreases, the effect of the sulphur diminishes, becoming almost negligible when there is no organic matter.

(2) That when sulphur is incorporated with the organic mass on which it is intended to act, its effect is more clearly noticeable.

(3) That the yield increases according as the proportion of sulphur used is greater.

II. In the new experiments, the principle of the conclusions of 1914 is confirmed. Whether the sulphur is applied to a vine that has not been manured for 2 years, or whether it is used on a vine which was manured with stable manure, the author has noted, in both cases, important increases of the crop.

The amount of sulphur used was 200 kg. per hectare.

In the experiments of MM. VERMOREL and DANTONY, pyrites were used, whereas in those of the writer sulphur was used. M. HALLER, present at the meeting of the Academy, observed that in the case of pyrites, these oxidise, and give sulphate of iron ; sulphuric acid, produced from this sulphate, fixes ammonia, and prevents loss. The question was therefore, according to him, whether the sulphur oxidised ; it would also, in that case, have the effect of fixing the ammonia, and the result would be the same. This is a possible chemical explanation of the phenomena observed.

61 – **The Forests of the Grand Duchy of Luxembourg.** — *Journal de la Société Nationale des Agriculteurs de Belgique*, Year I, No. 12, p. 157, Brussels, August. 2, 1919. FORESTRY

One third of the total area of the Grand Duchy of Luxembourg, 80,00 ha., is covered with forests, including 20,000 ha. of coppice for bark, 50,000

(1) See *R.* Oct. 1912, No. 1397. — (2) See *R.* Jan. 1914, No. 18. (*Ed.*)

ha. of high forest of beech, treated under the selection method, and 10,000 ha. of conifers. The State owns only 2000 ha., communes and public institutions 30,000 ha., and the rest, which includes almost all the coppice for bark, belongs to private persons.

The coppice for bark, almost valueless before the war, has given enormous revenues during the war, tanning having attained unusual prices.

Among the coniferous species the Scots pine predominates on dry sandy soils, whilst spruce prevails on the best soils. The pit props, which conifers furnish, are almost exclusively exported to Belgium, in spite of the import duty imposed upon them at the frontier. The small quantity of sawn coniferous timber is sold in the country itself.

The greater part of the Luxembourg forests is composed of beech, mixed with oak, and treated as high forest, under the selection method. Beech, for lack of demand as timber, is almost entirely sold as fire wood, and consumed in the country. During the war, it is true, large beech logs sold at very high prices. Oak, which forms only 5 to 10 % of the total, is sawn up in the local raw-mills. Pit props of this timber are bought by the mining companies of the country.

The 30,000 ha. of woods belonging to the communes are under the forest law, and divided into 4 districts. The communal woods, almost exclusively composed of high forest of beech, treated under the selection method, with 10 % of conifers, are the finest in the Grand Duchy

62 – **Forest and Timber of the Adana Vilayet, Turkey.** — Egyptian Expeditionary Force, Intelligence Branch, in *The Board of Trade Journal*, Vol. CIII, No. 1188 pp. 304-305. London, Sept. 4, 1919.

The forests of the Taurus, Anti-Taurus, and Amanus mountains, within the boundaries of the Vilayet of Adana, are, in comparison to the area involved, among the most important in the world. Their importance is due to four causes : —

(1) Their situation as regards markets.

(2) The quality of the timber.

(3) The practically unlimited water power in the province for working sawmills and electric transporters.

(4) The large permanent rivers flowing through the principal forests, affording a simple and cheap means of transport for lumber to the railway or the sea.

For many years these forests have been devastated by uncontrolled cutting and forest fires. These latter were occasionally accidental but usually they were lit intentionally by nomadic tribes from Aidin. Moreover, though all forest lands are State owned, till quite recently no attempt at re-afforestation was made.

The total of so-called " forest lands " is about four million acres but the area of timber forests (i. e., whose timber is of commercial value as timber) is 4 206 550 donums, which represents a little under one million acres (one acre equals 4.4024 donums). The following list shows the percentage of the different species of trees found in the forest. The figures

are only approximate, but must suffice, as no more exact information is procurable :—

Pine (5 varieties)	40 %	White Cedar	10 %
Oak (3 varieties)	17	Spruce (3 varieties)	5
Mulberry, Alder, Caroub, Willow, Holly, Ilex		Wild Olive	3
		Birch	2.5
		Wild Cypress	2.3
		Juniper	1.5
		Plane	1.3
		Box (2 varieties)	6
Arbutus, Walnut, Bay, Poplar, Berries, Other small trees	16	Beech	5
		Yew	3

The Ak Tcham, or white pine, is the most valuable tree in the province. It resemble the Swedish Pitch Pine, but is finer in the grain, easier to work, and more durable. It is not found at an altitude of less than 4 000 feet. This tree is 100-120 feet in height, absolutely symmetrical, and the same size almost the whole way up. It is 3-5 feet in diameter and the only branches are at the top. It is believed that there is no tree in Europe to equal it for size, quality, and symmetry.

The Karra Tcham, or black pine, resembles the Norwegian Pitch Pine but is harder, coarser, and more resinous. It is used for sleepers and roof timbers. The other varieties of pine, though of little commercial value as timber, are very resinous and give such by-products as pitch, Stockholm tar, resin, turpentine, and wood alcohol. These trees grow on the lower slopes of the mountains.

The white cedar grows at an altitude of 4 000-6 000 feet. It is an excellent timber for cabinet-making, and will never rot. The spruces (*Picea excelsior, Picea orientalis,* and *Abies cilicia*) are all of value for making wood-pulp for paper.

The large forests of wild olives could be properly grafted and made the source of substantial revenues.

The mulberry is indigenous to the country. The silk industry in the Vilaget was renowned, but in 1900 the Turkish Government imposed such high taxes on the mulberry trees that the industry has now entirely disappeared. The yearly silk output was 10 000 okes, *i. e.*, 28 320 lb. (1 oke equals 2832 lb.).

The total quantity of timber (of commercial value) in the forests is slightly over 50 million cubic metres, *i. e.*, 1 750 million cubic feet. During the war the Turks used 250 000 tons, *i. e.*, about $^3/_4$ million cubic metres, of Cilician timber for fuel on the railways.

63 – **The Lumber Trade of Bolivia.** — HAZELTINE, C., in *Commerce Reports*, No. 187, p. 820. Washington, D. C., Aug. 11, 1919.

Although Bolivia produces an infinite variety of valuable cabinet

woods, such as walnut, cedar, mahogany, ebony, and laurel, the lack of internal transportation facilities makes it necessary to import large quantities of construction lumber. Bolivia's lumber imports in 1914 aggregated 23 631 metric tons and were valued at $453 418. Chile and Argentina supplied the 6 tons of this which were classed as cabinet woods; 5 773 metric tons of railway ties, valued at $230 906 were imported, chiefly from Chile; and of the 17 852 tons of other lumber the United States supplied 15 213 tons (chiefly Douglas fir), valued at $187 178.

64 – **Scots Pine of Belgian Origin.** — POSKIN, A. (Professor at the State Agricultural Institute of Gembloux), in *Bulletin de la Société Centrale Forestière de Belgique*, Year XXVI, Vol 4, pp. 139-154, and Vol. 5, pp. 203-222. Brussels, July 15 and Aug. 15, 1919.

Notes on Scots Pine collected in Belgium since 1912 This tree, so common in Belgium, is not only interesting on account of its timber but also on account of the large crop of seeds which it produces in Lower Belgium. The author, in the first place, states that the seed of Scots Pine of Belgian origin is not inferior in quality to that produced elsewhere, and he considers that the following basis might apparently be adopted in the utilisation and sale of these seeds :—

(1) The Scots Pine of Lower Belgium is well suited to the local conditions and succeds well there. It can also be grown in Middle Belgium. In the Ardennes we are less well informed regarding the variety which is most suitable. The pine of the lowlands has so far done well in experimental planting, on a small scale, carried out up to an altitude of about 400 m. The value of the seed gathered on the spot is not yet sufficiently known to enable it to be used with confidence when taken from good stands; besides, the greater part of the pine woods is formed with seed of Campine or foreign origin. This point requires close investigation, for the Scots Pine has been largely planted and there are complaints of its premature decay in certain places, especially in the Middle Ardennes.

(2) It is desirable that seedsmen should organise themselves methodically and give information in their catalogues regarding the purity, germinative faculty (already done, but very imperfectly), so that a judicious and well founded choice may be made. Since in the present state of information, the seed of stunted Scots pines is not to be trusted, it would be well if seedsmen commenced by selling, under guarantee, seed from good parent trees. It would be well to cary out intensive research regarding the origin of the seed of Scots Pine.

(3) Commercial seed too often has insufficient germinating power; the bad quality is due either to unfavourable conditions of origin, or to defective or prolonged keeping. There is every reason to use as good seed as possible, as the yield of plants is then proportionately greater. Germinative power for Scots Pine ought not to be less than 75-80 %; that is for seed of at least 1 year old, according to the author's tests.

(4) It would be well for the purchaser to stipulate in all selling contracts, for most forest seeds, a minimum purity and germinative power, quality guaranteed by the seller and controlled by a seed-testing station.

This method might be still further improved with the object of obtaining as perfect seed as possible. — The minimum power of germination required for Scots Pine is, for example, 80 % (often it is less ; the parties in the matter dare not fix it too high). In this case the seller has nothing to gain by supplying seed of greater power of germination. Would it not be more rational, while requiring a minimum quality and making an analysis after delivery, to fix the price of the seed according to the percentage of cultural value indicated by the testing station, as is commonly done in the chemical manure trade ? — It would be agreed, for example, to pay at a unit rate of 0.10 fr. If the cultural value recorded by the testing station is 85 % the seed would be worth 8.50fr. per kg.: the seedsman and the buyer would thus both benefit, the former by delivering and the latter by using, first quality seed.

(5) Partnership ought, apparently, to give good results in the matter of forest seeds.

The State would act wisely, it seems, by centralising, through the agency of its Forest Administration, the orders for the principal seeds required for the State nurseries and afforestation. It might perhaps help the Communes and public Institutions by supplying certain seeds. Nursery gardeners and private land-owners would also find it very advantageous to combine for purchasing seed, through special forestry societies or agricultural co-operative societies, of which a good number already exist in Belgium, combining their orders for various products such as manures, seeds machinery, etc. Such combination would have a healthy influence in extending and facilitating the practice of analysis, in obtaining favourable charges from testing stations, and in requiring real guarantees regarding the origin and quality of the goods.

65 – **Effect of Grazing upon Forest Reproduction.** — I. Sparhawk, W. K. N. (Forest Examiner), Effect of grazing upon Western Yellow Pine Reproduction in Central Idaho. in *United States Department of Agriculture, Bulletin No. 738 ,Contribution from the Forest Service*, pp. 31, pl. 4. Washington, D. C. 1918. — II. Sampson A. W.)Plant Ecologist), Effect of Grazing upon Aspen Reproduction. *Ibid.*, No. 741. pp. 29, fig. 7, pl. V, 1919.

The regulation and control of grazing is of far-reaching importance in the organisation of absolute forest land for the continuous production of crops of timber. Too often in the past the United States has sacrificed reproduction in order to placate the cattle and sheep men, sacrificing thus reproduction at the most opportune time for obtaining it, and now it can only be secured by planting, often at prohibitive costs.

Throughout most of the western United States grazing on absolute forest land is of vast economic importance, and the forester accepts the general principles that grazing must be carried on as a part of forestry management.

He does not object so much to grazing as he does to unregulated grazing. In many parts of the westernUnited States the present economic importance of grazing so overshadows the importance of the forest for the production of timber that there is grave danger in overgrazing much of the

absolute forest land, which will lead to a gradual destruction of the timber now standing and more or less complete elimination of reproduction following fires and lumbering.

One of the most important problems dealing with large areas of the absolute forest land is how intensively can it be grazed without serious injury to it as a forest. The many researches conducted by the United States Forest Service and by other agencies in recent years have thrown much light on grazing problems in relation to natural reproduction (1).

I. — A recent study was made by the U. S. Forest Service of the effect of sheep grazing on a number of sample plots on three grazing allotments between 1912 and 1914 in the National Forest of Central Idaho. Sheep injure forest reproduction by browsing and by trampling. Slight browsing of the needles, of side branches, of the leader, or of the bark does practically no damage to the tree, though when repeated it may result in stunted growth or the death of the tree. Severe browsing, as occurs around bed grounds, often kills the seedlings. Trampling usually is not serious. Damage to seedlings more than a year old is negligible: while as high as 100 per cent — an average of about 20 per cent. for all plots — were killed when less than one year old. Western yellow pine (*Pinus ponderosa*) is injured the most by browsing, lodgepole pine (*P. contorta*) less so, and Douglas fir (*Pseudotsuga taxifolia*) least. White fir (*Abies concolor*) is practically never browsed. Of 1782 seedlings killed, 73 % were less than a year old, and but 5 % were over 6 inches in height.

Injuries which did not result in death were greater late in the season than during the earlier period, due to drying of the forage as the season advanced. Those killed by grazing were greater earlier in the season than later, as the stem breaks more readily when succulent than after lignification has set in. Injury and death increased fairly constantly with increased intensity of grazing, though after a seedling's third year less than 1 per cent. per year, of the trees is killed by grazing of moderate intensity. More than three times as many seedlings are killed by other causes than sheep. Drought, winter-killing, rodents and birds, and fungous diseases, were the chief causes of death, while frost, rodents and birds are responsible for minor injuries. The benefits of sheep grazing to the forest are through the reduction of fire by the destruction of the inflammable material and the aid to natural forest reproduction, which is often overestimated.

II. — Another study of the United States Forest Service deals entirely with the effect of grazing upon aspen reproduction. This study was conducted in the Monti National Forest, in Central Utah, and clearly shows that great damage to the natural regeneration of this species results from both sheep and cattle grazing, although the regeneration usually appears in dense stands and is almost entirely from root suckers. There is little or no aspen reproduction until the stands are severely opened up by lumbering or fire. Fully stocked reproduction is best after clear-cutting. The author's studies appear to show that even where sheep in moderate numbers

(1) See *R.*, 1918, No. 1365. (*Ed.*)

are permitted to graze on such clearcut areas the aspen reproduction is often destroyed, almost, to the last sprout. The damage done by sheep is much greater than by cattle, and the damage by both depends upon the duration and intensity of the grazing.

The experiments extended over a period of five years, and sample plots were established on clear-cut areas, which were studied each year and records made of the reproduction. Some of the plots were lightly grazed, others moderately grazed, and still others heavily grazed. The amount of damage on all plots varied somewhat with the season. The mortality of one-year-old sprouts, even under light grazing, is so high it is reasonably sure to have a determined effect on the stand of timber. If the sprouts that appear the first year after clear-cutting are destroyed by grazing, the sprouts, the succeeding year, are much less vigorous. Those produced the third season and later are distinctly lacking in vigour and are of little value for regeneration. Aspen sprouts grow rapidily, and at the end of three years they attain a height which exempts them from destructive grazing by sheep, and after four or five years are damaged little by cattle. The problem, therefore, seems to be the protection of reproduction for a period of three of five years after clear-cutting, or at least to protect it adequately to assure reproduction in fully stocked stands. Although the author believes that very light grazing by sheep may do little harm, he does not believe it practical to attempt sheep grazing for a period of three years after clear-cutting. He is of the opinion, however, that the moderate grazing of cattle will still permit a sufficient number of sprouts to survive to form a fully stocked stand. It appears to be necessary in order to obtain an aspen reproduction either to exclude stock altogether for a period of three years, or in the sheep country to shift from sheep to cattle for a three-year period when sheep can again be safely grazed. Where the aspen is not in a cattle country the only necessity in order to obtain reproduction is to control the grazing and properly distribute the stock by means of drift and division fences.

The bulletins under review are additional evidence of the great injury to forest reproduction on absolute forest land by uncontrolled and unregulated grazing. The accumulated evidence of the past decade should force every thoughtful man to the realisation that grazing is a serious menace to the natural reproduction of forests. The first duty of the forester is reproduction. Upon him falls the responsibility for successful crops of timber on absolute forest land under his control. It is his duty, therefore, and not of the stockman, to determine when and where stock should be grazed and when they should be excluded from given stands. It should be his province to decide the grazing possible within the limits of good forestry. The pressure for grazing areas in the western United States must not force grazing beyond the limits of the forest, thus causing its detriment and possible destruction (1).

(1) See *Journal of Forestry*, Vol. XVII, No. 5, pp. 564-566, 1919. (*Ed.*)

66 – **Method of Working Bamboos.** — MARSDEN, E. (Silviculturist, Forest Research Institute, Dehra Dun), in *The Indian Forester*. Vol.XLIV. No 4. pp. 147-165. Allahabad, 1918.

In 1910, experimental plots were laid out to ascertain the best system of working *Dendrocalamus strictus* bamboos, and these have been examined in detail annually. The methods under experiment have been: —

(1) *Rotation*: *a*) Cutting the bamboos annually; *b*) cutting the bamboos every second year; *c*) cutting the bamboos every third year; *d*) cutting the bamboos every fourth year.

(2) *Proportion of bamboos cut in the 1 and 2 year rotation clumps*: *a*) cutting all bamboos except the new shoots of the current year, *b*) cutting of half the bamboos except the new shoots of the current year.

(3) *Height of cutting*: *a*) cutting the bamboos above the first node i. e. close to the ground; *b*) above the third node; *c*) above the fifth node.

Two localities were selected for these experiments, in the United Provinces of India, one dry and the other comparatively damp. In one of these localities three clumps of bamboo and in another, five clumps separated from each other and distributed over the plot, were subjected to each variation of experiment.

In recent years, before the experiment was begun, the bamboos in these two localities had been worked under a three year rotation, all culms, except the shoots of the current year, being cut regularly. Thus, at the time the experiment started, no culms were more than two rains old. Before beginning work on the experimental plots, all clumps were thinned of dead or imperfectly developed culms.

The following show the results of the experiment with *Dendrocalamus strictus* in the United Provinces of India only;—

1) Annual working, whether cutting high or low, whether removing all old culms or leaving half of them, leads to more or less rapid reduction in the size of the clumps, in the number of new shoots, and in the girth of culms.

2) When all the culms except those of the current year are cut, the clump deteriorates. This is true for 1 year, 2 and 3 year rotations, and for cutting at the height of one node, three or five nodes. When the rotation is 4 years this result is less obvious.

(3) When the rotation is one year and only half the number of old culms is cut, the results are better than when all old culms are cut. The height at cutting makes no difference. Of 15 clumps treated thus, two only were in good condition; this method cannot then be recommeded. If only half the old culms were cut, the clumps under a 2 year rotation were in much better condition than those under 1 year rotation.

(4) Whatever the rotation, a certain number of old culms should be left for two reasons: *a*) for the mechanical support of new shoots; *b*) to maintain the rhizomes in full vigour.

(5) The effect of difference in height of cutting upon the health of the

clump is negligible. Cutting too high produces a number of twigs at the top of the stumps, which impedes working.

The production of new shoots is not affected by the height of cutting the culms. But removing half the old culms gives more shoots than clear-felling all old culms, and 2-year rotation more than 1-year rotation. Of the methods under experiment, most new shoots were yielded by the clumps worked under a 2-year rotation, when half the number of old culms were felled.

Felling all the old culms fails to produce many new shoots, even when the rotation is four years. It is, however, probable that a 3-year rotation, some of the old culms being left standing, would give better results than a 2-year rotation.

Clear-felling all culms including those of the current year, nearly, but not quite, kills the clumps. After four rains, the clumps are beginning to look up again, and shoots about $^3/_4$ inch thick begin to arise. Repeating the complete cutting of all culms for two consecutive years would probably here kill most clumps.

To work economically, it would appear that in each clump some old culms should be left standing a 2-year rotation, leaving half the old culms standing may be better than a 3-year felling of all the old culms, but a 3-year rotation leaving some few old culms would perhaps be still better.

A system of working bamboos may be based on the size of the clump, on the number of new shoots produced, or on the minimum number of old culms to be left standing. In every case the system chosen must be one which admits of easy check. If a certain proportion of the old culms is laid down as the standard, it is in practice difficult to check whether too many culms have been felled or not. Similarly, any rule prescribing a minimum number of old culms to be left standing based on the number of new shoots is equally impracticable.

It would be simpler to fix a minimum number of old sound culms at least 1 inch thick, which must be left in each clump. But the size of clumps varies, so the average size of clumps in the locality must be ascertained. If each average clump contains 20 old culms, and the rotation is 3-years, a minimum of seven old culms per culm might be fixed.

Another problem is the distribution within the clump of the culms left standing. Clear-felling part of the clump is liable to kill that part; the culms left standing should therefore be distributed evenly over the clump.

While a fully-stocked clump produces more shoots than a severely worked clump, there seems ground for belief that where kept in an open condition, more shoots will arise than if allowed to become congested. Loosening the earth and heaping it up round the base of the bamboo clump is likely to stimulate the sprouting of new buds. When the bamboos have been worked continuously for years, it might be highly beneficial to give the clumps a rest for 3 to 4 years before introducing the new method of treatment.

LIVE STOCK AND BREEDING.

HYGIENE

67 – **Poisoning of Calves by *Iris*, Observed at Abbotsford, British Colombia, Canada.** — BRUCE, E. A., in *Journal of the American Veterinary Medical Association*; Vol. LVI *v. LVI, New Series*, Vol. 9, No. 2, pp. 72 74. Baton Rouge, Oct., 1919.

LINNAEUS had previously observed that Irises are poisonous to cattle, but cases of poisoning by these plants are rare. Some cases of human deaths caused by eating the rhizomes of *Iris versicolor* in mistake for those of *Acorus Calamus* and several other species considered poisonous because they contain bitter resins and iridine, a purgative glucoside, have been noted. The author has noted 3 cases of poisoning of calves of 3, 4 and 4 1/4 months respectively, which, being shut up in an enclosure, ate the rhizomes of a species of Iris which chanced to lie on the ground ; two of them died before the second day and the third succumbed on the 4th day. The principal symptoms were :— profuse salivation ; inflammation and hardening of the ganglions of the head and neck ; appearance of ulcers on the lips and muzzle ; acute pain in the belly ; faeces tinged with blood shortly before death. Post mortem examination showed — irritation of the 3rd and 4th stomachs ; black spots on the intestines ; kidneys, liver and spleen very dark in colour.

68 – **Treatment of Horse Mange by Chloropicrin Fumes** (1). — BERTRAND and DASSONVILLE, in *Comptes rendus de l'Académie des Sciences*, Vol. 169, No. 10, pp. 486-489. Paris, Sept., 1919.

The energetic insecticidal action of chloropicrin having been already reported by the authors, (1) they whished to try it in the treatment of horse mange. The horses were shut up in closed boxes, from which only their heads emerged through an opening, a canvas collar holding the head of the animal. In the boxes 20 gm. of chloropicrin per cubic m. were projected, by means of a syringe, furnished with a vaporising nozzle, avoiding direct

(1) See *R.*, July-Sept. 1919, No. 1050, and No. 6, of this *Review*. The experiments of the authors confirm the results of research, previously carried out by Mr. W. MOORE, who has stated in a former paper (*Journal of Lab. and Clinical Medicine*, Vol. III, No. 5, pp. 261-268, 1918) that thecompound in question is efficient as a fumigant against lice in clothes, into which it penetrates completely, killing all the adults in the space of 15 minutes, and their eggs in the space of half-an-hour ; the destruction of insects takes place all the quicker, if the temperature of the fumigating room is higher. In another paper (*Journal of Economic Entomology*, Vol. XI No. 4, pp. 357-362, 1918) Mr. MOORE has described some tests carried out by himself at the Agronomic Station of Minnesota, with the following results : — Chloropicrin using 8 to 16 g per cubic m. destroys insects which carbon disulphide could destroy using 48 to 58 gm. per cubic m. In the disinfection of seeds, it is true that chloropicrin is more likely to injure the germinative faculty than carbon disulphide, but if normal quantities are used, if the seeds are dry, and if care is taken to ventilate well after fumigation, the seeds would keep their physiological soundness. Chloropicrin penetrates, in 24 hours, through sacks of flour of 23 kg. at a temperature of 20° C, killing all insects infesting the flour; it was noticed, on the other hand, that this insecticide slightly diminishes the bread-making value of the flour. Chloropicrin free from impurities (chloride and peroxide of nitrogen) does not damage cloth, and does not affect colour (*Ed.*)

projection of the liquid (very irritating) on to the animals. The animals remain in the box for half-an-hour. The head of the horse is coated with an ointment composed of 2.5 gm. of chloropicrin to 100 gm. of vaseline. The vapour bath is repeated a second time at the end of 2 or 3 weeks. The results were enterely satisfactory.

Compared with the treatment of mange by sulphur dioxide fumes, treatment by chloropicrin fumes has the advantage of being: — more rapid (30 minutes instead of 2 hours) ; easier (there is no sensible increase in the atmospheric pressure inside the boxes, which does away with the necessity for absolute airtightness ; besides the new method has no destructive effect on the material of the collars, requires no special vaporiser etc) ; is surer ; and less dangerous for the animals.

69 – **Period of Incubation of the Eggs of *Haematopinus asini*** — Bacot, A. and Linzell L., in *Parasitology*, Vol. 11, No. 3 and 4, pp. 388-392. Cambridge, Oct., 1919.

Three kinds of lice are found on horses ; two Mallophaga (*Trichodectes equi* and *T. pilosus*) and one Siphunculata or blood sucking louse (*Haematopinus asini*); this last is much more common than the others and also it causes greater irritation. In badly infected cases it causes constitutional disturbances and emaciation ; possibly, like many other blood-sucking insects, it is a carrier of disease, although hitherto no disease can be definitely attributed to it ; lastly it is very difficult to destroy.

The authers, therefore, thought it desirable to study the development of the eggs of this parasite at the Central Veterinary Research Laboratory, London.

Conclusions. — (1) The eggs of *Haematopinus asini* may take 1 month, or more, to hatch. Animals undergoing treatment for the destruction of this louse must consequently be kept under observation for at least 34 days after the commencement of treatment. It has not been possible to determine the minimum time which should elapse between the laying of the egg and the fertile female, but, from analogy, it ought probably be a fortnight, for it has been found that in insects of this class the periods of maturation and incubation are approximately equal. This would mean that supposing all active stages are destroyed at each insecticide treatment and that the treatments are repeated at 10 days interval, at least 4 treatments are required, because, even if no eggs were laid during the treatment, it is very probable that, if that period is reduced, a few eggs existing at the commencement of the treatment may hatch out after 1 month and cause a new infection.

(2) The normal period of incubation appears to be from 16 to 20 days ; the minimum period, in natural conditions from, 15 to 16 days.

(3) A very limited amount of dry heat destroys the eggs. Even at blood heat, 24 hours in dry air prevented the eggs from hatching. It is evidently due to temperature that lice migrate during hot weather to the sheltered parts of the body. The eggs are usually laid close to the skin and, in partly clipped horses *the lice migrate* to the unclipped parts.

(4) Moist cold destroys the eggs, while dry cold has only the effect

of prolonging, by a few days, the period of incubation. It has not yet been possible to determine how long they can stand dry cold, but a week in a dry cold room at a temperature of about 50° F. destroyed about 50 % and prolonged the incubation period (normally 16 days at 100°F.) of the others to 18 days.

70 – **Determination of the Activity of Malleins.** — Fava, E. in *Il Nuovo Ercolani*, Year XXIV, No. 16, pp. 193-198; N° 17, pp. 209-218, 1 diag., 6 tables, Turin, Aug. 31 and Sept. 15, 1919.

The author insists on the expediency of extending State control to specific products, which might be of use in the diagnosis of infectious diseases. The toxic power of mallein can only be estimated by experimenting with this substance on animals suffering with glanders; the author proposed to determine if it was possible to obtain sure results by employing for the purpose guinea-pigs attacked by glanders. He used malleins prepared in 7 different Institutes: — Italian, French and Swiss he diluted them with physiological salt solution containing 0.85 % of sodium chloride in decreasing proportions from 1 : 3 to 1 : 200 ; a quantity of the dilutions thus prepared was mixed with an equal volume of fresh superimmunised serum in a first series of tests ; with one half of the volume of serum in a 2nd series ; with 2 volumes of serum in a 3rd series. The mixtures thus prepared, rendered homogenous by shaking, were heated to 37° C., and read after ½, 1, 2, and 4 hrs, then placed at a laboratory temperature, and read at the 20th hour. A series of tables gives the results of these experiments of precipito-reaction.

The malleins were tested in parallel on guinea-pigs given glanders by means of a bacillary emulsion, obtained from 24 hr. cultures in glycerined agar, from a stock taken from the ass.

Some guinea-pigs were experimented on with malleins, 36 to 48 hours after the appearance of specific symptoms, others at an advanced stage of experimental contamination. The different malleins were given by an intracerebral injection, in doses of 0.05, 0.10, and 0.15 cc. diluted in an equal volume of 0.85 % physiological solution, and by an intravenous injection in a dose of 0.50 cc, diluted in a triple volume of physiological solution; 2 tables give the results so obtained.

The author remarks that the intracerebral injection does not allow of the exact estimation of the toxicity of malleins in guinea-pigs suffering from glanders, because the peptone contains amino bases (especially tyramin), which may cause in intracerebral innoculations a symptom resembling an anaphylactic shock.

Conclusions. — (1) The control of malleins, on subjects suffering from glanders (guinea-pigs), requires much time, and consists of a complex, delicate, dangerous and costly method. Moreover, this method does not always give constant results, because of the intervention of the personal factor, which is not to be neglected, even if animals of the same age, of almost the same weight, infected by the same virus, and with the same quantity of it, are operated on.

(2) In the preparation of serum against glanders, BERTETTI and FINZI used precipitogenous substances from *Bacillus mallei*, which give rise to super-rich serums of specific precipitins.

Functional groups (haptophorous and precipitophorous group) of precipitable substances, (malleins), which, in the case specified, are the above-mentioned immunising precipitogenous substances, find their corresponding specific in the precipitins of super-immunised serum against glanders.

(3) The precipito-reaction, obtained with super-immunised serums against glanders, is absolutely useful and practical because of its easy use, its simplicity, and its certainty in the estimation of the toxicity and of the activity of the malleins put on the market.

(4) The greater the degree of dilution, at which it contains sufficient quantity of precipitable substance, able to react with the precipitins of super-immunised serum against glanders, the more active is the mallein.

71 – **The Control of Cattle Plague in Indo-China.** — SCHEIN, H. (Veterinary surgeon at the Pasteur Institute of Nhatrang, Annam), in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 3, pp. 65-73. Saïgon, March, 1919.

Cattle plague is the most feared epizootic disease in Indo-China, where it has been known from the remotest times.

The author studies the disease, passing rapidly over well-known general facts, laying stress on the local conditions, and on the latest scientific opinions, so as to determine clearly the present state of that important question so far as Indo-China is specially concerned.

SPECIES ATTACKED.— All domestic and wild ruminants. Sheep and goats themselves are liable to contract the disease, and to transmit it. The Pasteur Institute at Nhatrang has recently proved that the Indo-Chinese goat is at least as liable as the buffalo to the innoculated disease, thus constituting an excellent subject for experiment. M. M. CARRÉ and FRAIMBAULT, at that Institute, have shown that, contrary to what was thought, the pig can be infected and a transmit the disease.

Wild ruminants, or wild boars, beasts of the forest are therefore liable to preserve and spread the virus. But infection by them is uncertain and accidental, and if we are defenceless against it we must nevertheless fight against the disease.

China constituted for Indo-China a veritable reservoir of virus ; while cattle plague has disappeared from Annam, Tonkin is still, most certainly by Chinese infection, ravaged by it. This is a most useful indication : if cattle plague is not endemic in Indo-China, it would be possible to obtain its total suppression (1), by an energetic use of all the available measures.

SENSITITIY OF VARIOUS BREEDS. Annamite cattle are relatively very slightly sensisitive to virus. Letting the disease spread freely, the mortality varies from 30 to 50 % of those attacked. On the contrary, the improved breeds, resulting from crossing with European cattle, as well as

(1) See *R.* March, 1919, No. 333. (*Ed.*)

buffaloes, pay a much higher toll, which may be as high as 90 % of the animals attacked. Nothing is at present known regarding the relative susceptibility of the other breeds (of Cambodia, Yuman, Jhanh-hoa, etc.)

INDIVIDUAL SENSITIVITY. — In various countries (the Philippines, Erythrea), it has been noticed that animals living on the heights are less affected than those living in the lowlands. The buffalo, pre-eminently an animal of the lowlands, is extremely sensitive.

But possibly there may be resistance to infection through immunity. (1) Hereditary immunity (by Darwinian selection) (1) active immunity (by previous attacks; this is the most effective; (3) passive immunity by the antitoxins of the serum of the mother's milk, for the young who are sucking.

The anthor describes the symptoms, diagnosis, injuries, bacteriology, sanitary precautions, antiplague serum.

ANTIPLAGUE SERUM. — It was discovered, and brought to notice, simultaneously by KOLLE and TURNER, in South Africa, and by CARRÉ and FRAIMNAULT at the Pasteur Institute of Nhatrang. Since then improvements have been made in its preparation, tending mainly to reduce the net cost. The most important is due to M. NICOLLE, who at the Pasteur Institute at Constantinople, substituted for virulent blood the liquid from peritoneal washing of an animal suffering from the disease, as the source of virus intended for super-immunising the animals producing serums. There are two methods of serotherapy : — " sero-infection " which is a true vaccination (a mild form of the disease is given to the subject), and " passive immunisation ", by the use of serum alone. According to the author, sero-infection is the better process.

Great care should be taken, when a newly imported animal is being injected, not to inoculate it with germs of other diseases, or protozoa.

The author concludes that the most formidable of cattle infections in Indo-China may be considered as conquered, and that, if it is really desired, breeding could become a very great source of wealth of the colony, and a valuable source of preserved and frozen meat for France.

72 – **Haemorrhagic Septicaemia in Indo-China.** — SCHEIN, H., in *Bulletin Scientifique de Saïgon*, Year I, No. pp. 257-264. Saïgon, Sept., 1919.

The question of haemorrhagic septicaemia has led to lively controversies in Indo-China. Up to 1919 all the cattle diseases, in this colony, were included under the name of " cattle plague ", thus denying the existence of haemorrhagic septicaemia; then there was too much generalising in the opposite sense, by denying even the existence of cattle plague. The two epizootic diseases most certainly exist as the works of the author (Bacteriologist at the Pasteur Institute at Nhantrang, Inspector of Epizootics), made in collaboration with M. YERSIN, have affirmed.

The author, owing to the interest which the question presents, drew up a statement : — on haemorrhagic septicaemia (describing its 4 forms, super-acute, acute, sub-acute and chronic), on its treatment, (intravenous injections of iodine, carbolic acid, collodial silver or aniodol used internally, mild laxitives, alcohol, bitters (nux vomica), rich, nutritive and easily

digested food) — of bacteriology, — of the diagnosis of vaccination, and of serotherapy (it appears that fairly good results can be obtained by vaccination with the bodies of microbes, killed by glycerin, and injected with the latter according to Dr Bernard's method for the preparation of the anti-staphylococcic vaccine, on prophylaxis.

73 - **The Control of Parasitic Flies on Sheep in Australia by Spraying with Insecticide** (1). — McDonald A., H. E. in *Agricultural Gazette of New South Wales*, Vol. XXX, No. 6, pp. 403-405, 3 fig. Sydney, June, 1919.

Experiments carried out at Trangie Experiment Farm, New South Wales, Australia, with the object of confirming the efficacy of spraying insecticides on sheep (by forcing a strong jet of the liquid into the wool) as a measure of protection against the blow fly or blue-bottle fly (*Calliphora* spp.), show that, although this treatment does not give complete protection, it, however, reduces considerably the number of sheep attacked since, on the average, the proportion was 33 % in the flocks treated and 54 % in the untreated flocks.

The insecticides used in the experiments were an arsenical sheep-dip powder, a carbolic dip and a mixture in which the active agent was arsenite of soda. All were applied by means of a very strong jet with a diameter of about ½ inch, using a pressure of about 60 lb. During the treatment the wool was not clipped because it was required to hold the insecticide and to enable the maggots present in the wood to be poisoned. The application was repeated a second time 6. weeks later.

It appears that this treatment localises attacks, but further research is necessary.

74 - **Efficacy of Leguminous Plants of the Genus *Deguelia* (= *Derris*) in Fighting Parasitic Insects and Mites in Domestic Animals.** — See No. 143 of this *Review*.

75 - **Diseases of Pigs in Albania.** — See No. 99 of this *Review*.

76 - **The Acid-Base Balance in Animal Nutrition; Metabolism Studies on the Effect of Certain Organic and Mineral Acids on Swine** (2). — Lamb, A. R. and Evvard J. M. (Iowa Agricultural Experiment Station, Ames), in *The Journal of Biological Chemistry*, Vo. XXXVII, No. 2, pp. 329-342. Baltimore, Feb., 1919. FEEDS AND FEEDING

Metabolism studies undertaken by the authors on live pigs to obtain definite information regarding the transformation of lactic, acetic and sulphuric acids in the body of the animal to which they were fed.

Results. — With a ration containing an abundance of calcium the animal apparently oxidised the organic acids completely without increase of ammonia in the urine, and these acids apparently caused a slight increase in the retention of calcium.

With the same basal ration plus 300 cc. of normal sulphuric acid solu-

(1) See also *R.*, Nov. 1914, No. 1017 *R.*; April 1915, No. 401 and *R.*, Oct. 1915, No. 1051; *R.*, Dec. 1916, No. 1295; *R.*, Dec. 1918, No. 1874. (*Ed.*)

(2) See *R.* April, 1919, No. 485. (*Ed.*)

tion a day, 61 % of the acid ingested was neutralised by the ammonia excreted and 5 % was excreted as phosphates.

With another basal ration, very poor in calcium, extra ammonia excretion accounted for 76 % of the ingested acid and extra urinary acidity for 10 %.

With neither of the above noted rations did the mineral acid cause a significant loss of calcium, nor did it interfere with the storage of protein.

77 – **Vitamines in Green Fodder.**— Osborne' T. B. and Mendel, L. B. with the cooperation of Ferry, E. L. and Wakeman, A. J. in *The Journal of Biological Chemistry*, Vol. XXXVII, No. 1, pp. 187-200, 3 pl. Baltimore, Jan, 1919.

The authors have studied the presence in certain green plants, of fat-soluble and water-soluble vitamines by means of feeding tests on rats. In order to test for each of these vitamines, the product under study was fed in a ration rich in the other kind of vitamine. The following vegetable foods were tested :— leaves and stalks of spinach ; whole inside leaves of cabbage ; whole young plants of alfalfa, clover and timothy grass ; after drying in the air at 50-60°, then finely ground.

The results obtained indicate that 10 % of spinach furnished a little less than the required amount of water-soluble vitamine, while the rats obtained abundance (for normal development) of fat-soluble vitamine ; 145 % of cabbage leaf appears to be equivalent to about 10 % of spinach in respect of water-soluble vitamine. Preliminary experiments with the other plants indicate that the content in water-soluble vitamine of clover and timothy grass is similar to that of cabbage, while alfalfa is a little richer. The content of fat-soluble vitamine appears to be very high.

According to the few data at present available, green vegetables supply an important addition to human diet, because the staple foods (cereals, potatoes, sugar, meat, fats, etc.) furnish too limited a quantity of either of these vitamines to satisfy wholly the requirements of an adequate diet.

78 – **Supplementary Relationships between the Proteins of Certain Seeds.** — Mc Collum, E. V., Simmonds, N., and Parsons H. T., in *The Journal of Biological Chemistry*, v. XXXVII, No. 1, pp. 155-178, 7 diagr. Baltimore, Jan., 1919.

Study of the values of different mixtures of proteins furnished by 2 seeds, one of which (linseed or millet) furnished $\frac{1}{3}$ and the other (barley, wheat, maize pea, kaffir corn, soya bean, rolled oats, cottonseed flour, rye) furnished $\frac{1}{4}$ of the total protein of the food mixture. The total quantity of protein fed represented 9 % of the dry food mixtures. Records were made of the growth and variations from normal in ordinary functions of the adult animal (rats), such as reproduction and nursing the young. Individual differences of vitality were compensated by data being obtained from a group of 4 or 5 animals fed at the same time and with the same rations.

Results. — Generally, the proteins of the two seeds did not supplement each other to any appreciable extent.

The best growth curves were obtained with a mixture of linseed (furnish-

ing ⅓ of the protein) and rye (furnishing ⅓ of the protein), and with a mixture of pea (furnishing ¼ of the protein) and millet (furnishing ⅓ of the protein).

Reproduction was better, in all cases, with a mixture of proteins from the 2 seeds than with protein furnished by one seed only.

79 – **The Nutritive Value of Coconut Globulin and Coconut Cake.**— Johns, C. O., Finks, A. J., and Paul M. S. in *The Journal of Biological Chemistry*, Vol. XXXVII, No. 4, pp. 497-502, 4 diagr. Baltimore, Apr. 1919.

Coconut cake is chiefly used for feeding milch cows to obtain milk with a high fat content. The consumption of the cake has increased enormously during the last few years in the United-States. During the financial year ending June 30, 1918, 486 996 112 lb. of copra were imported into the United States ; this was four times as much as the quantity imported in 1916. Coconut oil is used to a great extent in the manufacture of oleomargarine ; the cake contains about 10 % of oil and from 17 to 18 % of protein, composed chiefly of globulin which contains about 17.5 % of nitrogen and the following percentages of amino-acids : — Cystine 1.44, arginine 15.92, Histidine 2.42, Lysine 5.80, that is to say all the amino-acids necessary for growth as well as tryptophane.

The chemical composition of the protein of the coconut showed that it was of high quality and feeding tests made by the authors (on rats) have fully confirmed this.

It has been proved that : — (1) The globulin of the coconut produces normal growth when used as the sole source of protein in an otherwise complete diet.

(2) Commercial coconut cake furnishes the necessary amount of protein for almost normal growth.

(3) This cake contains sufficient water-soluble vitamine and also some fat-soluble vitamine, but the rate of growth is increased by adding butter fat to the ration.

80 – **Importance of Salt in Food Rations of Cattle.** — Joffe, J. in *Journal of Dairy Science* Vol. II, No. 3, pp. 159-169, bibliography of 8 titles. Baltimore, May, 1919.

The author purposed to review the literature on this subject, to bring to light the opinions put forward recently on the matter and if possible to draw practical conclusions from them. These conclusions may be summarised as follows : — Want of salt in the rations causes pathological conditions and gives rise to a loss of live weight and of vitality and, consequently, a decrease in yield. The experimental data worked out by the author indicate that the necessary amount of salt, according to the rations, should vary between 36.6 gm. and 40. 7 gm. per day for each milch cow in the cowhouse. Some foods, such as soya beans and Kafir corn (a variety of sorghum) require a larger amount of salt. At the Agricultural Experiment Station of Kansas only salt obtained by evaporation is used, rock salt being too coarse and irritating.

BREEDING

81 – **Colour Inheritance in Mammals.** — Wright, S. in *The Journal of Heredity*, Vol. VIII, No. 5, pp. 224-235 ; No. 8, pp. 373-378 ; No. 9, pp. 426-430 ; No. 10, pp. 473-475 and 476-480 ; No. 11, pp. 521-527 ; No. 12, pp. 561-564 ; Washington 1917 ; Vol. IX, No. 1, pp. 33-38 ; No. 2, pp. 87-90 ; No. 3, pp. 139-144 ; No. 5, pp. 227-240. Washington, 1918.

I. — The author attempts to establish relationship between biochemical discoveries relating to melanism and the correlations between different colours described in works on genetics. He proposes a scheme by which the reciprocal relations between the different colours of the cost of mammals can be indicated and he recommends the following classification of colour factors :—

(1) Factors which influence distribution and intensity of colour, largely irrespective of the kind of colour : —

a) Factors which influence the distribution of colour in contrast with white ;

(*b*) Factors which influence the intensity of colour in all coloured parts of the skin, fur, and eyes.

(2) Factors which influence the distribution and the intensity of differentiation from yellow to black, effects naturally visible only in coloured parts : —

(*a*) Factors which influence the distribution of a dark colour (black, sepia, brown, etc.) in contrast with yellow ;

(*b*) Factors which influence the intensity of only the dark colours with effects visible whereever these colours appear (skin, fur, eyes).

II. — Mice. — The author states in detail the present state of knowledge relating to colour inheritance in these animals. He gives a list of 7 sets of Mendelian allelomorphs which have been identified and of 3 sets of colour variations which have not yet been analysed. These are classified according to their physiologically visible effects in conformity with the previously mentioned scheme.

III. — Rats. — Data regarding colour inheritance in rats consist chiefly in the interpretation of results of selection experiments on hooded rats (grey with black head and narrow mid-dorsal stripe) carried out by Castle, W. E., *American Breeders Magazine*, No. 3, pp. 270-282 ; 1912 ; *American Naturalist*, Vol. 48, pp. 65-73, 1914 ; Vol. 49, p. 37 and Vol. 713-726, 1915 ; Vol. 51, pp. 102-114, 1917 ; Castle W. E. and Wright S., *Sci. N. S.*, Vol. 42, pp. 191-195, 1915 ; Castle W. E. and Phillips, J. C., *Carnegie Institution Washington Publication* No. 195, 56 pp., 1914 ; Castle, W. E., *Ibidem Publication* No. 241, part iii, p. 161-187, 1916.

The author concludes that genetic variations occur sufficiently often to give a basis for selection which might be carried on indefinitely. " Under any interpretation Castle's, selection experiment demonstrates the efficacy of Darwinian selection. It is true that one large mutation occurred with effects perhaps as great by itself as the entire plus selection series, but where such a variation gives one new level, selection has produced a continuous series of stable levels. This would give selection of small variations a more important place in evolution and animal husbandry, where it is nice adjustments of one character to another or to the environment, that count ".

IV. — Rabbits. — The author enumerates the 10 unit differences known to exercise influence in colour inheritance in rabbits. These are classified in 7 independent sets of allelomorphs, of which 3 have been proved to be triple allelomorphs. These 3 sets of allelomorphs, as in the case of many other mammals, determine a linear series of physiological effects which are inexplicable as linkage of factors in the germ cells.

V. — Guinea pigs. — In the guinea-pig, as certainly in other animals, the spots on the coat must be determined by a collection of causes of very diverse kinds. There are hereditary factors of many kinds and factors which are of the nature of accidents happening during development. Certain factors influence the development of the spots and others determine their position. Of the latter, some assign the spot to the axis of symmetry and organs of the body others determine the position at random. Some factors influence only the tortoiseshell or the piebald coloration in one way or another, while others have a simultaneous influence on both. The result is such a diversity of pattern among tri-coloured animals, that a rough sketch will *identify* almost any animal in a group of a thousand.

VI. — Cattle. — The author, considering the inheritance of the colour roan, maintains that the data furnished by Wentworth (*American Breeders Magazine*, No. 4, pp. 202-208, 1913 — *Journal of Agricultural Research* Vol. 6, pp. 141-47, 1916) do not confirm the 2 factor hypothesis enunciated by that writer, but rather the idea of a single factor without dominance ; he explains the exceptions by means of subsidiary hypotheses. The results published by Lloyd-Jones and Evvard (*Research Bulletin* No. 30 *Agricultural Experiment Station Iowa State College of Agriculture*, 1916), showing that white is independent of red and of black are regarded as contrary to the theory of "polygamous factors" (multiple allelomorphs) enounced by Wilson (*Sci. Proceedings of the Royal Dublin Society*, p. 11, 1918) to explain the roan coat.

Contrary to Wilson (*Sci. Proceedings of the Royal Dublin Society*, pp.12-66, 1909), the author considers that the colour dun (dull brownish black ; the hairs showing a yellowish tip and the yellow colour tending to predominate especially along the mid-dorsal line) is due to a diluting factor combined with black. The same factor combined with red produces yellow or cream. Brindling (that is to say the presence of irregular black streaks, or of a deeper black if the ground colour is black also) has not been analysed in a satisfactory manner. Piebald is independent of colour, but, on account of the few data available, the interpretation of the factors of the different spots cannot be attempted.

VII. — Horses (1). — In these animals 7 pair of independent allelomorphs are recognised. Generally the works of the different writers supplement and confirm each other. The author is unable to explain certain facts exhibited by horse hybrids, especially the occurrence of chestnut mules since that colour has never been seen in the ass and is recessive in the horse.

VIII. — Pigs. — The author collects the fragmentary data published

(1) See *R.*, Dec., 1917, No. 1188. (*Ed.*)

on the subject of colour inheritance in these animals. White in Yorkshires is dominant over red and over black as has been shown by Smith (*American Breeders Magazine*, No. 4, pp. 113-123,1913), but it differs from the dominant white of other mammals inasmuch as that breed never transmits red when crossed with black, nor black when crossed with red. The author puts forward the idea that, in the case of Yorkshires, white is an extreme dilution of red accompanied by complete absence of extension of black.

The absence of the factor of dilution and the presence of a partial extension of black gives as result a black coloration with the white points of Berkshires and Poland Chinas. A change in minor factors causing an intensity of red and a restriction of black transforms this colour into self red in Duroc Jerseys and in Tamworths. The replacing of the factor " partial extension of black " by the factor " total extension " gives as result a self black coat as in the Essex breed, while the addition of the factors of the white band has for result the coat of the Hampshire breed.

IX. — Dogs. — For the colour of the coat, 5 pairs of unit characters have been more or less clearly distinguished.

X. — Cats. — The most curious fact regarding colour inheritance in these animals is that tortoiseshell fur (yellow mixed with black) is rarely found in males.

The theories put forward to explain it assert that an orange male crossed with a black female will only produce black males and tortoiseshell females. Tortoiseshell females crossed with orange males should produce black males and an equal number of tortoiseshell and orange feamles.

However, in both crosses only black females and tortoiseshell males were registered. The author notes that these discrepancies are much more numerous among the female than among the male descendents and, consequently, the variations cannot be left out of account as errors in the record. It appears that, for colour inheritance in the fur of cats, there are 7 pairs of well-defined allelomorphs.

XI. — Man. — The author sums up briefly the data available on the subject of colour inheritance for the hair, the colour of the eyes, premature grayness, albinism and locks of white hair.

HORSES

82 – **French Horses in America, especially in the United States.** — Grau, Alfred, in *Journal d'Agriculture pratique* Year LXXXIII, No. 40, pp. 808-812, 2 figs. Paris Nov. 6, 1919.

It seems most probable, that, among the French breeds of horses, the draught, and particularly heavy draught, breeds will come to the front, owing both to their less delicate constitution, and the greater success in their production, and of their more ready and advantageous sale.

French breeds of draught horses have long been universally appreciated; in America, and in the United States in particular, they are the most appreciated. This is a very interesting fact for French export.

Americans prefer quiet and powerful animals, as large and heavy as possible.

Whether from the drier climate, or for some other reason, these breeds,

once they have been exported to North America, have a tendancy to fine down, and to decrease in weight and size at the end of several generations ; for this resason, it is necessary to renew the blood frequently by good sires.

Among the draught breeds in France, some, such as the Nord and Ardennes draught horse, have suffered much from the war, and it will take time and much trouble to restore them, but these will not be lacking.

Compared with these breeds, the others such as the Boulonnais, Percheron, Nivernais breeds, the mule producing breed of Poitou, the Breton draught horse have not suffered.

In the United States, out of 100 horses, 82 are Percherons, 12 Belgian and only 5 or 6 English heavy draught Clydesdale or Shire stallions.

French breeds have the greatest future in America, and it is incumbent on France to continue her efforts, especially as regards selection.

CATTLE

83 - **French Cattle in Brazil.** — De la Vaissière, in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. V, No. 29, pp. 780-781. Paris, Oct. 1, 1919.

M. A. Crozier, (Directeur de l'Office National du Commerce Extérieur), transmits a report of the author, French vice-consul, at Porto-Alegre, on the possibilities of export of French cattle to Brazil.

Great efforts are being made, under the auspices of Dr. C. Dillon, H. B. M. Consul at Porto-Alegre, to group the breeders of stud animals in the United Kingdom, with the object of establishing a flow of export of the above mentioned animals towards the Rio-Grande-du-Sul, as was done for many years for the Argentine Republic.

From the standpoint of cattle which hold the first place in the breeding of that part of Brazil the breeds which are most interesting are the Flemmish (red coat) the Normandy, and also the Charolais. There is, therefore, a good market there for young bulls and heifers of the above-mentioned breeds, and the author draws the attention of French breeders of stud animals to this question.

84 - **Milk Substitutes in Feeding Calves.** — Caldwell, R. E., in *Journal of Dairy Science*, Vol. II, No. 4, pp. 312-329, 15 fig. Baltimore, July, 1919.

In the United States milk and its products supply about 19 % of the food consumed by man in normal times ; it is therefore essential to find adequate substitutes for feeding calves This question has been studied for 5 years at Purdue University Agricultural Experiment Station.

The experiments described in the work under review served to compare the utilisation of nitrogen in 3 rations, one containing liquid blood, the second vegetable protein and the third milk only.

A calf (No. 1) received milk, ground maize, oats and clover hay. The milk was replaced by a mixture of 1 part (by weight) of linseed meal + 1 part of " red dog " flour + 1 part of hominy + 4 parts of liquid blood. When the calf was 110 days old, it was given a ration which only differed from the former by containing dry instead of liquid blood and the 4 ingredients in the milk substitute were in equal parts.

A second calf (No. 2) received milk and a dry mixture of 5 parts of ground

maize + 5 parts of gluten feed + 5 parts of " red dog " flour + 2 parts of buckwheat flour and clover hay as roughage.

The milk was later replaced by a mixture of the same ingredients composing the dry mixture with the addition of an extract obtained by boiling clover hay in water until the liquid portion contained 1 per 1000 of nitrogen. When this calf was 110 days old he was placed on the same ration as calf No. 1 in the first part of the experiment. Two other calves (Nos. 3 and 4) received milk, ground maize, oats and alfalfa hay. They served as control to the two preceding calves. When calf No. 3 was 100 days old, it was given the ration which was fed to calf No. 2 during the first part of the experiment. When calf No. 4 was 90 days old, it received the ration which had been fed to calf No. 1 during the first part of the experiment. The 4 bull calves were of the Holstein breed.

All the calves were placed in digestion crates ; the quality and quantity of their excreta were recorded daily. The calves were weighed every 10 days and photographed every 30 days.

A series of tables indicate : — The consumption of nitrogen and the percentage of nitrogen which each feed supplied for each of the 4 calves ; the quantity of nitrogen fed to, excreted and retained by each calf ; the gain in live weight every 10 days (on the average, the daily gain was 1.15, 0.68, 1.08, and 1.81 lb. respectively for the four calves).

The amount of nitrogen fed in the food increased, for calf No. 1, from 39.192 gm. per day between the 20th and the 30th day of age to 114.595 gm. between the 130th and the 140th day, with a maximum of 115.100 gm. and there was, during the 120 days above noted, a total of 11138.710 gm. and, on the average, 92.822 gm per day. The respective figures for the other calves were: — *Calf* No, 2, from 38,354 gm. between the 1st and the 10th day of age, to 66,118 gm. between the 110th and the 120th day, with a maximum of 72.025. gm. total for the 120 days 6451.910 gm.; daily average 53.766. gm.

Calf No 3, from 27.942 gm. between the 20th. and the 30th. day of age to 67.944 gm. between the 130th day and the 40th day, with a maximum of 83.808 gm.; total for the 120 days 7289.240 ; daily average 60.745 gm. — *Calf* No. 4 from 11.458 gm. between the 20th and the 30th day of age, to 75.541 gm. between the 130th day and the 140th day ; with a maximum of 87.232 gm. total for the 120 days 5784.69 gm.; daily average 48.205 gm.

The percentages of nitrogen excreted in the faeces of the 4 calves on the average for the 120 days of the experiment, were 34.24, 28.73, 31.07, 25.57, respectively, those for nitrogen excreted in urine were 42.16, 31.52, 31.00 and 36.12, those for nitrogen retained were 23.76, 28.81, 37.84, and 39.15.

Calf No. 1, which received animal protein in the form of liquid blood, consumed the greatest amount of nitrogen, retained less and excreted more in the form of urine than any of the other calves in the experiment. But the effective amount (in grammes) of nitrogen retained was equal to the average for the two calves fed on milk.

The excess nitrogen eliminated in the urine shows that the nitrogen

supplied by the liquid blood has high degree of solubility or absorption and serves as a guide, at least in some measure, in judging the desirability of a ration for calves. When calf No. 1 received dry blood instead of liquid blood, the amount of nitrogen consumed remained fairly constant, the retained nitrogen was equal to that previously retained and the excreted nitrogen changed from the urine to the faeces.

Calf No. 2, which received the vegetable protein ration, consumed a small quantity of nitrogen, retained the smallest quantity in grammes, and excreted the largest quantity in the faeces. The presence of milk or liquid blood increased the nitrogen in the urine to a point which agrees very closely with that given by the calves which received these foods.

Calves Nos. 3 and 4 retained the largest amount of nitrogen and maintained a more equal division of nitrogen elimination in the faeces and in the urine than the calves which received the substitute ration. Their behaviour when changed to other kinds of rations agreed with that of calves which received similar rations during the earlier periods of the experiment.

85 – **Can " Home Grown " Rations Supply the Proteins Necessary for High Milk Production?** — HART, E. B. and HUMPHREY, G. C., in *The Journal of Biological Chemistry*, Vol. XXXVIII, No. 3, pp. 515-527. Baltimore, July, 1919.

A ration composed of cereal grains, silage and clover or alfalfa hay is considered by some as sufficiently adequate in protein content for maintaining a high milk production. But in view of the new theory according to which the value (for growth or milk production) of a protein mixture depends upon its qualitative constitution and its quantitative composition and not merely on the quantity of proteins fed, it was necessary to determine directly by metabolism experiments whether the above-mentioned ration, entirely produced on the farm, could furnish protein for a high milk production without draining the protein reserves in the tissues of the animal. The ration used in the experiment was composed of maize stalk silage and clover hay to which ground oats were added in the 1st. period of 4 weeks, ground barley in the 2nd. period, ground maize in the 3rd. a mixture of approximately equal parts of the three grains in the 4th. period, all periods of 4 weeks. The amount of energy provided by the 4 rations was maintained constant by the addition of maize starch. The proportion of grains and starch fed to 3 cows (Nos. 1, 2 and 4) was in conformity to the rule 1 lb, of grain for 3 lb. of milk ; that of grains fed to 2 cows (Nos. 3 and 5) was larger than the normal.

The cows belonged to the Guernsey, Jersey and Holstein breeds. Cows Nos. 1 and 3 were good milk producers for they gave 34 to 37 pounds of milk daily when the experiment commenced. Although these cows were fed *ad libitum* they had a negative nitrogen metabolism from the beginning of the experiment for 5 or 6 weeks, during which time their milk production decreased gradually to a point where the ration consumed maintained a state of nitrogen equilibrium, which was reached before the end of the second period of 4 weeks.

Cow No. 1, during the 8 weeks when she was put on a ration of oats fol-

lowed by barley, decreased the amount of nitrogen secreted in the milk by over 100 gm. per week ; this quantity decreased by over 150 gm. per week in the case of cow No. 3. On December 3, cow No. 1 produced 33.8 lb. of milk and on February 3, only 23.7 lbs. cow No. 3 gave 36.9 lb. on December 3 and 25.9 lb. on February 3. Cow No. 2 consumed a large amount of food but she gave less milk than cows Nos. 1 and 3, which enabled her to maintain herself in nitrogen equilibrium on the grain ration + silage + clover hay. The amount of nitrogen secreted in the milk produced by her during a week scarcely decreased by 60 to 70 gm. ; the quantity of milk was also sensibly maintained ; it varied only from 23.7 lb. on December 3, to 20.1 lb. on March 17. These results show clearly that ordinary " home grown " foods suffice only for a moderate milk production. The data set forth in the Table below confirm the conclusion that the essential change incident to an intake of protein insufficient both in quantity and quality for nitrogen equilibrium in a milking cow is a rapid decrease in the secretion of milk and not a change in the percentage composition of the milk.

Decrease in quantity of milk produced by cows in negative nitrogen balance, but maintaining the percentage composition of the milk.

	Cow No. 1		Cow No. 2		Cow No. 3		Cow No. 4		Cow No. 5	
	Dec. 16	Jan. 13	Dec. 16	Mar. 10	Dec. 16	Jan. 13	Feb. 10	Mar. 10	Feb. 10	Mar. 10
Milk daily . . . . . lb.	32.7	26.8	24.3	21.2	32.6	26.0	32.9	19.6	31.3	23.0
Total solids . . . . . %	13.57	13.52	14.27	14.17	13.07	12.73	10.96	11.90	12.07	12.58
Fats. . . . . %	4.60	4.45	4.70	5.10	4.10	3.50	2.80	3.50	3.10	3.60
Nitrogen. . . . . %	0.49	0.47	0.53	0.53	0.46	0.47	0.41	0.48	0.50	0.49

The mixture of oats, barley and maize was not better than rations containing a single grain. During the period of observation the live weigh of the animals gave no indication regarding their nitrogen equilibrium. Cows Nos. 1 and 3 lost heavily in weight under conditions of negative nitrogen balance : they changed respectively from 1024 to 935 lb. and from 885 to 762 lb. between December 2, and January. 20.

Cow No. 2 which was in nitrogen equilibrium during the 16 weeks of the experiment did not lose weight but did not increase appreciably for she changed from 1 088 lb. on December 2 to 1 199 lb. on March. 27 Cows No. 4 and 5, although in negative nitrogen balance during 4 or 5 weeks increased in weight respectively from 1356 to 1395 lb. and from 1135 to 1200 lb. between January 20 and March 17.

The animals in negative nitrogen balance decreased their production of milk by 8 to 10 lb. in 5 or 6 weeks : this amount would have a market value of about 50 cents.

The cost of the addition of 2 lb. of protein concentrates to the daily ration would therefore have been more than covered.

Conclusion. — A cow with a low milk production and a good appetite can be kept in nitrogen equilibrium with a " home grown " ration, but a good milk producing cow requires a supplement of protein concentrates to avoid loss of nitrogen and consequent decrease in the milk production.

86 - **Alfalfa as Sole Food of Dairy Cattle in the United States.** — Woll, F. W., in *Journal of Dairy Science*, Vol. I, No. 6, pp. 447-461. Baltimore, March, 1918.

The two most important changes in American agriculture during the past 25 years are the introduction of the silo in cattle farming and the introduction or the extension of alfalfa cultivation. The silo has spread from the east westwards and alfalfa from the west eastwards. At the present time alfalfa occupies over 30 % of the irrigated area of the United States and 7 % of the entire area under hay and fodder crops. The proper utilisation of a crop of this importance becomes therefore a most important economic problem both for the individual farmer and for the community. Furthermore, the fact that a very large number of farmers in the western States practise the method of feeding cattle exclusively with alfalfa has raised the question whether this practice is really the most economical. The author's research, carried out during more than 3 years at the California Agricultural Experiment Station, aimed precisely at clearing up this point and it was purposed to relate and discuss tbe principal results that have been so far obtained. The experimental data at present include 9 lactation periods for heifers fed, since the experiments began, exclusively on alfalfa, and 9 lactation periods for heifers of similar age, breed, etc., fed on rations of alfalfa hay, silage, and mixtures of various concentrates (mainly rolled barley, dried beet pulp, coconut meal, and wheat bran).

The influence of the two methods of feeding has been studied from the following standpoints : — Increase in live weight and body measurements during the tests ; the influence on the calves produced the heifers; the influence on the production of milk and butter during each lactation period ; the relation between the food consumed and the dairy production.

Influence on live weight and measurements. — The average gains in live weight were greater with mixed rations than with alfalfa alone, in both series of tests ; with the farmer the average gain was 1.11 lb. before calving as compared with 1.05 lb. for alfalfa alone ; during the entire period, the average increase was 0.60 lb. against 0.50 lb. per day, respectively, an average difference of 20% in favour of the mixed ration.

These results clearly indicate the nutritive superiority of the mixed ration compared with that of alfalfa alone, at least so far as gain in live weight is concerned. The increases in measurement were expressed in percentages and the figures recorded for both series in the period before calving and during the 1st and 2nd lactation periods were higher for the animals fed on mixed rations than for those which only got alfalfa. However, these differences disappear when longer periods or summary data for both lots are considered, except, however, the two measurements relating to length and girth. While these results are not conclusive, they

indicate a tendency towards a greater body development with mixed rations than with alfalfa only.

INFLUENCE ON THE CALVES DROPPED BY THE HEIFERS. — Since the beginning of the experiments there were 2 lots of 13 calves each comprising 6 Jerseys and 7 pure-bred or grade Holsteins. The calves dropped by the heifers fed on alfalfa weighed, on the average, 59.8 lb. at birth and those dropped by heifers on mixed rations averaged 64.4 lb, an average increase of 8 % for the latter. The experiments are at present insufficient to predict whether this difference will be maintained later with the growth of the calves, but a higher live weight at birth is itself a factor favourable to the future growth of a young animal.

INFLUENCE ON DAIRY PRODUCTION. — The animals under experiment have furnished up to date complete records of production and food con-

Food consumption and production, 1914-917.

sumption for 12 first lactation periods and 6 second lactation periods. The following Table shows the average production during the experimental period and the amount of food consumed. It will be noted that the mixed rations have proved decidedly superior to alfalfa alone so far as the production of milk and butter is concerned.

The average content of dry matter in the alfalfa rations was 24.9 lb. and in the mixed rations 28.6 lb; the nutritive ratios were 1 : 3.7 and 1 : 5.3 respectively.

For every 100 lb. of dry matter supplied in the ration of alfalfa alone, 70.7 lb. of milk and 2.82 lb. of butter were produced, against 79.4 lb. and 3.50 lb. respectively per 100 lb. of dry matter supplied in the mixed rations, an improvement in the latter over the former of 12 per cent. in the milk production and of 23 in the production of butter.

The explanation of these facts should be looked for in the number of calories furnished by the 2 rations. On the basis of the values given by ARMSBY, the alfalfa ration furnished 2.05 lb. of digestible protein and 9.9 calories, against 2.08 lb. of digestible protein and 15.4 calories for he mixed rations.

If the problem is considered from an economic standpoint, the practical results of feeding dairy cows may vary according to locality and the prices of foods. Taking the following prices of foods:—

Alfalfa hay, $2 per ton; green maize and green silage, $3; maize silage, $4; concentrates, $30; the cost for the 1st and 2nd lactation periods would be $56.34 and $61.49, respectively, using alfalfa alone, and $74.51 and $87.71 respectively for mixed rations an increase of $28.17 for the 1st lactation period and of $26.22 for the 1st. In these latter years farmers could not get a higher price than $8.00 per ton for alfalfa hay in stack, when concentrates cost $20 to $30 per ton. Evidently, under these conditions there is no gain in changing from the alfalfa ration to the mixed ration.

The problem can only be solved case by case, especially as there are plenty of examples of excellent results obtained by feeding with alfalfa alone. One herd of 23 stall-fed cows under test by one of the Cow-Testing Associations gave a general average of 410 lb. of butter fat on no other food but alfalfa throughout the year. However, it remains an established fact that mixed rations have an absolute superiority in the matter of production and growth, even if the superiority is only relative from an economic standpoint.

87 – **Relationship between the Quality of Proteins in Foods and Milk Production of Cows** (1) .— HART E. B. and HUMPHREY G. C., in *The Journal of Biological Chemistry*, Vol. XXXV, No. 2, pp. 367-383. Baltimore, Aug., 1918.

Two Guernsey cows and one Jersey were used in the experiments described in this paper. The daily production of milk of the 3 cows indicated by Nos 1, 2 and 3 was 22.00, 28.00, 24.20 pounds respectively. The ration was made up of 14 % of alfalfa hay, 56 % of maize stalk silage,

(1) See *R.*, Aug., 1915 No. 834. — *R.*, Aug., 1918, No. 888. (*Ed.*)

12 % of maize meal, and 18% of a mixture of starch and supplementary food. The nutritive ratio of the ration was 1 : 8.4. Total protein represented 10 % of the dry matter; 50 lb. of the ration furnished 2.32 lb. of digestible protein, of which about 37 % came from the supplementary foods; the production energy varied from 20.59 to 20.76 big calories. The nitrogen balance during the whole period of the test which lasted 16 weeks, was always negative no matter what the supplement was. During the test the cows maintained their live weight, but there was a slight decrease in milk production. The percentage composition of the milk remained almost constant.

The efficiency of the various rations is shown in the following Table:—

Absorbed nitrogen used for milk production by cows fed on alfalfa hay with various concentrates.

Concentrate	Cow No. 1	Cow No. 2	Cow No. 3
Gluten feed (gluten and maize bran ground together) .	40 %	43 %	43 %
Linseed meal	40	47	39
Brewers' grain	51	53	50
Cottonseed meal.	35	42	28

Earlier studies by the authors (1) showed that gluten feed is distinctly inferior, for milk production, to linseed meal and to distillers grain as supplements for proteins to the ration "corn stover" (2) + maize meal; that, on the contrary, as supplement to the ration clover hay + maize meal, gluten feed is practically equivalent either to linseed meal or distillers grain; the experiments now dealt with show that as supplement to the ration alfalfa hay + maize meal, gluten feed is equal to linseed meal, superior to cottonseed meal and inferior to distillers, grain. Cottonseed meal with the ration alfalfa hay + maize meal was the least efficient of the supplements.

Distillers grain was the most efficient of the supplements, perhaps because it contains the embryo proteins. An equally efficient protein mixture might be obtained by adding 10 to 15 % of maize germ meal to gluten feed.

These results once again show the limited value of any classification of natural foods in respect of the efficiency of their proteins based on the determination of that nutritive value in a single food or in a single mixture of foods.

88 – **Water Requirements for Milk Production.** — McCandlish, A. C. and Gaessler, W. G., in *Journal of Dairy Science*, Vol. II, No. 1, pp. 4-8, Baltimore, Jan., 1919.

Experiments carried out at the Iowa Agricultural Experiment Station, United States, with the object of determining the amount of water

(1) "Corn stover" = maize plants without the ears. (*Ed.*)

(exclusive of what is naturally contained in the food) required for milk production during the hot dry summer months by cows fed with fodder harvested on the farm. The cows were watered twice a day; the quantity of water consumed was determined by weighing the animals before and after watering. The moisture in the foods was determined, the amounts fed were weighed. The general results are set forth in the Table below. Results similar to those of the writers, obtained at the South Dakota Agricultural Experiment Station by C. LARSEN, E. H. HUNGERFORD and D. E. BAILEY (1) show that for 100 lb. of milk produced. 432 lb. of drinking water is required and a total of 570 lb. of water (in drink and food) is needed.

Production of milk and consumption of water by 5 milch cows.

Breed	Duration of the trial	Average live weight	Milk produced	Fat produced	Water drunk per 100 lb. of milk produced	Water drunk + water in food per 100 lb. of milk produced	Water drunk + water in food per 100 lb. of dry matter consumed
	days	pounds	pounds	pouuds	pounds	pounds	pounds
Jersey	50	834	972	44	320	512	506
Ayrshire	25	918	705	26	361	431	661
Ayrshire	15	1039	462	1	286	453	681
Guersey	50	1024	991	42	338	536	521
Holstein . . .	50	1224	875	34	424	678	518
Promedio. .	—	**1001.8**	—	—	**345.8**	**522**	**571.4**

CONCLUSION. — Water consumption is most important for milch cows. When a cow is fed on fodder and grain. about 350 lb. of water in the food are consumed per 100 lb. of milk produced and in addition about 200 lb. of drinking water will be needed; about 550 lb. of water will therefore be required per 100 lb. of milk produced during the summer months.

89 – **Dairy Cattle Feeding Experiments in Texas U. S. A.** — EWING, P. V., RIDGWAY, J. W. and DOUBT, W. A. in, *Texas Agricultural Experiment Station Bulletin*, No. 238, pp. 5-14. College Station, 1918.

I. — COTTONSEED MEAL V. GFOUNDNUT FEED FOR MILK PRODUCTION. — Two lots of 6 cows each were fed alternately by the reversal method during four three-week periods on two grain rations, maize chop and groundnut feed (in the proportion 1 : 1) and maize chop and cottonseed meal (3 : 2). The cows when on the peanut ration produced 178.7 lb. more milk and 8.85 lb. more butter fat than they did on the cottonseed meal ration, but owing to the fact that about 50 % more protein supplement was consumed, the increased production was not profitable, since groundnut feed and cottonseed meal were purchased at almost exactly the same price.

(1) See R., June 1918, No. 666. (*Ed.*)

A third lot of 6 cows fed during the entire 12 weeks on maize chop, groundnut feed and cottonseed meal (6 : 3 : 2) produced 583 lb. of milk and 1.08 lb. of butterfat more than the other cows when on the cottonseed meal ration. The third ration was considered the most economical of those tested. It is held that, under Texas conditions, where proteins are generally cheaper than carbohydrates, the proper basis for comparing feeds is the percentage of total digestible nutrients and not the protein content.

II. — Comparison of methods of preparation of velvet beans for dairy cows. — The grain mixture used in this experiment consisted of corn bran, cottonseed meal and velvet beans (2 : 1 : 3) and the roughage of pasture. Each of four different ways of preparing the beans (velvet beans = *Macuna pruriens* var. *utilis*) was tested in rotation with 4 lots of 3 cows, each lot receiving beans prepared by a particular method for 20 days. The amount of grain fed in each period was the same. The milk produced by the cows, when the beans were fed whole, totalled 6337 lbs., when the beans were cracked, 6345 lb., when cracked and soaked in water, 6398 lb. and when ground, 6690 lb. The feeding of cracked beans soaked, and of ground beans was accompanied by an increase of 7 or 8 lb. of butter fat. The increase in milk resulting from grinding was about 57 gallons for a ton of beans which at 40 cents a gallon is worth $ 22.80. Since mills will often grind the beans for $ 2.50 a ton, and the grinding can be done on many farms for $5, the operation is deemed distinctly profitable. No differences in palatability apparently resulted from the various methods of preparation.

90 - **Winter Rations for Dairy Heifers in Missouri U. S. A.** — Eckles, C. H., in *University of Missouri College of Agriculture, Agricultural Experiment Station Bulletin* 158, pp. 3-54, 16 fig. Columbia, Missouri, 1918.

This bulletin compares 15 rations with reference to their value and economy in promoting growth of dairy heifers during the winter months, and is based upon 76 individual feeds and growth records of heifers. Seventeen of the animals were included in the light-fed group of heifers forming a part of a previous investigation (1). The others were used in a series of feeding experiments conducted annually each winter from 1913-14 to 1917-18. Of the total number of heifers 31 were Jersey, 34 Holsteins and 9 Ayrshires. One of the Jerseys and one of the Holsteins were used two seasons.

For each of the animals the following data are published : — Age at the beginning of winter feeding, average daily consumption of each feeding stuff offered, digestible crude protein and net available energy of the daily rations (based respectively upon the average figures published by Henry and Morrison and by Armbsy), initial weight and height at withers, normal weight and height for animals of the same breed and age, daily gain in weight, total gain in height, and the gains in weight and height to be expected of similar heifers under normal conditions.

The Jerseys varied in age at the start from 6 to 20 months, the Holsteins from 7 to 21 months and the Ayrshires from 9 to 15 months. The feeding

(1) Summarised in *R.*, Oct. 1916, No. 1094. (*Ed.*)

periods were mostly 5 months. The data on normal growth are taken from those accumulated at the Missouri Station, of which a summary was given in article No. 1188 of the *International Review of the Science and Practice of Agriculture*, Oct.-Dec. 1919.

The combinations of feeding stuffs compared include: 1) Alfalfa hay alone; 2) alfalfa and silage; 3) alfalfa and maize; 4) clover hay and maize; 5) silage, alfalfa and maize; 6) silage, timothy hay and maize; 7) silage maize and cottonseed meal; 8) silage, timothy, maize, and cottonseed meal. A variety of different proportions of grain and roughage wes tested. It was found that animals fed a ration which resulted in heavy gain during the winter made only small gains the following summer on pasture. When the winter ration was so meagre that the animals were low in vitality in the spring fairly large gains were produced on summer pasture, but in most cases they were not large enough to compensate for the small winter gain. Neither extreme in winter feeding is considered economical. The best results, it is held, follow a winter ration that keeps the animal in moderate flesh and produces growth as nearly normal as possible. It was found that normal growth could be obtained from rations furnishing considerably less protein than that prescribed by the WOLFF-LEHMANN standard.

Of the 17 heifers wintered on alfalfa alone, only 2, both rather mature, made a gain in weight equal to normal. Although alfalfa is probably the most palatable roughage used for cattle in the United States and the quality fed was of the highest, still the animals did not consume enough to supply sufficient energy to allow for a greater growth.

The 15 heifers fed both silage and alfalfa made better gains than those fed alfalfa alone. The best gains occurred when both roughages were fed at will. On this ration animals more than 9 months old made practically normal gains. They consumed the silage and alfalfa in the proportion of 2:1. Younger calves needed grain in addition in order to grow normally.

The most satisfactory ration of all those tried was silage *ad lib.*, and legume hay limited to about 6 lb. daily and 2 lb. of maize daily. On this ration heifers of all ages throve and made gains somewhat above the normal.

Fair results may be obtained from silage alone for roughage, if legume hay is not available. In this case about 2 lb. of concentrates should be supplied daily, of which one half should be a high protein feed such as linseed or cottonseed meal, the remainder maize, or other grains if the cost is less a pound than for maize. The animals made better gains and seemed to be more contented if about 2 lb. of timothy hay per day was added to a ration of silage and grain.

Alfalfa or clover hay fed at will with 2 or 3 lb. of maize daily made a satisfactory ration for heifers of any age from 6 months to within a few weeks of freshening.

It is considered best to continue feeding grain to all heifers for a few months after the cessation of milk feeding. At a later age they can be fed exclusively on roughage if necessary without greatly retarding their

growth. It appears that Holsteins are able to make more nearly normal gains on a ration composed mostly of roughage than are Jerseys.

91 – **Winter Cattle-feeding Trials in Indiana, United States.** — SKINNER, J. H. and STARR, C. G. in *Purdue University Agricultural Experiment Station, Bulletin* No. 220, 26 pp., 1 fig. Lafayette, 1918.

With the object of following up previous work (1), relating to the study of the distribution of small rations of maize for fattening steers, and of making a comparison of the food values of silage composed of maize + soya beans and maize silage, a food test was made on 69 two-year old steers divided into 7 lots, lasting 120 days from December 13, 1917.

Lot IV received a medium ration of maize (12 lb. per head daily), except at the commencement of the trials. Lot III received half that amount and Lot I only got maize during the last 40 days of the trial. The steers were also given cottonseed meal to the extent of 2.5 lb. daily per 1000 lbs live weight, good maize silage and clover hay.

The three other lots were placed on a medium ration of maize ; two of them received in addition silage composed of maize + soya beans, and the third maize silage. This last lot and one of the lots which got silage composed of maize + soya beans received maize only as concentrate. The maize was of the same quality in the maize silage as in the silage composed of 2 parts maize + 1 part soya beans cut at the same time as the maize and when the pods were still green but with the beans well formed, and the leaves were beginning to turn yellow. The results are shown in the following Table :—

Results of the experiment.

Lots	Average daily ration of maize	Initial weight per head	Average daily gain in live weight per head	Pounds of food consumed per pound gain in live weight					Selling price per cwt.	Profit per head (not including profit on pigs)
				Maize	Cotton-seed meal	Maize silage	Mixed silage	Clover hay		
	lb.	lb.	lb.						$	$
I	* 4.15	1050	1.77	2.34	1.58	26.8	—	2.26	14.85	34.62
II	—	1050	1.66	—	1.69	32.6	—	2.51	14.55	35.55

VII	11.65	1044	1.79	6.50	—	20.7	—	2.38	14.65	27.44

* Lot I was given no maize during the first 80 days

Maize was valued at $1.12 per bushel ; cottonseed meal at $53.50 per ton ; clover hay at $25.00 per ton and the two kinds of silage at $7.50

(1) See *R.* June 1918, No. 668 and *R.* Aug. 1918, No. 887.

per ton. At these prices Lot II gave the cheapest gain per unit of live weight and Lot IV was second, but considering the smaller gain in live weight and the less finished condition of the steers, Lot II was not so profitable as Lot IV. There was no noticeable difference in the two silages used. The comparison of Lots IV and V with Lots VI and VII respectively seems to prove that the omission of a concentrate containing protein diminishes the economy in live-weight gain, the degree of finish attained by the steers, and the gain per head.

Each lot of steers was accompanied by pigs. The authors give the quantity of grain which the pigs ate and the pork produced, but as different quantities of grain were given to the pigs in the different lots and, insome cases, they were given tankage in addition, it is not possible to make any exact comparison between the lots of steers regarding the profit derived by feeding pigs with them.

92 – **Uruguay Sheep.** — Wilson, R. B. (Jefe de la Oficina de Estadística agrícola), in *Rivista del Ministerio de Industrias, República Oriental del Uruguay*, Year VII, No. 47, pp. 343-380, 11 figs. Montevideo, 1919. SHEEP

It is not known when and where sheep were first introduced into Uruguay; according to certain writers, it was at the beginingof the XII th. century. The sheep introduced belonged to two distinct breeds, which even after centuries of neglect and degeneration, have preserved their typical characters: the first, which became known as the " pampa " breed was derived from the " churra " type from Spain, which in turn partly owed its origin to a cross with breeds of English wool producers ; the second was called " criolla ". The " pampa " sheep was valued for its production of wool and " criolla " used only for meat.

In 1842, 991 040 kg of wool was exported from Uruguay, and in 1862, 286 3061 kg., in 1870, 12545 400 kg. Since then progress has been very rapid and constant, as the figures of the following table show :

Export of sheep and their produce from Uraguay from 1876 *to* 1900.

Quinquennial periods	Live sheep	Skins with fleece	Wool
1876–1880	79 782	16 770 063 kg.	80 861 820 kg.
1881–1885	435 282	23 269 718	125 388 799
1886–1890	289 010	36 286 934	163 375 865
1891–1895	438 699	28 807 657	172 593 083
1896–1900	866 291	33 534 732	201 609 880

From the end of the XVIIIth century rams of different breeds were introduced from Spain, France, England, Germany, and Austria, to im-

prove the sheep of the country, but the majority, as the improving breed, was of the Rambouillet breed.

On the occasion of the 1st, "Congresso Ganadero Agricola" (Congress of Stock breeding and Agriculture) organised by the "Asociación Rural delUruguay" at Montevideo, in 1895, the following resolutions were passed:—

(1) To improve and increase the yield of wool and meat, the early maturing pure Rambouillet breed should be adopted.

(2) In surroundings suitable to English meat breeds, these breeds should be used to increase the yield of meat.

The census of 1900 showed for Uruguay a total of 18 068 717 head of sheep and an annual production of 32 749 381 kg. of wool, that is to say, on an average, 18.12 per head. In 1908, there were 26 286 296 sheep and the census made in April, 1916, (that is to say before the lambing season) showed only 11 472 852. This heavy decrease (56 %) of the total number of sheep had been foreseen since the export of wool from 1912 (80 940 342 kg.) to 1916 (30 602 061 kg.) had decreased by 62 %. After that the total increased and for 1919 the author estimates it at abont 15 million head.

In 1902 the "La Frigorifica Uruguaya" Co., Ltd., was founded, which, in 1905, began exporting frozen mutton to Europe. Its production increased from 100 432 animals killed in the season 1904-1905, to 314 041 animals in 1911-1912, and 225 724 in 1912-1913. There was then a sudden and very heavy decrease during the whole period of the war.

The "Frigorifico Montevideo" (Swift Company) began work in 1912-1913 and in each of the years 1913 to 1918 killed 160 301, 108 791, 105 600, 128 940, 46 659, and 39 199 animals respectively, of an average live weight varying during the several years of that period, between 48 kg. and 57.6 kg., figures corresponding to an average weight of from 23 kg. to 29.3 kg. per animal, cut up and prepared for sale.

The frozen mutton industry, in consequence, has had for result the breeding of a greater proportion of meat breeds (Lincoln and such-like) and a smaller proportion of Merinos, as will be seem from the following figures: —

Breeds	Numbers	
	in 1908	in 1916
Merinos	6070701	4363013
Lincoln and such-like (White face)	1039821	6723040
Shropshire and such-like (Black-face)	226559	327483
Other breeds	176917	—
Breeds not specified	17402833	—
Criolla	1370025	59316
Totals	26286896	11472852

93 - **Tripoli Sheep.** — See No. 128 of this *Review*.

94 - **Sheep Feeding in the United States** (1).— SKINNER, J. H., and STARK, C. G., in *Purdue University Agricultural Experiment Station Bulletin* No. 221, 20 pp. La Fayette, Ind., 1918.

FATTENING LAMBS IN THE WESTERN STATES; TRIALS CARRIED ON IN 1917-1918. — This Bulletin includes 4 papers aiming at the determination: (1) of the influence of shearing practised some little time before sale of the lambs for slaughter; (2) of the possibility or otherwise of restricting the grain ration to the latter part of the fattening period; (3) of the use of hominy feed " (brewers grain + maize bran) as a substitute for maize. (4) of the value of linseed meal as a protein supplement; and aiming at obtaining also other data regarding soya beans as a protein supplement, the reduction of dry roughage and the increase of silage.

Commencing from October 28, 1917, 7 lots of 25 lambs each and 1 lot of 24 lambs were fed in the trials. The control lot was given maize and cottonseed meal (7 : 1) and, in addition, twice a day, maize silage + clover hay, and was sold with fleece.

The appendedTable indicates the modifications of this diet introduced for the other lots and the more important results obtained. Grain and supplements were mixed in the same proportion for all lots except the lot which was given no grain at the commencement of the feed trials and which was always given cottonseed meal (0,226 lb. per head per day) with silage. During the early days of the trials, all the lambs, except the last abovementioned lot, got a certain amount of oats, altogether about 11 lb. per head, to accustom them to a grain ration.

Under the market conditions at the time of the trials there was no profit. The sale price assigned to the control lot was $17.00 per cwt. The low average gain in live weight realised by the shorn lambs is directly due to the decreased consumption of silage consequent on shearing; the shorn lambs also lost in selling price. Although maize cost $1.12 per bushel and " hominy feed " cost $60.00 per ton, the lambs fed on the latter gave a higher profit because of the smaller consumption of the concentrate per unit of gain in live weight and because of an increase of 10 cents per 100 lb. in the selling price. Feeding with maize limited to part of the period of the trial gave a lower cost of feeding to the extent of about 12 cents per head compared with the control lot, but the lower gain in live weight and the decrease of 15 cents per cwt in the selling price caused a decrease in the profit.

Linseed meal and crushed soya beans were valued at $60.00 per ton and cottonseed meal was bought at $53.00 per ton. The food value of soya beans was equal to that of cottonseed meal; the sale price of the 2 lots which got the former or the latter in an otherwise similar diet, was identical. The difference in the profit is due to the difference in the cost of the food. The increased profit given by the lot which got linseed meal was

(1) For previous work, of which the trials published in *Bulletin* 221 are the continuation, see *R.*, June 1918, No. 669 and *B* May 1919, No. 623. (*Ed.*)

partly caused by smaller consumption of concentrates per unit of gain in live weight. Clover hay was valued at $25.00 and silage at $7.50 per ton, but neither feeding with hay every fifth day only (which reduced consumption by one half), nor completely ceasing to give hay after the 3rd week, that is to say when the lambs received full feed, was profitable because of the smaller gain in live weight.

Results of 90 days trial feeding of lambs.

	Average initial weight	Daily gain per head	Pounds of food consumed per pound gain in live weight				Profit (+) or loss (—) per head
			Grain	Concentrate	Silage	Hay

95 – **Feeding of Lambs: Trials in Kansas, U. S. A.** — *Kansas Agricultural Experiment Station Report, for the Year* 1918, pp. 43-43. Manhattan, 1919.

Comparisons were made between the following nutriments as feeds for lambs in the western United States:— shelled maize and whole kafir corn ; alfalfa hay and sweet clover hay ; silage and no silage. The trials lasted 60 days, during January and February, 1918. They began with 5 lots of 60 lambs each, but one lot was eliminated later on as it was not proving satisfactory. The annexed table indicates the results from the 4 other lots. The following prices were charged for feeds:— Maize 3 cents and kafir corn 3.5 cents per pound, hay $ 25 and silage $ 8 per ton. It is computed that the value of kafir corn as feed for lambs was only 2.9 cents per lb. while maize in the first lot in the table was worth nearly 3.5 cents.

Results of a 60-day lamb feeding experiment.

Kind of grain and hay fed	Initial weight per head	Average daily gain per head	Food consumed per pound gain			Feed cost per pound of gain	Profit (—) or loss (—) per lamb	Market grade
			Grain	Hay	Silage			
	Lb.	Lb.	Lb.	Lb.	Lb.	Cents	$

96 - **Goat Breeding in the Pastures of the West of the United States.** — CHAPLINE, W. R., in *United States Department of Agriculture, Bulletin* No. 749 35 pp., 12 pl., 2 fig. Washington, 1919. GOATS

This Bulletin constitutes a general treatise on goat breeding in pastures. Numerous problems relating to breeding in open grazing grounds are studied chiefly in connection with: — the nature of the pasture; methods of management which will permit of profitable production of goats without detriment to cattle and sheep or to timber reproduction; increase of revenue derived from goats, hair and meat by diminishing the losses caused by death; selection and care of the flocks.

The Bulletin ends with a summary of the more important points regarding management and breeding. The author recommends the division of the grazing ground into 3 parts for use in spring, in summer and autumn, and in winter respectively; the 2nd part should be at the highest elevations, the 3rd in the lowest and most sheltered parts; that portion of the pasture nearest to the sheds should be reserved for use in bad wea ther.

Over-grazing, which injures the pasture, tree growth, and the yield of the stock, should be avoided; an equal or higher revenue will be obtained by grazing, on the same area, a smaller number of selected goats instead of an excessive number of low grade animals.

The most economical and satisfactory results are obtained with flocks of about 1200 goats; it is best to graze separately goats in milk, dry goats, bucks, yearling and weaned kids. Goats should be put ont to graze for 4 or 5 hours in the cool of the morning and for a similar time in the evening; they should rest during the heat of the day. The bed grounds should be changed several times a year; it would be still better to graze the goats for short distances and to bed them at night where they happened to be in the evening; this allows of the grazing of a larger number and increases the production of goats, hair and meat while improving the pasture. The author recommends the Angora as the breed best suited to the western States of America where goats are kept chiefly for their hair and meat, and secondarily for milk and their skins. Young goats under 18 months of age are not yet suitable for breeding. One buck kept with the does at night and fed with a little grain as a supplementary ration will serve 50 or more does. In 1915 and 1916, for different flocks of Angora goats kept on open grazing grounds in New Mexico, the cost per annum of yearlings was from 95 cents to over $2 a head, exclusive of interest on the capital and the owner's labour; the average annual revenue for 2-year olds was about $2 a head; that for yearlings was slightly higher; the annual cost of pasturage of does and their kids varied from $1.62 to $2.78 per doe, and the average annual revenue per doe from $3 to over $5,50.

97 - **The Goat in Regions Devastated by the War.** — CRÉPIN J., in *Bulletin de la Société Nationale d'Acclimatation*, Year LXVII, No. 9, pp. 265-268, Paris, Sept., 1919.

The author has attempted to show that the general prejudice, in the agricultural world, against goats is very wrong; to show how profitable, from hygienic (very healthy milk consequent on the great resist-

ance of the goat to tuberculosis) and economic standpoints, is rational and well conceived rearing of goats (stall-feeding etc.) and to show what use can be made of the goat in the countries devastated by the war, no domestic animal being able to use, as it can, and to transform into produce, the meagre food which the uncultivated and sterile parts of the fighting zone can offer.

The author recommends for these regions the French Alpine goat for milk and the importation from Asia-Minor of herds of Angora goats to produce, in the north of France, the raw-material for the mohair cloth, already well known by the woollen manufacturers of those regions.

98 – **An Exceptional Case of Milk Secretion in the Goat and its Bearing on the Theories concerning Mammary Development.** — Hill, R. L., in *Journal of Dairy Science*, Vol. II, No. 1, pp. 19-27, 3 fig. Baltimore, 1919.

The author describes the case, noticed at the Maryland Agricultural Station, of a doe kid whose udder was well developed and whose teat yielded, on milking, an abundant flow of milk before she was 4 months old. A photogravure accompanying the article shows the kid sucking her mother while the kid herself is being milked.

This young animal's milk had the normal composition of goat's milk This kid was milked from time to time during about 6 months. The fact that relatively long intervals, even as long as 19 days, between milkings did not stop the secretion of milk proves that the lactation of this young kid differed from a normal lactation consequent on parturition. As this kid had not attained sexual maturity the phenomenon cannot be explained by any theory of mammary development, or of the appearance of milk secretion based on the development of the ovaries, corpus luteum, fœtus or placenta. The mammae of this kid had not been manipulated, had not been sucked and had not been subjected to any treatment to stimulate development or secretion. Possibly some other internal secretory gland may have a preponderant part in regulating the development and the activity of secretion by the mammary glands. Certain facts support the theory that the pituitary gland (*hypophysis cerebri*) might have that function.

PIGS

99 – **Pigs in Southern Albania.** — Massetti, C. in *L'Agricultura coloniale*, Year XII, No. 8, pp. 288-301, 3 figs. Florence, August 31, 1919.

In Albania the breeding of pigs is only of importance to the Christian part of the population, and has therefore spread among the Mirdites and the Malissores of northern Albania, especially in the province of Argirocastre, and in the Lower Greek Epirus.

The present breeds are certainly older than the Ottoman invasion, and very ancient. Two can be distinguished:— the indigenous mountain albanian ; the Epirus " gentile ". The habitat of the first is comprised by the region of Zem, the valley of the Zéta, and the Pindus mountains. They are often kept in herds, in open pasture, in the bush and woods of the mountains. The author thinks that they come from the ancient Illyrian mountain pigs, which have still remained pure. They present all the

characters of the breed which SANSON has named Iberian :— dolichomorphous type; skull dolichocephalous; snout very elongated; small tusks in the male; long legs, short body, not very fat; brown coat, very rarely black; bristles strong and thick, especially along the centre of the back, where they form a veritable mane, but not erectile like that of the wild boar. The male is especially wild, and runs away at the approach of a stranger. These animals are vigorous, robust, large eaters, easy to please; they are not early maturers, nor prolific; the sow generally farrows only once a year. By crossing this breed with other improved breeds very prolific progeny, with delicious flesh, result. A boar of the zootechnical station of Southern Albania weighed, at 9 months of age, 110 kg. The Albanian mountain breed resembles the robust Carpathian and Bavarian pig, from which, however, it differs by its bristles and by its somatic characters.

The Epirus breed is also included in the group of European origin, called by SANSON the " Iberian " breed. It is certainly a pig improved by the Greeks and by the Roumeliotes of Pindus. Its habitat comprises Central and Southern Albania, Western Macedonia, Pindus and Lower Epirus. It is a mesomorphous type, with dolichocephalic skull, pink or white skin, whitish or red pliable bristles, rare except on the dorsal line, where they are thick and bristling for a length of 7 or 8 cm. These animals fatten quickly and easily, they are less robust and less resistant than the preceeding breed; their character is gentle and quiet; they adapt themselves equally well to the damp climate of the plain and to the rigours of the high mountains.

BREEDING. — The young are kept in the sty until they are at least 4 months old; pasturage (acorns and grass) takes place from the end of the winter to the month of August in the low vallies. The animals are often left wthout keepers, and return alone from time to time to the sty; in summer the food given to them consists chiefly of cucurbitaceous plants (gourds, water-melons, melons). In winter they are shut up in the sties, made of branches or of wood, and mud, where they are fed with mashes of maize, sorgum, a little barley, beans and other legumes of inferior quality, cooked roots, cooked potatoes, bran and pollard, kitchen waste, greasy water, whey, all seasoned with salt. Covering usually begins in May or June; parturition in September and October. The sows of the mountain breed bear from 3 to 5 young pigs per litter, those of the Epirus breed 4 to 7. The sow nurses the young from 2 to 2 ½ months. When the number of the young pigs is greater than usual (the author has noticed 11 young ones in one litter) a supplement of goat's milk is distributed after the 15th day. Females predominate in the Epirus breed, and males in the mountain breed. Weaning begins on the 60th day and is finished by the 70th. At 3 months old the boars are selected, and the other young pigs are castrated.

Breeding is generally done with animals of the same kind, but there are Albano-Epirus half-breeds in Southern Albania, Albano-Mongolicza and Albano-Choumadia, half-breeds on the frontiers of Serbia and Montenegro. Besides the pigs already described a very much improved breed com-

monly called "Maltese", which has all the characters of the Apulian breed, has spread especially in Corfu and in the Lower Epirus.

The fattened animal weighs fom 140 to 160 kg. It is slaughtered by cutting the throat, while the half-wild pigs of the mountain breed are shot in the head.

In general, in the Epirus pigs, the lard and fat represent 1/4 of the total weight of the bled animal, against 3/4 for the meat, bones and intestines.

A castrated Epirus pig of 9 months of age, weighing 105.5 kg, gave after slaughter: — head 9.1 kg.; right half 39 kg.; left half 38.85 kg.; heart, lungs, windpipe 1.1 kg.; intestines, stomach, feet 10.2 kg.; bristles 0.547 kg.; blood and waste (by deduction) 6.703 kg. The flesh is smoked, preserved with salt or eaten fresh; in Albania neither small nor large sausages are made, and the ham industry is unknown; the bristles are not used for making brushes; the skins are tanned for the manufacture of saddlery; there are 3 tanneries at Argirocastre. A certain quantity of lard is exported from Albania.

Diseases. The following diseases have been reported: — Swine fever; anthrax; foot and mouth disease; Sarcoptic mange; measles; echinococcus; the 2 last are common in the low marshy zone and cause great damage to the herds there.

100 – **Inheritance Investigations in Swine.** — *Kansas Agricultural Experiment Station Report for the Year* 1918, pp. 41-42. Manhattan, Kansas, 1919.

Cross-breeding experiments with swine gave the following results: — 1) The wide forehead (Berkshire) is dominant with respect to the medium forehead (Duroc-Jersey) and to the narrow forehead (Tamworth, wild hog); 2) the straight face (Tamworth, wild hog) is dominant with respect to the dished face (Berkshire); 3) the long face (Tamworth) is completely dominant to the short face (Berkshire); 3) the erect ear (Berkshire) is dominant to the drooping ear (Duroc-Jersey).

101 – **The Feeding Value of Skim Milk for Swine.** — Norton, H. W., Jr., in: I. — *Michigan Agricultural Experiment Station, Quarterly Bulletin* Vol. I, No. 1, pp. 17-18, East Lansing, 1918. — II. *Michigan Agricultural Experiment Station, Special Bulletin* No. 92, 9 pp., 1918.

I. — A summary of the results of a large number of feeding trials by different experiment stations throughout the United States was made to determine the value of skim milk as a supplement to maize and other cereal grains when fed to pigs. It is pointed out that 415 pigs fed on cereal grains only made an average gain of 100 lb. from 486.5 lb. of grain and that 325 pigs fed on cereal grains supplemented by skim milk made an average gain of 100 lb. from 266.9 lb. of grain and 785.1 lb. of skim milk. This indicates that 100 lb. of skim milk replaced 28 lb. of grain. Calculated on the basis of $ 50 to $ 80 per ton for the different grains used, which included maize, wheat, rye and barley, the value of the skim milk ranged from 0.7 to 1.2 cents per pound. Much greater returns were got from the skim milk when 2 to 3 lb. of milk was fed per pound of grain than when the milk was fed in larger quantities.

II. — This bulletin is an amplification of the preceding one. It is computed that a pound of any of the following supplements would replace the designated amount of grain : skim milk 0.28 lb. ; tankage 2.53 lb. middlings 1.05 lb. ; linseed meal 2.62 lb. ; soy-bean meal 2 lbs. Buttermilk is considered to be equal in feeding value to skim milk, and whey about half as efficient.

102 – **A Comparison of Velvet Bean Meal Tankage and Soya Bean Meal as Supplements to Maize Meal in Feeding Hogs.** — Good, E. S., and Mann, L. B., in *Kentucky Agricultural Experiment Station Circular* 20, 4 pp. Lexington, 1918.

A lot of 8 Duroc-Jersey and Berkshire shotes, each weighing originally about 125 lb., was fed on maize meal and velvet bean-and-hull meal (5 : 1), another on maize meal and tankage (9 : 1) and a third on maize meal and soya bean meal (7 : 1) for 89 days. The average daily gains were, respectively, 0.8, 1.52 and 1.42 lb. per pig, and the corresponding amounts of feed consumed per pound of gain were 6.5, 4.2 and 4.5 lb. Although the velvet beans were much cheaper than tankage or soya beans, they were fed at a distinct loss. The velvet bean ration had a wider nutritive ratio than the others, but it was impracticable to increase the proportion of velvet beans since the mixture as it stood was unpalatable, due presumably to the high crude fibre content. It is suggested that a velvet bean meal made from the kernels only would be a more useful feeding stuff to place on the market.

AVICULTURE

103 – **The Choice of Laying Hens.** — Andrew, R. C., in *Utility Poultry Journal*, Vol. IV, No. 9 pp. 2-5, 1 diagr. Harper Adams Agricultural College, Newport, Salop, 1919.

The improvement of poultry stock can be obtained at small cost and with very little trouble by discarding all the defective birds at the right time, so as to keep only the best.

Age at which the choice of hens to keep and those to discard should be made. — In the egg-laying competitions which were held at Harper Adams Agricultural College, Newport, Salop, England, the following data respectively were obtained in the trials of 1915 to 1917 for 252 hens in the 1st year of laying and for an equal number of hens in the 2nd year : — Number of eggs laid in a year by the 252 hens : 43 968 and 28 137 ; average number of eggs per pen of 6 hens : 1046.8 and 670 average number per hen : 177.4 and 112 ; that is to say the hens, in the 2nd year of laying only produced about 60% of the number of eggs laid in the 1et year. In egg laying competitions held in Australia the comparison has been carried up to the 3rd year with the following results :—

White Leghorn breed : — 1st year 209 eggs ; 2nd year 149 ; 3rd year 123 ; Black Orpington breed : — respectively 202, 156 and 118. Except in the case of exceptional merit, hens should, therefore, not be kept after the second year of laying.

Time of the year at which bad laying hens should be discarded. — Summer appears to be better than winter for the selection. The egg production by successive periods of 4 weeks each, dating from the commencement of laying, (13 periods for hens in their 1st year of laying and 12 for those in their 2nd year of laying, determined at Newport, reached its minimum in

the 3rd of these periods, its maximum about the 7th. and decreased rapidly after the 9th, which ended about the middle of June.

The least profitable time for the selection of hens to be discarded is the beginning of spring, for then the cost of keeping the hens during the unproductive winter has been incurred and by not getting rid of them until a little later they would lay eggs which would cover the expense.

The poultry-keeper often makes the time of selection depend on the amount of food produced on the farm and available during different seasons of the year ; but, it is never profitable to keep a hen which does not repay the cost of her food. To ascertain whether the eggs laid cover the cost of the food consumed by the flock of hens, the following method may be useful : — Divide the price of 100 lb. of food by the price of one dozen eggs and multiply the quotient by 3 ; the result gives the number of eggs which should be laid daily by 100 hens to pay for the food. This formula is based on the assumption that each hen consumes 4 ounces of purchased food per day.

When a hen is in laying condition the pubic bones are relaxed, which increases :— (1) The distance between these bones ; (2) the distance between the hinder end of the breast bone and these bones. Measurements made at Newport have proved that the distance between the pubic bones is on the average 1.3 inches for hens in laying condition and 8 in. in nonlaying condition, and that the distance between the hinder end of the sternum and the pubic bones for White Leghorns (light breed) and White Wyandottes (heavy breed), respectivelyis : — hens in laying condition 3.1 inches and 3.6 inches ; hens not in laying condition 2.1 inches and 3.29 inches. These differences are sufficiently large to be perceptible, the former when measured by the finger tips and the latter by finger widths. It is better to use fingers than an instrument because by so doing it is possible to feel the texture of the skin.

104 – **The Effect of Date of Hatching on Egg Production.** — Buss, W. J., in *Monthly Bulletin of the Ohio Agricultural Experiment Station*, Vol. IV, No. 3, pp. 69-83, 3 figs. Wooster, Ohio, 1919.

Two years' egg production records are presented of three lots of Single Comb White Leghorns, the first hatched on February 22, 1916 and the others 8 and 16 weeks later respectively. At the beginning, each lot consisted of 30 pullets. While laying they had constant access to a dry mash of ground maize, bran and meat scrap (2 : 1 : 2) and were fed on shelled maize and wheat (3 : 1) twice daily to the extent of double the mash consumption. The following table summarises the chief results : —

A table is given which shows the egg production of each lot by 4 week periods during the first year as percentages of the maximum, an egg a day per bird. During August, September and October this percentage in the case of the early hatched lot varied from 26 to 47, but from November 1 to January 24 it was throughout between 6 and 7. During the latter period the pullets went through a moult resembling that of year-old hens. The production of the April-hatched lot varied from 18 to 10 per cent. dur-

ing November, December and January, and showed no pronounced slump until the following November. In all three lots the highest production of any period occurred at the same time, between March 22 and April 18.

Egg record of 3 lots of White Leghorns hatched at different periods in the spring.

Date hatched	Laying record began	Pullet year				Second year			
		Laying period	Average size of flock	No. of eggs per pullet	Feed per dozen eggs	Laying period	Average size of flock	No. of eggs per hen	Feed per dozen eggs
1916	1916	Days			Lb.	Days			Lb.
Feb. 22	Aug. 10	448	29.0	166.9	2.726	364	26.7	109.9	3.098
Apr. 20	Nov. 2	392	28.4	156.4	2.635	364	24.8	119.5	2.993
June 13	Dec. 28	336	29.5	144.0	2.791	364	26.5	118.6	2.658

CONCLUSION. — There is practically nothing to the gained by hatching Leghorn eggs very early (February 22 in the latitude of Wooster, Ohio, U. S. A.), considering the high price which the same eggs would bring on the market, the low fertility, the long period the chicks must be kept in the brooder and the drop in production of the resulting pullets during the winter months.

VARIOUS ANIMALS

105 – **Deer in New-Caledonia; Utilisation of their Flesh by Canning.** — *Bulletin de l'Office colonial*, Year XII, No. 140-141, pp. 533. Paris-Melun. Aug.-Sept., 1919.

Deer have become an apparently irremediable nuisance in New Caledonia. Near St Vincent they are met with in numerous herds, and often in groups of over a hundred. They ravage and destroy everything. It is impossible to keep them out by fencing, because they leap the highest barriers. From Nouméa to Bourail they infest the whole region.

The Pacific Packing Co., wheh has a preserving factory at Neméara, is attempting an experiment which will be welcomed by all, and more particularly by colonists and cattle-breeders. This is the preservation of venison. This company buys deer, unskinned and disembóweled with care, at a price of 25 fr. a head and it organises a rapid transport service to the factory by motor lorry. By this fortunate idea, hunting will become a paying business. Everyone will use it to rid the colony of this harmful game.

FARM ENGINEERING

AGRICULTURAL MACHINERY AND IMPLEMENTS

106 – **Team Work.** — RINGELMANN, in *Comptes rendus des séances de l'Académie d'Agriculture*, Vol. V, No. 29, pp. 781-788. Paris Oct. 1, 1919.

In order to study the economic conditions of employing a mechanical cultural apparatus on various typical farms, it is necessary to know

the monthly distribution of the daily work of teams on these farms. But not being able to find this information, which is, after all, in the province of rural economy, the author attempted the following preliminary estimate based on some observations, the general applicability of which is contingent on circumstances.

Meteorological returns show, after many years of observation, the average number of days of rain, snow, frost, etc., per month, and for various stations. On snowy days animals do not work in the fields, on frosty days waggons are affected ; but during at least about one third of the days shown as rainy by the meteorologists work on the land is continued.

On the basis of the figures relating to Paris the author thus found 228 days on which teams could work in the fields, with a maximum of 21 days in August, and a minimum of 15 in November and December.

Observations, made on several farms, show that the working hours of teams in the fields may be represented roughly by the time between the rising and setting of the sun, diminished by at least 3 hours. (There are meals, snacks, the time taken in coming and going from the stables to the fields, etc., but on the other hand the start is often made before sunrise, and the return after the astronomical hour of sunset). Astronomical almanacks give the hours of the rising and setting of the sun for every day in the year. The calculation may be made on the hours of the 15th day of each month.

For the region of Paris 2099 hours of work were calculated to be possible for a team in the fields, with a maximum of 260 hours during the months of June and July and a minimum of 75 hours during December.

The author has given the details of these figures, with a graphic representation, in "*Culture mécanique*" (Vol. VI, p. 152, Librairie agricole de la Maison Rustique, 26, rue Jacob, Paris).

The preceding calculations show that it would be possible to represent teams according to the number of days and hours of work, but it does not follow that the farm would make use of these days and hours.

To do it properly it would be necessary to have during several years, in different farms, suitably chosen, a man whose main duty would be to keep count of the days and hours during which teams were used, as well as the work carried out.

One of the correspondents of the Academy, M. Henry Girard, having become acquainted with these calculations of the author, let him know that he had kept count, day by day of all the work done by his workmen and his farm at Bertrandfosse, at Plailly, the south of the Department of the Oise. He entrusted him with three diaries, consisting of valuable documents, on the subject of which the author gives the following general preliminary information.

The estate of Bertrandfosse included 253.58 ha. in 1911 and 1912 and 271.26 in 1913. The cultivated area (in hectares) has fluctuated in the following manner. — Wheat, 56.3 to 63.0 — Oats, 67.9 to 74 — Beets, 32.7 to 28.0 — Potatoes, 3.7 to 2.7 — Carrots and turnips, 2.5 to 6.5 — Lucern, sainfoin and Black Medick (*Medicago lupulina*) 18.1 to 22.3 — Forage crops, 12. to 11.0 — Meadows for hay 20.1 to 17.8 — Pasture grass, 40.0 to 46.0.

The minimum areas to cultivate, at least once each year, for the following rotations : — wheat, oats, beetrrot, potatoes, carrots and turnips, represent 163 and 174 hectares.

During the years 1911-1912-1913, the total number of draught animals was 17 agricultural horses (2 teams of 4 horses, 3 teams of 3 horses) and 18 strong oxen (3 teams of 6 oxen).

It would be much too long to detail the daily statement, during 3 years, of the day's work of the horses and oxen attached to different work ; however the outhor gives the limits of the number of animals employed each month (average of 3 years.)

Horses. — In January 10 horses at least worked per day, and at most 16 ; in February they varied from 11 to 16 : March, 13 to 17 ; April, 13 to 17 ; May, 12 to 16 ; June, 11 to 16 ; July, 12 to 15 ; August, 12 to 15 ; September, 12 to 16 ; October, 14 to 17 ; November, 12 to 17 ; December, 12 to 17.

The total number of draught horses was fully used only during certain days of the months of March, April, October, November and December. The minimum is shown in January.

Oxen. — In January at least 6 oxen and at most 17, worked per day ; in February, 7 to 17 ; March, 11 to 18 ; April, 13 to 18 ; May, 6 to 16 ; 16 ; June, 2 to 10 ; July, 4 to 12 ; August, 6 to 12 ; September, 8 to 14 ; October, 11 to 17 ; November, 10 to 17 ; December, 4 to 16.

The total number of draught oxen was used only on certain days of the months of March and April ; the minimum is shown in June.

Labour. — On an average for the 3 years, 15 men, 5 women and, as casual labour, 8 Bretons, were employed per day.

Team work. — To sum up the monthly abstracts of the working days, which can be done in graphic form, the author adds together the average working days of horses and oxen for the 3 years, comparing them with the working days which were usable, according to the number of horses, oxen, and working days (that is not counting Sundays and holidays), and giving the monthly coefficients of utilisation. He thus obtained the following Table (see first Table page 102).

Without any agreement with the number of usable working days, the two maxima of utilisation are shown in April and in October, the minima in February and in June.

Of the 10710 working days usable annually, the teams were only used during 7782 working days ; the average annual coefficient of utilisation is 72 % (it varies from 49% in June to 91 %, in April); 2928 working days of teams have been unused per year, during which the animals were fed ; this question is important to-day for the heavy draught horses, which cost about 15 fr. a day at Bertrandfosse ; one working day of an unemployed horse constitutes a loss, while the ox, who remains in its stall, takes profit every day from the food distributed to him.

In the second table are brought together the absolute and relative numbers of day's work of teams for the principal work of the heaviest worked months, April and October (average of 3 years).

Month	Number of working days of the teams		Coefficient
	usable	used	of utilisation per 100
January	875	661.0	75.5
February	840	583.9	69.5
March	910	781.4	85.8
April	875	796.5	91.0
May	875	673.7	76.9
June	875	430.9	49.2
July	910	461.9	50.7
August	980	629.0	64.1
September	910	662.7	72.8
October	945	823.7	87.1
November	840	657.2	78.2
December	875	620.5	70.9
Totals	**10 710**	**7 782.5**	*gen. average* **72.6**

Work	April		October	
	Number of working days	Proportion	Number of working days	Proportion
Ploughing	227	28.6	265	32.3
Harrowing, rolling, scarifying	298	37.5	24	2.9
Spreading of manure and sowing	74	9.3	59	7.1
Carting	172	21.6	353	42.9
Various	25	3.0	122	14.8
Totals	**796**	**100.0**	**823**	**100.0**

Thus out of 100 working days of the teams, ploughing only uses 28 and 32, while harrowing, rolling, scarifying and especially carting in October, occupy the greatest number of draught animals.

On many farms, teams are insufficient for ploughing and preparatory work, because they are used for carting which cannot be put off.

This confirms what large farmers near St. Cyr and Brétigny recently explained to the author; they declared that the draught animals, which they are obliged to keep on the farm, would have been fully sufficient for ploughing if they had not been reduced by the number employed on light work and for carting.

The author hopes to continue the inquiry for, if what has been stated is confirmed, there would be, in France at least, a new outlook for many mechanical agricultural machines, especially those suited to light work, the drawing of harrows, rollers, seedling-machines and manure spreaders, reapers and binders, and particularly carting on the farm.

Having had the good fortune to have the daily statements of M. HENRY GIRARD'S farm, the author continued to make an abstract of all the work done there, with or without teams. This is certainly a work of rural economy, the results of which — interesting to rural engineering, applicable to farms like Bertrandfosse — cannot be too generalised; but their study would induce other people perhaps to make similar statements, which would be very interesting to analyse (1).

M. PETIT, present at the meeting of the Academy, confirms the observation of M. RINGELMANN on the following points —: (1) April and October are the two months during which teams are insufficient on all farms; (2) The substitution of oxen for horses is to be recommended from an economic standpoint, because resting oxen cost less to feed than horses. But farmers look forward, mainly, to use tractors for the heaviest work, which tires the teams enormously.

107 – **On the Investigation of Resistance to wear of Parts of Agricultural Machines.** — RINGELMANN, M., in *Comptes rendus de l'Académie des Sciences*. Vol. CLXIX, No. 18, pp. 807-809. Paris, Nov. 3, 1919.

Metal parts in the construction of agricultural machinery are subjected to different strains (extension, compression, flexion, torsion), which for the most part are fairly easily calculated. The problem becomes more difficult when we have to consider the incessant action of shocks, developping momentary high forces, which tend to impair or deform the parts.

The author was entrusted by the Society for the Encouragement of National Industry with investigations on the nature of metals employed in the construction of agricultural machinery (tests of hardness and brittleness completed by metallographic tests, thermal treatments and chemical analyses). For many of the working parts, it is specially necessary to consider their resistance to wear by friction in the ground according to the various conditions of work.

A simple process consists of trying each kind of part, made of different metals, working under different loads in the fields; each part is attached to a special waggon, drawn by a team, and provided with an apparatus for registering the distance travelled.

This process is very long, for certain working parts are worn out after a journey of over 2000 km., and it is necessary to make them travel at least 100 to 600 km. in the fields so that a conclusion on each test may be possible. Moreover, for the same parts, it is necessary to carry out comparative trials in various kinds of soil, in different states of humidity and consequently of tenacity.

As these direct trials in the fields are very long, very costly, and consequently inapplicable, the author has got round the difficulty in the following manner :—

(1) Statistical statements on the economy of working the soil, cultivation, and harvesting, have been made already in certain places. Particularly the "Office of Farm Management" of the Department of Agriculture of the United States, has published some in 1916, which concern the western part of the State of New York; for this see *R.*, March 1917, No. 276. (*Ed.*)

The parts are revolved through a given soil, by a large axle, driven at the desired speed by an electric motor; a counter registers the distance traversed, which may be as many kilometres as are desired. In these conditions, for a given kind of working part, after a certain course L, the wear a is noted.

A *standard* of homogenous metal, wearing very rapidly, of the same dimensions as the parts tested, indicates on the testing apparatus a wear A, for a much reduced course l.

To obtain the proportion between the amount of wear of parts in different soils, the standard parts are then made to pass through a course l^1, in the fields, of which the soils are of various kinds, which shows an amount of wear A^1.

It is then easy to compare the amount of wear A^1 and A with a and to deduce from them the journeys L, which each kind of metal can stand in different soils before the part is worn out. With this method, the tests in the fields are made in a single day.

Finally for each kind of working part, shapes, dimensions, and loads, we must work with different metals as physical constants, so as to be able to indicate in each case the course L^1, over which we can in practice use the working parts of machines intended for cultivating the soil.

The same general experimental principle with the use of a suitable standard of rapid wear can be applied to the study of the resistance to wear of different parts used in the construction of agricultural machinery.

108 – **Trial of Three-Furrow Ploughs for Mecanical Ploughing in Italy.** — AMBROSINI, I., in *L'Italia agricola*, year 56, No. 5, pp. 149-150. Piacenza, May 15, 1919.

The majority of trials of mecanical ploughing carried out up to date postulated the use of a constant type of plough, and served to judge the tractor. The author wished, on the contrary, to judge the ploughs which are most generally used, the motive force remaining constant.

The following ploughs were put to the test: — (1) THREE-FURROW PLOUGHS: — (*a*) *with disc coulters.* — Parlin 12", weight 440 kg. — Case 12", 372 kg. — Oliver 12", 464 kg. — Gran Detour 12", 419 kg. — Miliani, 405 kg. (*b*) *ordinary coulters.* Miliani 384 kg. — (2) TWO-FURROW PLOUGHS. Parlin 12", 356 kg.

Trials ware carefully made in two soils, A and B, both of very uniform texture, and the second 25 % lighter than the first. The results are shown in the following table: —

The work done in the two soils with 3-furrow ploughs gave good results but that done with the 2-furrow plough was insufficient.

The 3-furrow Gran Detour plough requires enormous tractive force, which should be partly attibuted to the fact of having taken a ploughing width less than that of the other triple ploughs. The 3 coulters and shares had equal work; the right mouldboard only had its work lightened. But of the active parts of the plough, it is not the mouldboard which meets the greatest resistance. It allows that, when working with a multiple plough, it is not very advantageous to keep within the width of the plough, that

Types of ploughs.	Soil *A*					Soil *B*				
	Depth of ploughing	Breadth of ploughing	Average section of furrow	Average effort	Average effort per sq. dm.	Depth of ploughing	Breadth of ploughing	Average section of furrow	Average effort	Average effort per sq. dm.
	cm.	cm.	sq.dm.	kg.	kg.	cm.	cm.	sq.dm.	kg.	kg.
1) 3-FURROW PLOUGHS										
a) *with disc coulters:* —										
Gran Detour (20 cm)	21 to 22	77 to 81	16.05	1204	75.0	21 to 23	76 to 81	16.97	1132	66.7
Oliver . . . (20 cm)	20 to 22	102to155	21.63	1128	52.1	—	—	—	—	—
Little Genius (20 cm)	21 to 22	93 to 100	20.26	1000	49.3	21 to 23	84 to 93	19.02	683	35.9
Case . . . . (20 cm)	22 to 24	94 to 99	21.15	1198	56.6	21 to 23	85 to 93	19.88	750	37.7
Miliani	24 to 25	87 to 94	22.27	1270	57.0	21 to 23	87 to 96	19.92	806	40.4
b) *with ordinary coulters:*										
Miliani	22 to 23	88 to 96	26.29	1264	62.3	21 to 23	89 to 92	19.56	804	46.0
2) 2-FURROW PLOUGHS										
Parlin. . . . (25 cm)	24 to 27	54 to 62	13.93	1176	84.4	—	—	—	—	—

is to say to take little earth with the right hand share; it is by making all the shares work fully that the greatest output is obtained; otherwise one share of the plough should be taken away, reducing it from a triple to a double plough.

The Oliver, Little Genius, and Case ploughs requered almost the same pull, but Little Genius beat all the others. The lightness of traction was constant in this plough which weighed, however, more than all the others, except the Oliver, from which it differs slightly. Moreover it is known that the weight of the 3-furrow plough has very little influence on the traction.

The replacing of ordinary coulters by disc coulters in the Milani plough allows an economy of about 10 % of energy.

The trial with the Parlin 2-furrow plough shows that, when it is wished to work deeper with a plough than the depth for which it was constructed, there is considerable and rapid loss in output (while the Parlin plough is constructed for ploughing to a depth of 20 cm, it was desired to attain with the 2-furrow plough an average of 25 cm). Moreover ploughing with a 2-furrow plough in proportion to the unit of section of the furrow, is always less advantageous than ploughing with a triple plough.

TILLAGE MACHINES, AND IMPLEMENTS. *Canada*: 191784 Combined harrow and cultivator; 191791 Cultivator; 191798 Steam plough combined with manure spreader; 191825 Apparatus for filling up ditches; 192052 Harrow; 192178 Harrow accessory for plough; 192378 Spiral harrow.

United States: 1309831 Garden cultivator; 1309920 Subsoil plough; 1211212 Clod-breaking roller and cultivator combined; 1312669 Cultivator with insecticide distributor; 1313242 Cultivator; 1314292 Accessory for disc harrow.

France: 493624 Improvements in motor'tractor ploughs; 493752 Wheel plough; 493919 Plough with multiple rotating share; 494025 Device for the automatic raising of tools in cultivating machines; 495070 Machine for tilling orchards; 494087 Orchard plough; 494274 Garden plough; 494884 Mecanical traction balance plough; 494959 Steam tractor apparatus for ploughing vineyards; 495268 Arrangement for transmitting electric power to a cultivation set, working on the 2 windlass system; 495329 Machine for earthing-up vjnes; 495330 Root pruning plough (principally for vines); 495341 Improvements to motor ploughs; 496538 Motor earther for cultivation of vine; 496569 Self-acting anchorage system for ploughing with a two-way electric windlass.

New Zealand: 40473 Harrow with scarifying teeth.

United Kingdom.: 128953 Motor cultivator; 130176 Motor plough with multiple turning mould-board; 130437 Raising handle for ploughs, cultivators etc.; 130759 Apparatus for lowering and raising successively the shares of a multiple plough, so as to commence and end uniformly the furrows at the headlands; 131447 Disc harrow, 131715 Disc harrow with back wheels which can be regulated in height; 132550 Cultural apparatus with jointed frame changeable in shape.

MANURES AND MANURE DISTRIBUTORS. *Canada*; 191798 Manure distributor combined with a steam plough:

United States: 1310544 - 1313427 Manure Spreaders; 1313116 Gearing for manure spreader; 1313297 Manure loader; 1313495 — 1313653 Manure distributors.

France.: 496514 Process and plant for preparing dried blood' especially applicable as manure.

India. 4716 Process for making soluble potassic salts by means of felspar.

New Zealand.: 41948 Phosphatic manure (obtained by the calcination of natural phosphates mixed with other ingredients in a rotary kiln).

United Kingdom: 130963. Manure obtained by heating minerals or ground potassic rocks (leucite, volcanic ashes, felspar, granite, etc.) with carbide of calcium, in a current of nitrogen; 131493 Nitrate of lime produced by bacterial oxidation of cyanamide of calcium.

DRILLS AND SEEDING MACHINES. — *United States*: 1311010 Gea-

ring for a maize sower; 1311427 Method of sowing aud apparatus relating to it; 1312214 Potato planters; 1312817 Hand sower for maize and leguminous seeds; 132189 Distributing mechanism for potato planter.

New Zealand: 40570 Seeder.

United Kingdom: 128853 Potato planter; 130185-131097 Machines for planting potatoes.

VARIOUS CULTURAL OPERATIONS. — *United States:* 1313310 Machine for destroying weeds; 14715-1313637-1313735 Straw spreaders; 1314122 Machine for rooting out couch-grass; 1314307 Cotton chopper.

France: 495329 Vine earther; 496538 Motor earther for cultivation of vines.

CONTROL OF DISEASES AND PESTS OF PLANTS. — *United States:* 1312969 Distributor of insecticides combined with a cultivator; 1313310 Machine for destroying weeds; 1314122 Machine for exterminating couch-grass.

France: 494077 Soluble insecticidal powder (sulphate of copper 32 kg. + neutral sulphate of soda 36 kg. + carbonate of ammonia 24 kg.); 494351 Improvements to spraying machines; 494959 Devices for sulphating and sulphuring combined with a tractor apparatus for working vineyards.

India: 4856 Process for destroying insects injurious to tea, etc.

United Kingdom: 132214 Insecticidal product destined to destroy the "shot hole borer" (*Xyleborus fornicatus* Eichh), a beetle injurious to tea, coffee, and cocoa plants (mixture of soft soap, resin, and fish oil, which is diluted with water for application by hand, in the form of jelly, to the trees attacked).

REAPERS, MOWERS AND OTHER HARVESTING MACHINES. — *Canada:* 192188-192243-192328-192388 Reapers; 192408 Hay-rake; 192612 Maize harvester.

United States: 1210133-1212432 Maize harvesters; 1211201 Machine for pulling up and cutting maize stalks; 1311407 Machine for harvesting hemp, 1312010 Machine for picking cotton; 1213880 Rotary hay-rake with lateral discharge.

France: 393749 Apparatus for sharpening scythes; 496311 Device for hand-baler; 496316 Improvements to mowing machines.

New Zealand: 40743 Machine for mowing flax.

United Kingdom: 129118 Mower; 131824 Hay-making machine.

Switzerland: 82556 Sheaf-binder; 82557-82737 Apparatus for gathering fruit; 83073 Apparatus for forging scythes.

MACHINES FOR LIFTING ROOT-CROPS. — *Canada:* 191821 Potato lifter.

United States: 1309617 Beet lifter; 1309940-1310335 Beet harvesters; 1310849 Beet topper; 131305 Machine for harvesting groundnuts; 1314270 Potato digger.

United Kingdom: 131606 Potato lifter.

THRESHING MACHINES. — *Canada:* 192082 Machine for shelling peas; 193135 Thresher for threshing machines.

United States: 1309910 Machine for threshing leguminous seed

plants ; 1310759 Machine for sorting and cleaning grain and seeds ; 1314353 Machines for husking maize.

New Zealand: 40056 Threshing machine.

Switzerland: 82555 Machine for husking maize ; 82.736 Apparatus for separating the seeds of cereals from the seeds of weeds.

Machines and Implements for the Preparation and Storage of Crops. — *Canada*: 192588 Mechanism for compressing silage.

United States: 14704 Machines for cutting potatoes ; 14705 Maize elevator ; 1309861 Machine for gathering and loading hay ; 1310187 1312342 Hay loaders ; 1311451 Machine for making hay-ricks ; 1311742 Apparatus for retting hemp ; 1312066 Machine for transporting litter ; 1312271 Arrangement for keeping ears of maize hung up for seed ; 1312832 Machine for weighing grain.

New Zealand: 40259 Machine for retting flax ; 40412 Machine for retting and scutching flax.

United Kingdom: 131735 Silo.

Switzerland: 83074 Apparatus for cutting vegetables ; 83247 Silo for sweet silage ; 82554 Apparatus for cutting hay heaped up in barns.

Forestry. — *Switzerland*: 73443 Felling and logging machine.

Traction and Steering of Agricultural Machines. — *United States*: 1310604 Tractor.

France ; 494166 Agricultural-viticultural tractor ; 494959 Steam tractor apparatus for vine cultivation ; 495042 Agricultural tractor ; 495268 Arrangement for transmitting electric power to a cultivation set working on the 2 windlass system ; 496121 Industrial and agricultural tractor with 4 driving and steering wheels ; 496522 Tractor for agricultural machines especially for ploughs ; 496569 Self-acting anchorage system for ploughing with two-way electric windlass.

United-Kingdom: 131466 System for coupling agricultural machines to a tractor.

Switzerland: 82553 Propelling device enabling agricultural tractors to get a better purchase on the soil.

Feeding and Housing of Livestock. — *France*: 493807 Safety device for simultaneaously letting out all the cattle from a shippon ; 495328 Improved food for horses, oxen and sheep.

New Zealand: 39726 Arrangement for preventing cattle and horses from jumping.

Poultry Keeping. — *France*: 494086 Temperature regulator for incubators.

United Kingdom: 129838 Granulated food for poultry (prepared with a sticky mash of ground clover, boiled potatoes, and water, which is divided, dried, roasted, and finally impregnated with fish oil).

Bee-keeping. — *France*: 493805 Hive (round, made of rye straw, very low interchangeable blocks, and very light interior frames of variable size ; suitable covers separate the blocks ; the whole is securely fastened with hooks and eyes).

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — *United Kingdom*: 132566 Various uses of groundnuts.

DAIRYING. — *New Zealand*: 41475 Milking machine worked by electricity; 41684 Milking machine; 41684 Accessory for milking machine used for taking out samples of milk for weighing them.

United Kingdom: 128544 Artificial milk (obtained by mixing an emulsion of a fat or an oil with skim milk); 128845-130189 Apparatus for sterilising milk; 129105 System of closing churns and other milkreceptacles; 129561 Cheese press.

RURAL ECONOMICS.

111 – **Farm Management Demonstrations in New York State, 1919.**— SCOVILLE G., P., in *Journal of Farm Economics*, Vol. I, No. 2, pp. 44-45. Lancaster Pa., Sept., 1919.

Farm management demonstration work has been carried out in the Niagara county in the Western New York fruit region for the last seven years. The farm bureau committee arranged for a meeting in each of the fourteen school districts in the town. The farmers were asked to bring to the meetings any records they had of their farm expenses and receipts.

At the meeting each farmer attempted to fill out a labour income blank for his farm. Ninety-eight such records were started and generally completed at these meetings; 63 other records were secured through farm calls.

The total number of records taken in Niagara county during the last 6 years was 626.

Since the farm management demonstration work started there have been 4770 labour income records taken in 49 areas in New York State. The tendency is now to reduce the number of areas and to increase the number of records per area. In the northern part of Livingston County, 724 records were taken in the spring of 1919, and the same area was taken ten years ago.

No data have been collected concerning the accounts kept by the farmers; less than 10 per cent. of these farmers, probably, take an annual inventory, but nearly 90 per cent. of them keep some records of their expenses and receipts.

The county agents in New York State have asked for over 4000 inventory books and as many more cash books during the last winter and spring. These books simply furnish a place for taking an inventory and recording receipts and expenses. Farm amounting is of little value without analysing the farm business, therefore in this demonstration work *analysing* rather than recording is insisted on.

112 – **Income Tax and the Farm Management Demonstration Work in Iowa.** — THOMPSON, S. H., in *Journal of Farm Economics*, Vol. I, No. 2, pp. 45-47. Lancaster, Pa., Sept., 1919.

The Income Tax Act has stimulated thousands of farmers in the keeping of farm records. While the Farm Management Demonstrators in Iowa have been consistently urging the need of keeping records in complying with income tax requirements, they have recognised that the income-tax

matter was not an end in itself but merely a method of approach in the study of the farm as a business. Farm officers were deluged with appeals for help ; in too many cases, however, it was not possible to aid the men asking for help in emplying with income tax requirements. Of 76 Iowa farm bureaus that have reported to date, all but three worked with the income tax. The 73 who included the work on income tax and farm records as a project reached 8896 farms.

Forty four bureaus worked only with individuals, while twenty - nine assisted both individual and groups. The bureaus that worked with individuals alone reached on the average 89 each, while those that worked with groups reached one hundred and seventy each. More than 60 000 Iowa farmers, on an average of six hundred per county, filed returns this year. Considering the size of the work ahead of the farm bureau the advantage of the group method of work becomes apparent. Meetings held in different parts of the country attended by one hundred farmers would help in solving the problem. These farmers, with the help of the Farm Management Demonstrator, and of the county Agent could be assembled for income - tax instruction and analyses of their farm business. The best time for conducting this work is between December 1 and March 15.

During the present fiscal year Iowa hopes to start a very thorough farm management campaign. As a prelnde it is planned to hold a series of district conferences of country agents where plans for county projects will be fully discussed. It is recognised that varying conditions in the counties will prevent the use of a uniform project. It is contemplated that each county will be given from two to five days of a farm management demonstrator's time for further assistance of the agents through local meetings.

The agent will then personally, or through local demonstrators, extend the work until every township has been given an opportunity to receive instruction on labour income records, cost accounts and income tax.

113 – **Capital Required and Profit to be made on a Farm in West Africa.** — DUMONT, P., in *La Vie agricole et rurale* (from a paper by M. FALLON on Agriculture in the Belgian Congo), Year IX, No. 9, pp. 159-162. Paris, 1st March 1, 1919.

Owing to the rush to colonial agriculture, which will doubtless be made after peace is signed, the author extracts from a paper by M. FALLON (published by the Minister for the Belgian Colonies) some advice which may serve as a guide to intending colonists of West Africa.

Two questions interest them specially : —

(1) What capital is required for starting a paying farm ?

(2) What profit may be expected from rational cultivation ?

I. INITIAL CAPITAL REQUIRED FOR EQUIPPING A FARM IN WEST AFRICA.

The capital required for the equipment of a farm obviously varies according to the conditions of the locality in which it is situated. The following figures are average ones and are only given as an example : —

(A) *Market garden farm of 20 hectares on the outskirts of Elizabethville.*

	Fr.
25 labourers for 6 months at 18 fr. per month	2 700
Tools : shovels, spades, wheelbarrows, rakes, hoes, watering cans	500
2000 kg of potatoes at 0. 80 fr. ker kg.	1 600
Purchase of garden seeds, maize, groundnuts, sorghum and beans	200
200 fruit trees at 3. 50 fr. each	700
50 chickens at 10 fr. each	500
20 rabbits at 6 fr. each	120
25 goats, at 25 fr. each	625
Poultry food : 6 sacks of sorghum at 30 fr. each	180
Colonists' food for 6 months	1 200
Unforeseen expenses, such as loss of animals, purchase of various things	500
Total Fr.	8 825

The cost of housing and the rent of the land are ecluded.

(B) *Large farms worked with draught animals.* Examples of farms of 100-200-500. ha worked in the Katanga district free from tsetse fly.

	100 ha.	200 ha.	500 ha.
Agricultural stores	4 000 fr.	7 000 fr.	14 000 fr.
Tools	1 000 »	1 200 »	2 000 »
Carts	1 000 »	1 000 »	2 000 «
Miscellaneous	3 000 »	4 000 »	7 000 »
Labourers for 1 year	50 = 9 600 »	100 = 19 200 »	200 = 38 400 »
Oxen at 300 fr. each	50 = 15 000 »	70 = 21 000 »	150 = 45 000 »
Harness	500 »	700 »	1 500 »
Food of colonist for 1 year	2 400 »	2 400 »	2 400 »
Temporary housing, stables.	3 000 »	4 000 »	5 000 »
Unforeseen expenses	4 000 »	5 000 »	5 000 »
Total Expenses	43 500 fr.	65 500 fr.	122 300 fr.
Expenses per ha. for the 1st. year	435 fr.	328 fr.	245 fr.

Mechanical culture. — Working a farm with machinery is not really economical unless it is extensive. A steam tractor is not advisable on farms of less than 400 ha., though a small tractor might be useful on a farm of 100 ha.

The profit in cultivating at Katanga lies in the high prices fetched on the market by all agricultural produce.

Sale price and rent of agricultural land.

1st *Class.* — Land situated on the outer boundaries of towns, inhabited centres or on strips of 150 m. along the railways or navigable rivers : — sale price, at least 5 fr. per ha. ; rent, 5 % of the sale price.

2nd *Class.* — Land situated at least 5 km. outside the previously mentioned limits : — sale price, at least 3 fr per ha. ; rent 5 % of the sale price.

3rd *Class.* — Land situated at least 15 km. outside the previously mentioned limits : — sale price at least 1 fr. per ha. ; rent 5 % of the sale price.

Cost of different kinds of houses. — The cost is obviously very variable according to the size of the building and also according to the materials used in its construction. If one is contented with local materials and rammed earth to commence with, the cost for a single roomed house would be 500 to 1000 fr. and for a double roomed house 1200 to 1300 fr. A brick house, 2 rooms, costs 4000 to 6000 fr. and with 3 rooms 10 000 to 15 000 fr.

An iron house with a floor area of 31 square m. and 2 rooms costs 3000 to 5000 fr. With 3 rooms and a floor area of 115 square m., the cost would be 9000 to 12 000 fr.

Wages of native labour. — The supply generally exceeds the demand and the tendency of wages to rise is due to dearer living. Agricultural labourers get 10 to 20 fr. a month, more usually 12 to 15 fr. Carriers receive 0.50 fr. a day and take loads of 30 and 35 kg. without difficulty.

In bush country, clearing takes, on the average, 100 days work and costs 40-70 fr. per ha. In forest clearing, felling, stumping, chopping and burning wood may be taken at an average of 300 days work per ha. and the cost at 140 to 180 fr. To that sum must be added 30 to 50 fr. for getting the land in order, filling up depressions, levelling and extracting roots.

II. — Profits to be made by colonial cultivation. These profits are obviously very variable according to the kind of crop and the year. As an example the results obtained are here given : — (1) for a rubber plantation ; (2) for a coffee plantation ; (3) for maize.

(1) Hevea plantation at Yangambi (Stanleyville) (high forest country).

(A) Creation of the plantation.

	Fr. per ha
Clearing, getting the land in order: 900 days at 0.65 fr. (1)	585
Levelling, holing: 330 days at 0.65 fr.	195
Nurseries: 20 days at 0.65 fr.	13
Transplanting: 40 days at 0.65 fr.	26
Total	**819**

(B) Maintenance of the plantation.

Weeding: 45 days at 0.65 fr.	29.25
Taking away broken and diseased trees, replacing them: 12 days at 0.65 fr.	7.80
Treatment of diseased trees: 18 days at 0.65 fr.	11.70
Green manuring: 26 days at 0.65 fr.	16.90
Upkeep of roads: 5 days at 0.65 fr.	3.25
Total	**68.80**

Yield : — 200 to 300 kg. of dry rubber per ha. worth 5 to 6 fr. per kg.

(1) The high cost of clearing is due to the fact that, for Hevea, it is necessary to stump completely the land to be planted. (*Author's note*).

(2) Coffee plantation at Lula (Stanleyville).

(A) Creation of the plantation.

	Fr.
Creation and upkeep of nurseries: 404 days at 0,52 fr. (1).	210.08
Clearing and getting the land in order: 5090 days at 0,52 fr.	2 646.80
Filling in, levelling, digging, extracting roots: 1 478 days at 0,52 fr. .	768.56
Staking, making and filling in holes: 1 220 days at 0,52 fr.	637.40
Planting and shading: 235 days at 0,52 fr..	122.20
Green manuring and draining: 355 days at 0,52 fr.	184.60
Total Expenses . . .	**4 566.64**

Expenses per ha.: — 304.45fr. for an average yield of 1 000 kg worth 1 350 fr.

(B) Maintenance of the plantation (Account for a plantation of 106 ha.).

	Fr.
Weeding, cutting green manure, upkeep of roads and drainage: 5 667 days at 0,65 fr.	2 946.84
Pruning coffee bushes, shade trees and terraces of *Leucaena glauca*: 1 007 days at 0,52 fr.	523.64
Diseases and pests of coffee bushes: 326 days at 0,52 fr.	169.52
Total Expenses . . .	**3 640.00**

Expenses per ha.: 35 fr.

(C) Picking and preparation of coffee berries.

	Fr.
Picking 315 251 kg. of berries.	2 613.91
Sorting	1 806.79
Pulping, fermenting, washing, drying, husking and manipulating the coffee, water supply for machinery, wood cutting	2 343.50
Total Expenses . . .	**6 764.20**

The yield for 1916 being 60 000 kg. of prepared coffee, the cost of picking and preparation is about 0,11 fr. per kg. of coffee.

(3) Maize cultivation at Katanga.

(A) Preliminary work effected by steam engines.

The use of steam ploughs cost daily: —

	Fr.
2 mechanics.	50
Oil for cylinders, 15 litres Oil for joints, 17 litres	56
8 labourers	12
Amortisation	63.33
Total Expenses . . .	**181.33**

(1) This includes all expenses except the salaries of the European staff. (*Author's note*).

In virgin soil 1.5 ha per day is ploughed. In land previously cultivated, free from ant hills and marsh as much as 4 ha. a day may be ploughed. 4 ha. can be harrowed per day.

Ploughing and harrowing 1 ha. in virgin soil costs 165.40 fr.; ploughing and harrowing 1 ha. in cultivated land costs 80.75 fr.

(B) Preliminary work effected by draught animals.

6 oxen at 250 fr. After 3 months the animals are sold at half price, say a loss of 750 fr.

	Fr.
1 driver at 100 fr. a month. 2 labourers at 30 fr. a month.	160

Area ploughed in a week : — 2 ha.
Area harrowed in a week : — 3 ha.

In 1 month 9 ha; which makes $\frac{750}{3} + 160 = 410$ fr. Say 29.28 fr. per ha. Total : — 45.50 fr. + 29.28 fr. = 74.78 fr.

This figure should be increased by the amortisation of plant estimated at 800 fr.; period 4 years ; annual working season 6 months ; this makes 12.50 fr. per month and 0 fr. 54 per ha.

One ha. ploughed and harrowed with oxen costs 75.32 fr. We have just seen that 1 ha. worked by mechanical means costs 165.40 fr. or 80 75 fr. according to the state of the soil.

Supplementary expenses for the cultivation of maize.

	Fr. per ha
Seed	7.50
Sowing, weeding, earthing up, harvesting	66.00
Sacks for 1.500 kg. at 1.60 fr. each	24.00
Amortisation	2.00
Renting value of land cleared and ploughed by the Agricultural Department at 300 fr. per ha. at 5 %	15.00
(If the colonist does the clearing at his own expense this amount is certainly not exaggerated).	
Cost of carring the crop for a farmer near a town at 10 fr. a ton (crop of 1 500 kg. per ha.)	15.00
Total Expenses	**129.50**

Recapitulation. — One ha. of maize, ploughed and harrowed with mechanical means, will cost 210.25 fr. without taking into account the transport of the material (in virgin soil 294.90 fr.); 1 ha. of maize ploughed and harrowed with oxen will cost 204.82 fr..

Maize sells on the spot, at Katanga, at 250 to 300 fr. per ton.

It can be seen from these few examples what profit can be made from a colonial farm cultivated rationally.

114 – **Correlations in the Cost of Milk Production, in the United States.** — Hopkins, J. A., junior, in *Dairy Science*, Vol. II, No. 2, pp. 63-98, and No. 3, pp. 208-255. Baltimore, March and May, 1919.

An attempt to discover some of the correlations existing among the different economic factors in the dairy industry and especially to bring to light the effects of these factors on the production and cost of production of milk. It is based on statistics established and used for the

investigation of the relations between the size of a dairy and economy in milk production (1).

All data are for the year 1916; the interest on capital is calculated at 5 %; depreciation and insurance are estimated at 20 % for cows and at 12 % for bulls; manure is assigned an arbitrary value of 1 dollar per ton.

CORRELATIONS BETWEEN LABOUR AND OTHER FACTORS IN MILK PRODUCTION. — The 87 dairies of Delaware and Pennsylvania concerned in the statistics were divided, for the purpose of the investigation, into 16 classes, not only according to the number of cows per dairy but also according to the number of hours of labour employed in them during the year and according to the importance of the product which they sold, namely :—

(*A*) Dairies producing market milk : — (*a*) employing annually less than 140 hours of labour per cow : — (1) dairies with less than 20 cows; (2) with 20 to 39 cows; (3) with 40 cows or more; (*b*) employing annually from 140 to 200 hours of labour per cow : — (4) with less than 20 cows (5) with 20 to 39 cows; (6) with 40 cows or more; (*c*) employing annually more than 200 hours of labour per cow; (7) with less than 20 cows; (8) with 20 to 39 cows; (9) with 40 cows or more.

(*B*) Dairies producing butter (all except 2 with less than 20 cows) : — (10) employing annually less than 140 hours of labour per cow; (11) from 140 to 200 hours; (12) more than 200 hours.

(*C*) Dairies producing milk of superior quality and milk for children (all with more than 20 cows) :— (13) employing annually less than 140 hours of labour per cow; (14) from 140 to 200 hours; (15) more than 200 hours.

(*D*) Dairies producing "certified milk" of guaranteed purity; all with 80 cows or more and employing annually more than 200 hours of labour per cow.

For this investigation and for these which followed, statistical abstracts for each class are given in tabular statements, are represented in diagrams and are discussed; a summary is given of the conclusions established

It cannot be said that the labour used in the dairies where less than 140 hours of labour per cow was employed annually was positively insufficient, for in several cases, with good organisation, satisfactory results were obtained even with much less labour. It should not be forgotten that the following conclusions only apply to the averages of the dairies included in this study.

(1) Up to an average of 168 hours of labour per year per cow, the revenue of the dairy increased with an increased number of hours of labour; in other words, up to that limit, each unit of labour applied gave an increase in production higher than that given by the preceeding unit.

(2) After the above-mentioned average, the advantage decreased.

(3) Dairies in which from 140 to 200 hours of labour per year per cow was employed have a larger capital per cow in buildings and equipment compared with dairies in which less than 140 hours or more than 200 hours of labour is employed.

(1) See *R.*, April, 1919, No. 513. (*Ed.*)

(4) Dairies employing the most labour pay a higher price for it.

(5) On an average, the cost of milk production per quart is lower in dairies employing annually from 140 to 200 hours of labour per cow than in those employing either more or less.

(6) Dairies employing larger amounts of labour per cow had more vigorous calves dropped and a greater production of manure.

(7) Where more labour was employed, the other expenses increased in proportion, but not so rapidly, as that of labour.

CORRELATIONS BETWEEN THE AMOUNT OF CONCENTRATES GIVEN AND OTHER FACTORS. — The 87 dairies in which these investigations were made were divided, for the purposes of this inquiry, into 3 groups according as each cow was given annually :— (*A*) less than 2000 lbs of concentrates ; (*B*) from 2000 to 2999 lb ; (*C*) 3000 lbs or more.

Each of these groups was subdivided into 3 according as the dairy contained :— Fewer than 20 cows ; 20 to 39 cows ; 40 or more.

The results are summarised as follows :—

The value of the cows rose with the increase in the consumption of concentrates. This was partly due to the better condition of the cows resulting from more intensive feeding and partly to a difference in their productive capacity.

(2) With the increase in the quantity of grain per cow there was also a slight increase in the quantity of silage consumed.

(3) The quantity of forage consumed decreased as the consumption of concentrates increased.

In the smaller dairies this was partly due to more intelligent use of roughage in those using a larger quantity of concentrates.

(4) Slightly more labour was employed in dairies in which large quantities of grain were given.

(5) The production per cow increased as more concentrates were consumed, but :

(6) There is an inverse correlation between the quantity of concentrates fed and the production of milk per unit of weight of grain. Large dairies can produce more milk per unit of weight of grain than the small dairies when only a small quantity of grain is used, but, when a larger quantity is used, this advantage is lost.

(7) The cost of milk per unit of volume tends to increase slightly with an increase in the consumption of concentrates.

CORRELATIONS BETWEEN THE PROPORTION OF CONCENTRATES PURCHASED AND THE COST OF MILK PRODUCTION. — The dairies for which statistics were collected were divided into 3 groups according as the percentage of concentrates purchased relatively to the total concentrates fed was :— less than 50 ; from 50 to 79 ; from 80 to 100 ; each of these groups was subdivided into 3 classes according as the dairy contained :— fewer than 20 cows ; 20 to 39 cows ; 40 cows or more.

The results were as follows :—

(1) It was noticed that the greater the incentive to saving and economy in expenditure, the smaller the proportion of concentrates purchased.

Thus the tenant farmers, who may be assumed to have a greater incentive to save, purchased a smaller proportion of concentrates than the owners. Similarly, the owners of small dairies, whose economic conditions may be assumed to be inferior to those of the owners of large dairies, mostly belong to the groups buying less than 80 % of the grain consumed. The middle group of dairies are found for the most part in the group buying the most grain.

(2) In the classes purchasing from 50 to 79 % of the grain used, a much larger amount of food, both forage and grain, was fed than in the classes which bought less than 50 %. This may be attributed, as noted above, to a greater liberality in expenditure on the part of the farmers. But the dairies which purchased the largest proportion of grain, use less food than any of the other classes. This may be attributed to the better quality of the food used and to the more efficient use made of it.

(3) The middle group of dairies employ the smallest amount of labour.

(4) Production, cost, and profit or loss per unit of volume of milk are influenced by the 3 factors noted above. But the reciprocal effects among these factors and others are such as to make it impossible to state that production, cost, and profit or loss per unit of volume of milk are influenced by the proportion of food purchased relatively to that grown on the farm.

CORRELATIONS BETWEEN THE AMOUNT OF FORAGE FED AND THE OTHER FACTORS IN MILK PRODUCTION. — The dairies included in the statistics were divided for the purposes of this enquiry into 3 groups according as each cow received annually less than :— 1.5 tons of forage; from 1.5 to 1.9 tons ; 2 tons or more ; each of these groups was subdivided into 3 classes, as in the previous cases, according to the number of cows per dairy.

Many small dairies use large amounts per cow of cheap roughage of low nutritive value while the larger dairies use forage of better quality. This makes a comparison between amounts of forage alone erroneous, but the following conclusions may be taken as sufficiently safe :—

(1) In dairies which make an efficient use of forage there is a tendency for the value of the cows to be higher.

(2) Generally more grain is used in dairies where a greater amount of forage is used.

(3) An increase in the amount of forage is generally accompanied by an increase in the amount of labour.

(4) The yield per cow tends to increase, but not proportionally, with an increase in the amount of forage fed, and at the same time, up to a certain point, the cost of production per unit of volume of milk probably decreases and the profit per unit of volume increases if the increase in the amount of forage is not accompanied by a corresponding or greater increase in one of the other factors of expenditure.

CORRELATIONS BETWEEN SILAGE AND OTHER FACTORS. — For this enquiry the dairies were divided into 3 groups according : — as they consumed no silage ; as they consumed less than 6 tons per cow annually ; as they

consumed 6 tons or more ; each of these groups was subdivided into 3 classes as in previous cases. The following facts were noted :—

(1) Silage is not generally used in small dairies or on tenant. farms.

(2) A greater amount of silage is used in dairies containing cows of high value.

(3) The use of silage instead of pasturage increases the cost of milk production.

(4) The total amount of forage at first is reduced, then increased as at first little, then much, silage is fed.

(5) Increase in the amount of silage fed is accompanied by an increase in the amount of grain consumed and in the amount of labour

(6) Production is increased by the use of silage, but the cost of production per unit of volume of milk is also increased, partly or wholly, by the effect of using more grain and labour and less pasturage.

Correlations between the value of the cows and other factors. — The dairies were divided into 3 groups according as the average value per cow was under $75, $75 to $90, or over $90 ; each of these groups was subdivided into 3 classes according to the number of cows, as in previous cases. It was noted that :—

(1) The value attributed to the cows by their owners and at which they found buyers, supplies a sufficiently accurate index of their productive capacity if a large number of dairies are considered. In individual cases an accurate appraisal was not always obtained, but variations from the normal tend generally to neutralise each other.

(2) Investment in buildings and equipment showed no correlation to the value of the cows.

(3) The more valuable cows receive more silage and are pastured less than less valuable cows.

(4) These is a general tendency to feed less forage and a well defined tendency to feed more grain to the more valuable cows, which shows the capacity of the more valuable cows to consume greater quantities of food, especially grain.

(5) More labour is devoted to the more valuable cows.

(6) The cost of production per unit of volume of milk showed conflicting variations, which proves that other factors besides the natural productivity of the cow influence the cost.

(7) Except in the case of dairies producing milk of superior quality, the owners of the more valuable cows accept lower prices for their products than those obtained by owners of cows of medium value.

(8) The less satisfactory marketing methods of owners of more valuable cows were more than compensated by the greater productivity of those cows, with the result that the profit per unit of volume of milk was higher.

Correlations between tenantry and other factors. — The principal difference between dairies worked by their owners and those worked by tenants lies in the tendency to greater saving and in less liberality in expenditure on the part of tenants.

The owner has also a tendency to spend less on dairies which he lets out, so that the cows often suffer from the excessive thrift of the owner and of the tenant.

Production, its cost, and profit per unit of volume of milk are generally in favour of dairies operated by their owner but the differences are slight and inindividual cases may be nil.

PRODUCTION. — For this enquiry the dairies were divided into 3 groups according as the annual production per cow was less than 2 200 quarts, from 2 200 to 2 800 quarts, or more than 2 800 quarts ; each of these groups was subdivided into 3 classes according to the number of cows per dairy in the usual manner. It was noted as follows :—

(1) The general increase in production from one group to another was accompanied and caused by a simultaneous and proportional increase in the use of each of the principal factors of production.

(2) While an increase in the use of any one isolated factor may give rise to a very slight increase in production, if all the factors increase simultaneously and proportionally the production may respond proportionally.

(3) An increase in production does not necessarily imply a greater cost for each new increment, and it may even be accompanied by a decrease in the cost.

COST OF PRODUCTION. — For this enquiry the dairies were divided into 3 groups according as the net cost of milk was less than $0.050 per quart, from $0.050 to $0.064 per quart, or $0.065 or more per quart; each of these groups was subdivided into 3 classes according to the number of cows per dairy in the usual manner. The results are summarised as follows : —

The " cost of production per unit of volume ", like " production ", is not a simple factor like the factors " amount of labour ", " silage ", " grain " etc., but is a complex of all the factors in the cost of production. If a product of uniform grade and quality is considered, the cost of production per unit of volume is the most satisfactory measure of efficiency of production. Since the best system of management and feeding differs according to various conditions, it is to be expected that only those factors which vary slightly in different systems of management of cows should show well defined correlations with the cost of production per quart of milk and that the other factors should be more or less distorted by contrary factors. It may, however, be said that : —

(1) The cost of production per quart of milk is lower in dairies composed of valuable and highly productive cows than is those composed of cheap and poorly productive cows.

(2) The replacing of pasturage by silage is accompanied by an increase in the cost of production.

(3) The dairies which produce the cheapest milk are enabled, by good management, to use less labour than dairies which produce milk at a higher cost.

(4) Factors which lessen the cost of production by efficiency of system and management also give a higher production.

(5) Dairies which suffer the heaviest losses on their products succeed in partially reducing this loss by finding buyers who pay the highest prices for the products in question. But this increase in price is insufficient to eliminate the increase in the cost of production and those which produce milk at the highest cost suffer the heaviest losses per quart.

Conclusions. — (1) Units of labour are most productive about the upper limit of the medium class for the amount of labour employed.

(2) There is an inverse correlation between the quantity of grain consumed per cow and the production per unit of grain.

(3) The proportion of food bought does not necessarily influence the cost of production.

(4) When forage is used efficiently, production may be increased and its cost decreased by using large amounts of forage of good quality.

(5) The use of large amounts of silage increases production, but is accompanied by an increased cost of production per unit of volume of milk, caused more or less by the simultaneous increase in the use of grain and labour and by the substitution of silage for pasturage.

(6) The price at which cows are sold provides a sufficiently satisfactory measure of their productive capacity.

(7) Tenantry has not much effect on the dairy business, except the tendency to give the cows too little care and to spend too little to bring them to the point of maximum efficiency.

(8) An increase in production does not necessarily imply a greater cost per unit of product, and an increase obtained by a proportional increase in the use of all factors may also have the results of reducing the cost.

(9) Low cost of production which accompanies increased profit depends chiefly on the ability of the dairyman to use the different factors of production in the most favourable proportions in the particular circumstances in which he is situated.

115 – **The Cost of Milk Production Computed on the Year Basis.** — Pearson, F. A., in *Illinois Agricultural Experiment Station Bulletin* 216, pp. 343-364. Urbana, Ill., 1919.

These studies were undertaken to derive workable formulae that would express the cost of producing fluid milk (for the Chicago market) in terms of amounts of feed and labour used, and not of the monetary value of the expenses incurred.

A study of the herd cost is based upon the records during the fiscal years 1914-15 and 1915-16 of 36 farms on which there were 873 milch cows, 225 calves (and heifers not in milk) and 35 bulls, and where 6511 lb. of milk and 235 lb. of butter fat were sold per cow during the period. Production in the 6 winter months was 56 % of the yearly total. The gross cost of producing 100 lbs. of milk was found to average $2.25, the percentage of the several items being: Feed other than pasture 60.7; pasture 5.3; man labour 17; horse labour 3.4; interest on herd 4.9; building charges 3.6; equipment 1.3, and miscellaneous 3.8. A managerial charge

was not included. The cost other than for feed (excluding pasture) and man labour totalled 50.16 cents, which almost exactly balanced the 49.69 cents credit from appreciation of stock, manure, hides, beef and other miscellaneous returns. The production cost on these farms can thus be expressed in terms of feed and labour. The amounts per 100 lb. of milk were approximately 44 lb. of grain; 188 lbs. of silage and other succulent feed; 50 lb. of hay; 39 lb. of other roughage and bedding; 2.42 hours of man labour. This is the formula for " year cost ".

To correct for seasonal variations in cost of production it is suggested that the price of any month be that percentage of the year cost which represents the average variation of that month from the average year price during the period 1907-1916. A table showing these monthly percentages is given. It is noted that only 61.8 % of the grain fed was purchased, whereas in farms providing milk for New York City the purchased grain was about 98 % of the total (A. L. THOMPSON, Cost of Producing Milk on 184 Farms in Delaware County, New York, in the *New York Cornell Station Bulletin* 364, pp. 109-179. 1915).

In 16 of the above farms, embracing 428 cows, the records permitted the separation of the cost of rearing young stock from the herd cost, the difference being the " cow cost ". The net cost of producing 100 lb. of milk on this basis was $ 1.70, which is 215.6 % of the cost of feed (excluding pasture) and man labour. The amounts of feed and labour were approximately : Grain 35 lb.; silage 140 lb.; hay 36 lb.; other roughage 29 lb., and man labour 2.36 hours. To find the year cost on this basis it is necessary to increase the total of these items by 25.6 %. Corrections for seasonal variation may be made as before.

A short discussion of some data from 680 dairy farms in Kane and Mc Henry Counties in Illinois is given, mainly to show that the " farm cost ", obtained by deducting from the total farm expenses the receipts derived from all sources except the dairy, is a misleading measure of milk production costs.

AGRICULTURAL INDUSTRIES

INDUSTRIES DEPENDING ON VEGETAL PRODUCTS

116 - **Information Regarding the Choice of Apples intended for Making Cider.** — See No. 59 of this *Review*.

117 - **Oil Content of Linseed grown in the United Kingdom in Relation to Origin.** — See No. 48 of this *Review*.

118 - **The Copra Industry of the West Indies.** — MEYERS, L. M. B., in *Weekly Bulletin, Department of Trade and Commerce, Canada, Commercial Intelligence Branch*, Vol. XXI No. 814, pp. 478-481. Ottawa, Sept. 8, 1919.

The copra industry in the West Indies might be said to be in its initial stage, except perhaps in Jamaica, Trinidad, and British Guiana, but even in those colonies it is capable of far greater development than it has hitherto attained.

During the war there was a great demand for copra, owing to the shortage and increased demand for animal and vegetable fats, which gave the industry a new impetus. Greater attention has therefore been given to it in most of the coconut-growing islands and the colony of British Guiana, and it is generally considered that the future of the industry bids fair to be promising.

In his annual report on the trade of Jamaica for 1917-18, the Acting Colonial Secretary stated that the copra industry was extended during the year and that drying plants are being erected in ever increasing numbers in coconut districts. Allowing for nuts converted into copra, the exports of coconuts amounted to 30 000 000 nuts, and but for the hurricane, a remarkable progress of the industry would have been established. Large numbers of young trees, he states, were then coming into bearing, and with average good fortune, the exports of the industry should show a progressive increase for the next ten years.

Special mention of the industry was also made by the Colonial Secretary of Trinidad and Tobago in his annual report on the trade of those colonies for 1917. He states that the cocoanut industry has now quite recovered from the droughts which affected it in former years, and though the number of nuts exported in 1917 was 1 253 925 less than in 1916, this was more than compensated for by an increase in the exports of copra, which rose from 3 339 848 lb. in 1916 to 7 201 448 lb. in 1917 which, he states, is equal to about 18 000 000 nuts.

In the annual report on the trade of British Guiana for 1918, the Comptroller of Customs also made special mention of the coconut industry as one of the sources of increased revenue of the colony, and stated that, owing to the increased demand for coconut oil and copra, there was a large increase in the output, the increase in the latter being 109 798 lb. Two-thirds of the total yield of copra for 1918 was exported to the United States, while one-third went to the United Kingdom. The total output of coconut oil in British Guiana in 1916 was 17 948 gallons and the value $16 523, while in 1917 the total output was 26 674 gallons and the value $28 652.

It is estimated that Trinidad produced annually about 140 000 gallons of oil for the consumption of the local population. The export is small. The amount of oil produced depends in great measure on the relative price of copra. When the export price of copra offers more profit than its manufacture into oil, the owners naturally prefer to sell copra.

In addition to the export of copra in recent years, there is a very large export of coconuts from the various colonies which gives a correspondingly large margin for the further production of copra, should there be an increase in the demand and in price.

The following comparisons showing the rise in price of copra in 1916-18 may be of interest. In 1916 the total output of copra in British Guiana was 237 104 lb. and the value $10 012, while in 1917 the total output was 168 764 lb. and the value $12 164. The total yield for the year 1918 was 278 532 lb. and this realized the sum of $20 801. These figures show that the price of copra almost doubled in 1918 as compared with 1916.

With respect to the relative oil content of copra, while there no information to hand in regard to the various grades, yet it is of interest to know that in a recent report by Professor HARRISON, the Director of the Department of Science and Agriculture of British Guiana, who is also the Government analyst, it was stated that the general average content of oil was 2-5 gallons to every 100 ripe nuts, which can be taken as a fair and correct general average for commercial purposes. It is generally considered that coconuts give their best yield of copra during the dry season of the year, which differs in each island almost.

Copra exported from the British West Indies during the years 1914—1917.

119 – **Crêping African Rubber.** — VON PELT, G., in *Institut Colonial de Marseille, Bulletin des Caoutchoucs*, No. 2, pp. 53-78. Paris-Marseilles, 1919.

The Colonial Institute of Marseilles having commissioned the author (Head of the rubber branch at that Institute) to study the conditions under which African rubbers could be improved, these rubbers being out of demand compared with plantation rubber, he has made the present preliminary study before leaving for West Africa to make a complete study of the matter on the spot. The reasons given by manufacturers to explain their preference for plantation rubber, a preference which during the last few months has been pushed to the point of refusing to buy African rubber, are: — (1) The necessity of crêping African rubbers; (2) the loss which that operation causes by washing; (3) the tendency of these rubbers to become sticky.

The author compares the manipulation of plantation rubber with that applied to African rubbers with the object of noting in what respects the preparation of the collected rubbers should be modified so as to give them, as far as possible, the qualities of plantation rubber.

He examines successively: — (1) plantation rubber: tapping, collection, straining, coagulation, preparation, drying, smoking, packing — (2) collected rubbers, not undergoing any of these treatments and consequently being of much inferior quality at the time of purchase. Crêping would only introduce some of the operations carried out on plantations into the preparation of collected rubbers. The question, in short, resolves itself into considering whether, since manufacturers state that in present circumstances it is impossible for them to do the work, the exporters ought not to think of doing it themselves. In this case the crêping of African rubber should be done before it is placed on the market. The following operation would have to be carried out :—

(1) *Cutting up.* — by means of a toothless circular saw revolving

at high speed under a jet of water, cutting up the blocks or masses of rubber into small pieces.

(2) *Soaking and softening.* — immersion of the cut up rubber :— (a) in cold water ; (b) in warm water for a length of time varying according to the kind of rubber under treatment.

(3) *Crêping, washing.* — the pieces of rubber are crushed under a jet of water between two special cylinders of a rolling mill; the impurities contained are thus mechanically carried off ; the operation is continued until perfect purity is obtained and the crêpe so formed has reached a suitable thickness determined by greater or less space between the cylinders which are adjustable.

(4) *Drying.* — the crêpe obtained by crêping is hung up in a specially conditioned place ; different methods for drying can be used, causing more or less rapid elimination of the moisture in the rubber ; a preliminary drying in the air before the rubber is placed in the drying chamber will reduce the moisture in it to a great extent.

Rubber resulting from this series of operations appears to be identical with brown plantation crêpe. The practice of crêping can be regarded in two different ways :—

(1) The only object is to place on the market an African rubber in a pure form.

(2) In addition, the creation of "botanical standards" in African rubbers is aimed at, e. g. Landolphia type, Funtumia type, etc., each of these types being clearly characterised by its physical and chemical properties which indicate them more particularly as raw material suitable for a given manufacture.

The author examines the possibility of crêping from a commercial standpoint, the conditions of installation of a creping factory (in Africa or better still in Europe), description of the working of the factory, laboratory attached to the factory for scientific research.

In the 2nd part of his paper, the author indicates shortly what conclusions, he has arrived at after a preliminary investigation carried out at the laboratory of the Colonial Institute on rubbers which had reached Marseilles ; but he could not determine a certain number of points except during his mission in West Africa.

The 3rd part of the report is devoted to the enquiry which he made in England before he embarked, from makers of rubber machinery and from large manufacturers who have specialised in the purifying of crude rubbers in that country.

120 – **"Cay-Doc" Gum from Tonkin (*Garcinia tonkinensis*).** — HEIM, F., in *Bulletin de l'Office Colonial*, Year XII, No. 138-139, p. 413-424. Paris-Melun, June-July, 1919.

A previous paper (1) was devoted to the oil of "Cay-Doc," or "Cay-Gioc" (*Garcinia tonkinensis* Vesque), belonging to the Guttiferae of Tonkin, used by the Annamites for making soap and from which French indu-

(1) See *R.*, Sept. 1917, No. 854 (*Ed.*

stry might derive much profit. The "Cay-Doc" not only provides, in its seeds, a source of oil but it also yields a gum capable of industrial use.

At the request of M. CAPUS, Delegate for Indo-China at the Colonial Office, the Governor General of Indo-China sent a sample of the gum produced by *Garvinia tonkinensis* for examination by the "Service des Productions coloniales,, of that Department. The Annamites consider that it conduces to fruiting if notched incisions are made in the bark of the tree, even on the lower part. From these notches the tree exudes fairly large amounts of gum which is seldom collected for want of a definite use.

The "Cay Doc" abounds in Tonkin in the Provinces of Phu-Tho, Tahi-Ngunyen, Tuyen-Quang, Yen-Bay, Hua-Binh, and these forests can supply large quantities of the gum at a low price. The gum has the appearance of a blackish mass, fairly hard, becoming soft between the fingers to which it soon sticks. The surface is shining. Inside the specimen, agglomerations of a sticky substance, translucid and citron yellow in colour, are found. The odour of the gum, scarcely noticeable in a block which has been exposed to the air, is stronger on a fresh section, and recalls that of oil of sweet almonds. At 60° C. the gum melts partially giving out a thick, dark brown reddish liquid in which solid black matter is immersed. On cooling the liquid portion congeals in a vitreous glaze, shining and brittle. The author gives a detailed account of the physical and chemical properties of the gum of *G. tonkinensis*.

The gum, as received by the author, contained much vegetable impurities, with a blackish brown resin which is easily separated by taking advantage of its high degree of solubility in benzine or in acetone.

This resin exists in the crude gum in the proportion of 74.2 %; the true gum forms 25.8 %.

Hydrolytic examination of the carbohydrates shows that the galactanes are almost the only ones which enter into the composition of the true gum. These galactanes are but slightly condensed and are broken down by weak hydrolysis. The pentosans are represented in this gum by arabane, but in a slight percentage; a little preformed free glucose is found in it.

The gum of "Cay-Doc" has been considered of much interest to manufacturers of products for dressing and printing textile fabrics; it gives, not a solution, but rather a kind of mucilage, prepared by heating under pressure, with or without the addition of hydrogen peroxide. Trials are being made in finishing works. Trials of its use in the paper making and cardboard industry will be made as soon as a large quantity ordered from Indo-China arrives.

121 – **Drying Fruit, Experiments in Indo-China.** — MIÉVILLE, R., in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 8, pp. 233-238, Saïgon, Aug., 1919.

Drying is the most economical method of preserving fruit, because it requires neither receptacles nor special liquids.

The author describes the experiments in drying fruit which he carried out in Indo-China; the drying was done by the sun alone, by combined action of the heat of the sun and artificial heat, and by the action of artificial heat alone.

He thinks that it is possible to increase the orchards of fruit trees without any fear of over production of fresh fruit, for dried fruit would easily find a market. The benefits, from domestic economy and commercial standpoints, which can be derived from the dried fruit industry in temperate countries and tropical colonies are undeniable. The author has the firm belief that in the near future Indo-China will take a conspicuous place in this industry.

122 – **Antiseptic Action of Spices in Preserved Foods.** — LAHACHE, JEAN, in *L'Industrie française de la Conserve*, Year V, No. 29, pp. 211-214. Paris, Aug. 1919.

The author gives an account of investigations on the antiseptic action of spices in preserved foods. All this subject is, so to speak, in its infancy, and will be continued. But already attention should be drawn to the preliminary results obtained, which establish absolutely the antiseptic action of certain spices. The spices most generally used are black pepper, Cayenne pepper, ginger, mustard, cinnamon and cloves. The first three, in the experiments, only prevented fermentation and putrefaction for a very short time. But mustard, cinnamon and cloves (whose antiseptic principles are their essential oils) are much more effective. They are powerful antiseptics, even in the small quantities, in which they are used in food industries. Anyhow, these spices have an antiseptic action decidedly greater than that of the usual chemical antiseptics of which, moreover, the use is expressly prohibited by French law, while that of spices is legally permissible and is in no way contrary to hygiene.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS

123 – **New Constant for the Investigation of Partial Skimming of Milk.** — LEDENT. RENÉ, in *Annales des Falsifications et des Fraudes*, Year XII, No. 129-130, pp. 219-225. Paris, July-Aug., 1919.

Communication to the "Society of French Chemical Experts".

As the fat content of milk varies between wide limits (2 - 3 - 6 %), adulteration by partial skimming is sometimes difficult to prove.

In 1914, M. VANDAM (Director of the Central Laboratory for the Prevention of Fraud, at Brussels) gave the results of the research which he had made with the object of establishing a constant enabling partial skimming to be proved, by taking as basis the proportion between the casein (c) and the fat (g) (1).

According to this investigator this proportion varies :—

from 0.53 to 0.72 for milk with over 40 % of fat
from 0.56 to 0.85 for milk with from 3 to 4 % of fat
from 0.67 to 0.98 for milk with from 2 to 3 % of fat

these figures having been established after examination of 144 samples of pure milk.

Skimmed milk shows a proportion $\frac{c}{g}$ greater than unity.

The great importance of this new constant in the investigation of partial skimming of milk, has led the author to undertake trials on pure milk of known origin.

(1) See *Annales des Falsification et des Fraudes*, April, 1914. (*Ed.*)

The skimming, although it only lowers the fat content and only modifies very slightly the percentage of the other elements, seems to increase slightly CORNALBA'S figure. The author thought that it might perhaps be possible to restrict the limits established by M. VANDAM for the proportion $\frac{c}{g}$ by introducing into this latter CORNALBA'S factor.

By establishing the proportion $\frac{\text{Cornalba}}{cg}$ or $\frac{\text{Cornalba}}{\text{Vandam}}$ which he calls $\frac{C}{V}$, the author has noted that the figures obtained fluctuate between very narrow limits. He gives in tabular form the figures which he obtained in the course of his experiments, and which led him to the following conclusions :—

Milk with high fat content, lightly skimmed, shows a $\frac{C}{V}$ not denoting this skimming but nevertheless possessing a reasonable food value.

The proportion $\frac{C}{V}$ would give, on the contrary, good results for the investigation of skimming in ordinary milk with low fat content. This kind of milk puzzles the chemist who has to deduce conclusions. As for the proportion $\frac{c}{g}$ it was, in certain cases, greater than unity.

124 – **The Comparative Value of Quantitative and Qualitative Bacteriological Methods of Testing Milk ; the Methylene Blue Reduction Test.** — HASTINGS, E. G., (Bacteriological Laboratory, University of Wisconsin, Madison), in *Journal of Dairy Science*, Vol. II, No. 4, pp. 293-311. Baltimore, July 1919.

The value of bacteriological analyses in the dairy industry has been established beyond all question. In all routine examinations the disease-producing organisms may be omitted from consideration and attention need be directed only to those saprophytic organisms which grow in the milk and change its composition. Four methods for the determination of the number of bacteria present in milk have been used to a greater or less extent : — (1) Plate culture.; (2) direct microscopic count.; (3) FROST'S method, called the "little plate" method, which is a combination of the two former; (4) The methylene blue reduction method, based on the fact that the colour imparted to milk by the addition of a small quantity of methylene blue disappears more or less quickly according as the bacterial content of the sample is low or high. This last method has the advantage of being the quickest, the easiest and the simplest of all, bnt it remained to be proved whether it h d th same accuracy.

The author has tried to solve this question by carrying out a series of tests, the results of which enable him to conclude that, both for raw and pasteurised milk, the methylene blue reduction test gives just as accurate results as any of the other testing methods.

125 – **Buttermilk Cheese.** — RUDNICK, A. W., in *Journal of Dairy Science*, Vol. II, No. 1, pp. 41-45, 1 fig. Baltimore, Jan., 1919.

Work done at the Iowa Agricultural Station, United States.

The author has ascertained that a cheese of satisfactory quality can be made from buttermilk derived from butter-making with pasteurised

cream, by running the buttermilk through one of the centrifugal machines now on the market for extracting the curd from skim milk in the manufacture of "' cottage-cheese " (1).

The machine consists of a hollow cylinder open at the top except for a rim 1/8 of the diameter of the cylinder ; the cylinder is supported by a spindle and enclosed in an iron frame. The curd lodges under the rim.

The casein content of the buttermilk depends on the acidity, temperature to which it is heated and the time during which it is held at that temperature. When pasteurised buttermilk containing 2.69 % of casein was held at 170° F. for one hour, the whey contained 0.266 % of casein When the buttermilk was held for one hour at 140° F. the whey contained 0.319 % of casein and when the buttermilk was heated to 170° F, but not held at that temperature, the whey contained 0.397 % of casein. The curd had more grain when the buttermilk was held for one hour at 140° F.

Buttermilk cheese made by the centrifugal process has not the disagreeable flavours which such cheese has when made in the ordinary way by neutralization with caustic soda and re-acidifying with hydrochloric acid.

The centrifugal process leaves only 0.15 % of casein in the whey if buttermilk from pasteurised sweet cream is used. This buttermilk, held at a temperature of 95° — 115° F for an hour after the acidity had reached 0.065 %, produced a cheese equal, in flavour and texture, to cottage-cheese.

126 – **The Chemical Investigation of Spoiled Meat.** — I. Falk, K. G., Baumann, E. J., and McGuire, G., in *The Journal of Biological Chemistry*, Vol. XXXVII, No. 4, pp. 525-546, 9 fig. Baltimore, Apr., 1919. — II. Falk, K. G., and McGuire, G., Ammonia Test for Meat Spoilage, *Ibid.*, pp. 547-550.

I. — Most of the investigation described by the authors were made with meat or meat broth inoculated with micro-organisms isolated from meat and thought to be responsible for actual cases of poisoning. The general method employed was to study the chemical changes caused by the micro-organism under investigation in the following components : Total nitrogen ; non-protein nitrogen ; ammonical nitrogen ; nitrogen in the form of creatins ; nitrogen in the form of purin. Most of the micro-organisms belonged to the colon-typhoid group ; for comparison, the authors used *Streptococcus brevis* and the spore-forming *Bacillus subtilis*.

The results given in tubular form show some marked differences as well as similarities in the action of different groups of micro-organisms, which indicates that the bacteria exert certain selective actions on defined substances or groups of substances. The increase in the ammonia content was a constant factor the significance of which is discussed in the following paper.

II. — The marked increase of ammonia content in meat decomposing

(1) " Cottage-cheese " or " Pot-cheese ", names under which fresh curd, generally mixed with milk or cream, is known in the United States. — Cf. *Standard Dictionary of the English Language*, Vol. II, p. 324. New York Funk & Wagnalls C., 1910. (*Ed.*)

at ordinary temperatures pointed to the possibility of using that factor as a chemical test in investigating meat spoilage. The determinations of ammonia were made according to the aeration method and according to FOLIN and BELL's method (1) on samples of beef undergoing decomposition at room temperature or at a low temperature.

At ordinary temperatures bacterial growth was rapid, especially at the higher temperatures, and the meat soon became unfit for use, in some cases after 24 hours. At low temperatures, there was a considerable growth of mould and little bacterial growth, but after cutting off the thin superficial layer infested by the mould, the meat was still usable after standing for 3 or 4 weeks at a temperature varying between 0° and 5° C. and for much longer at still lower temperatures.

The ammonia content of the two forms of spoiled meat was very different. The fresh meat (beef within 24 hours of slaughter and refrigeration), contained between 0.03 and 0.10 mgm. of ammoniacal nitrogen per gramme of meat. The meat decomposed at ordinary temperatures (15-25° C.) became unsuitable for food when the ammoniacal nitrogen content reached 0.3 to 0,4 mgm. per gramme of meat. At low temperatures the ammonia content was much higher before the meat became unsuitable as food ; it varied between 1 and 3 mgm. per gramme.

The authors refer to the works of HOAGLAND and his collaborators (R. HOAGLAND, C. N. MCBRYDE and W. C. POWICK, *United States Department of Agriculture, Bulletin* No. 433, 1917) who considered that the increase in amino-nitrogen was the best way of measuring the extent of autolysis in meat in cold storage, and remarked that at ordinary temperatures the growth of bacteria is relatively rapid and that the meat becomes unsuitable for food even with a low ammonia content. At low temperatures bacterial growth is slow, but autolysis proceeds in such a way that the products of decomposition such as ammonia and the compounds rich in amino-nitrogen increase greatly without the formation of those products, whose odour, appearance and flavour, render the food unsuitable for use. If the meat is kept cold first, autolysis proceeding, and is then brought to an ordinary temperature, decomposition would be much more rapid, because simpler products are formed by autolysis which would serve as nutriment for bacteria and would greatly increase their growth. This is perhaps, in addition to the physical effects of the rupture of cell walls by freezing, a reason for the more rapid decomposition of meat which has been for some time in cold storage.

---

(1) O. FOLIN and R. D. BELL, *Journal of Biological Chemistry*, Vol. XXIX, p. 329, 1917. The ammonia is extracted from a solution by means of permutit (zeolite composed of silicate of alumina), specially prepared. The ammonia is then set free by a fixed alkali and determined by Nessler's process. The method eliminates the possibility of decomposition (by the alkalis) of the protein or any other matter present, and its results indicate better the quantity of ammonia or ammonium salt present in the meat. (*Author's note*).

127 – **Tripoli Wools and Means of Improving Them.** — CASELLI, A., in *Bollettino dell'Industria laniera*, Year XXXIII, No. 8, pp. 158-161, Biella, Aug. 31, 1919.

Given its natural conditions, Tripoli is much more suited to the breeding of flocks than to agriculture, and, owing to the coarseness of its fodder flora, especially that of sheep and goats. Before the war Tripoli exported anually abont 100 000 sheep, especially to Alexandria (Egypt) and only a small number to Malta and Italy The total number of sheep in Tripoli certainly exceeds one and a half million head. On an average the flocks number 300 to 400 head.

Except the Sudanese sheep, bred in the Sonthern part of Tripoli, the rest belong to the Syrian breed, Barbary variety, with fat tails, covered with wool over the whole body, except part of the head, the legs, and the front part of the tail. If these sheep were kept with care and protected from skin diseases, they would give a very fine fleece, but the carelessness with which they are kept often makes the wool coarse. The wool which comes from the eastern part of Tripoli is more valued than that from the western part. An animal in good condition of health and feeding gives 3 to 4 kg. of wool ; in exceptional conditions it may give 6 or more.

Shearing is done in an irrational manner, with imperfect instruments (scissors), and without grading according to quality. Wool is sold in the market at 80 fr. a quintal, if it is dirty, and 240 fr. a quintal, if it is washed and of good quality. The loss of weight in washing thoroughly varies from 55 to 56 %.

The examination of 8 samples of sheep's wool, from the districts of Tarhuma and Cussabat, gave : — Length of staple 6 to 9 cm. : loss by washing in water 43 to 55 % loss of wool washed in ether 8.7 to 11.5 %. The examination of 8 samples of wool from Msellata gave : — Weight of fleece before washing 2.7 to 4.1 ; after washing in cold water 1.000 kg. to 1.80 kg. ; loss in washing 1.6 to 2.5 kg. The fleece soils easily because it is open and the strands are conical ; it is chiefly particles of earth which soil it.

Tripoli wool is generally wanting in uniformity and is formed of strands of variable thickness, not only one strand with another, but also the same strand, which is sometimes thicker at the base, sometimes at the extremity, or else shows strictures (corresponding to the dry season), which makes it easily broken in weaving. As regards length Tripoli wools can be classed among long or carding wools ; as regard fineness, althongh there is room for improvement, they are not inferior to common Tuscan wools and second-rate cross-bred wools from Buenos Aires.

The examination of 15 samples, made at the technological laboratory of the Italian Colonial Agricultural Institute at Florence, has given the following average results : — *Wool from the shoulder* : — relative length of staple 13.3 cm. ; full length : — minimum 18.3 cm ; average 20.4 cm ; maximum 22.1 cm. ; diameter minimum 32.15 cm. ; average 45.15 cm. ; maximum 63.74 cm. ; stretching in mm per 100 mm : — minimum 21.76 : average 36.17 ; maximum 45.81 ; weight in gm. supported to breaking point: — minimum 8.3 ; average 15.4 ; maximum 30.6 — *Wool from the hindquarters*:

— relative length of staple 15.6 cm. — full length: — minimum 15.6; average 19.3; maximum 21.4 — diameter: — minimum 35.09 cm.; average 45.27; maximum 63.44 cm.; — stretching in mm per 100 mm: — minimum 22.93; average 35.33; maximum 47.97 — weight in gm. supported to the breaking point: — minimum 7.7; average 15.9; maximum 27.1.

As it has been seen, elongation is very marked (about 35 %), and even excessive for good weaving wool. The fleeces are often curly, but less than those of Merinos. When Tripoli wools are dry they do not absorb or hold a great quantity of water; on an average 10 to 15 %. In terms of comparison for Tripoli wools, the following data may be used (average of 8 samples), relating respectively to wools of the 1st and 2nd shearing of the cross-bred race Vissano-Maremmana × Bergamasca, which is considered a good breed for wool: — Full length 119.7mm. and 82.6mm.; diameter 35.3μ and 32.7μ; breaking strain 8.125gm. and 9.611gm. — stretching 25.62 and 22.97 %.

For improving the Barbery breed, crossing with European breeds cannot be relied on, as is shown by experiments made in the Algerian Sahel, and in certain regions of Tunis, where the produce of crossing with the Rambouillet-Mérinos breed did not stand the indigenous method of treatment, where that with the Soissons breed degenerated rapidly, and that with the Merinos of Crau gave inferior results to those of the local breed. Crossing with Sicilian or Sardinian sheep has been advised, but they yield less, and give a coarser wool than the indigenous sheep; the proof of this in that Barbery rams are imported into Sicily and Sardinia to improve the breeds. It only remains, therefore, to have resort to selection, which must aim first at production of wool and meat, and afterwards of milk. Useful technical improvements would be: — the use of shearing machines the washing of wool after shearing; the grading in different classes of wool, which is at present sold by entire fleeces; the founding of central markets.

128 - **Indo-Chinese Silks and Silk Goods at the Lyons Fair (France).** — *Bulletin des Soies et des Soieries*, Year XLIII, no. 2210, pp. 2-3, Lyon, Oct. 4, 1919.

The "Economic Agency of Indo-China" has organised in its stalls at the Lyon Fair a very complete exhibition of Indo-Chinese silks and silkgoods. Regarding raw silk, Indo-China produces a raw-material which, in the French market, could be used on equal terms with "Canton silk" and might even be superior to it.

Under the influence of the French Administration, helped by experts, especially from Lyons, the natives gave up, by degrees, their crude processes and adopted more improved methods, which enable them to produce raw silks, exportable waste and textiles, welcomed by the market of Lyons.

The first changes, recommended by the Administration, regarding the breeding of silk-worms, plantation of mulberries, spinning, preparation of by-products, and weaving, have been adapted to local means and possibilities.

An entire series of samples and models of apparatus furnish a realistic demonstration of the continued efforts which have led Tonkin and Cambodia to take a place, which is still too modest, among the countries producing the silk required by the Lyon factories (1).

Besides native made-fabrics for local use, and new materials (of the tussore, shantung and pongée kind) for exportation, fabrics made and imported from China into Indo-China may be mentioned. The latter may be of interest to French manufacturers.

Lastly a superb collection of " sampots ", dyed and woven entirely by Cambodians, gave a very eastern appearance to this beantiful show.

AGRICULTURAL PRODUCTS; PRESERVING, PACKING, TRANSPORT, TRADE

129 – **Practical Conclusions regarding the Sto age of Tobacco in Bales in Sumatra.** — DEN DOOP, J. E. A., in *Mededeelingen van het Deli Proefstation te Medan-Sumatra*, 2nd Series, No. III, pp. 1-18. Medan, 1919.

Tobacco from two different crops must never be put in the fermenting shed at the same time.

In storing tobacco in bales two processes may be used : —

(1) The tobacco is stored at a distance of 1 to 2 km. from inhabited buildings, in a drying-room with a raised floor.

(2) The tobacco is stored in a building which can be disinfected, with doors and windows covered with fine wire gauze.

Tobacco is never carried in bales from one storehonse to another unless it has been ascertained that it is free from *Lasioderma serricorne* (2).

For 2 or 3 weeks all the tobacco in bales is checked by 2 expert women, who search all day long for the adult the adult *Lasioderma* on the surface of the bales.

Every month a repacking is done, the bales which are the most likely to be moist being opened to see if the tobacco has been infested by the tobacco moth (*Setomorpha margalaestriata*) (2).

130 – **Trial Shipment of Bulk Wheat from Vancouver via the Panama Canal to the United Kingdom.** — BIRCHARD, F. J. and ALCOCK, A. W., in *Department ofTrade and Commerce, Canada* (Dominion Grain Research Laboratory), *Bulletin* No. 1, pp. 1-20. Ottawa, 1918.

Since the opening of the Panama Canal the possibility of shipping bulk wheat from Canada to Europe by this route has been discussed a great deal. It was the opinion of many that the conditions to which the grain would be subjected in the tropics would be found too severe for Canadian grain, and that there would be a grave danger of cargoes arriving at their destination in a heating condition. The Department of Trade and Commerce therefore decided in 1917 when sending a trial shipment that the laboratory should make a thorough investigation of the question.

(1) See *R.*, June 1918, No. 076; *R.*, Nov. 1918, No. 1264; *R.*, Oct.-Dec. 1919, No. 1212 (*Ed.*).
(2) See *R.*, Dec. 1918, No. 1436, and *R.*, Jan. 1919 No. 142 (*Ed.*).

The authors describe in this bulletin the results of their investigations, and give numerous explanatory tables and diagrams. The wheat for this shipment was collected from various points in western Alberta, and was subjected to the necessary analyses for grade, percentage of moisture and weight. The SS. *War Viceroy* was loaded with 99.209 bushels of wheat of 7 different types in such a way that each type which on analysis showed given characteristics formed a layer of the cargo. The vessel was of steel and had wooden flooring and sides in the holds. Without going into details about the method of loading and the arrangement of the cargo in relation to the construction of the ship, the following are the main conclusions arrived at by the Commission in charge of the investigation :—

The chief result is that wheat may be carried from Canada to Europe via the Panama Canal without damage, if the following precautions are taken :

Only wheat which is quite sound in every way should be shipped by this route ; it should be carefully tested for moisture and any lots containing an excessive amount should not be loaded into the vessels. It has not been possible to determine just how much the grain may safely carry, but until some limit is definitely set, a moisture content of more than 14.5 % should be regarded as dangerous.

The temperatures recorded by the thermometers against the false bulkheads near the engine room and stokehole are evidently too high for safety and an unventilated air space of 9 to 12 inches cannot then be considered sufficient protection. When it is necessary to stow grain close to the engine room or stokehole, these spaces should be either ventilated or extended. The records clearly show that it was only in these portions of the holds and close to the propeller shaft tunnel that dangerously high temperatures occurred. The general conditions vary in the different types of ships, but by taking sufficient precautions in the above mentioned respects there will be little difficulty in carrying wheat cargoes safely from Canada to Europe via the Panama Canal.

131 - **American Cotton Seed and Cottonseed Products.** — *United States Commerce Reports*, No. 196, p. 962. Washington, D. C., Aug. 21, 1919.

A preliminary report of the United States Bureau of the Census gives the quantity of cotton seed received at American mills during the 12 months from August 1, 1918, to July 31, 1919, as 4 450 189 tons, contrasted with 4 260 290 tons during the previous year. This does not include 40 438 tons and 31 828 tons on hand on August 1, nor 146 271 tons and 208 358 tons reshipped or burned for 1919 and 1918, respectively. There were 4 366 028 tons of seed crushed during 1919, against 4 251 680 tons during 1918, and 24 599 tons on hand on July 31, 1919, against 40 438 tons on the corresponding date of 1918.

Cottonseed products manufactured, shipped out, and on hand were as follows : —

Item	Year	on hand Aug. 1	Produced Aug. 1 to July 31	Shipped out Aug. 1 July 31	on hand July 31
Crude oil . . . . . pounds	1919	*a*) 16 503 655	1 320 249 788	1 322 507 336	*a*) 25 681 360
	1918	15 477 352	1 312 471 125	1 314 756 603	16 503 655
Refined oil . . . . . do . .	1919	*b*) 265 875 255	*c*) 158 864 979	—	*b*) 146 719 782
	1918	298 757 126	1 188 213 854	—	265 875 255

	1918	6 853	123 663	328 907	11 609
Grabbots, motes, etc. do	1919	12 453	31 480	32 563	11 370
	1918	9 703	56 559	53 809	12 453

a) Includes 3 171 885 and 13 962 704 pounds held by refining and manufacturing establishments and 6 433 196 and 7 077 530 pounds in transit to refiners and consumers Aug. 1 and July 31, respectively.

b) Includes 10 821 959 and 4 569 701 pounds held by refiners, brokers, agents and warehousement at places other than refineries and manufacturing establishments, and 14 230 077 and 7 614 431 pounds in transit to manufacturers of lard substitute, oleomargarine, soap, etc. on Aug. 1 and July 31, respectively.

c) Produced from 1 296 420 913 pounds of crude oil.

During the year ending July 31, 1919 there were imported into the United States 19 057 236 pounds of cottonseed oil, as compared with 16 967 737 pounds during the previous year. Exports of cottonseed products consisted of 174 269 424 pounds of oil, against 109 437 949 pounds; 169 791 tons of cake and meal, against 19 051 tons; and 71 534 running bales of linters against 187 704 bales.

132 - **Exportation of Henequen from Yucatan.** — Rowe, J. W., in *United States Commerce Reports*, No. 111, p. 787. Washington, D. C., 1919.

The total exportation of henequen (1) from Yucatan for the year 1918 is estimated at 600 000 bundles and is valued at 48 000 000 pesos (1 peso = $0.50 United States Currency). For 1919, it is expected that the output will be even greater, owing to the fact now that markets have been opened in various parts of the world, notably in Argentina, where the fibre is used in the manufacture of grain bags.

The henequen commission recently sent a trade commissioner to

(1) Henequen is the fibre of *Agave rigida* var. *elongata*, whilst sisal is the fibre of *Agave rigida* var. *sisalana*. (*Ed.*)

Argentina for the purpose of studying the market there as well as to investigate generally the possibilities of trade between the southern Republic and Mexico. It placed orders, while there, for 50 000 sacks of hennequen and the commission has already dispatched one vessel of its fleet with a cargo of sisal. On its return trip this ship is bringing a cargo of wheat.

The commission is not only concerning itself with the exportation of the raw fibre, but has established factories for the manufacture of sacks and twine, which articles, it is expected, will presently figure extensively among the exports of the State of Yucatan.

MEANS OF PREVENTION AND CONTROL

135 – **Chemical Investigations on Agents for Combating Fungoid Diseases and Insects.** — 1) Mond, R. L. and Heberlein, C., in *Journal of the Chemical Society*, Vols. 115-116, No. 682, pp. 908-922, Figs. 2. Pl. I. London, Aug. 1919. — 2) Ramsay, A. A., in *The Agricultural Gazette of New South Wales*, Vol. XXX, Pt. 6, pp. 428 — 429. Fig. 1. Sydney, June, 1919.

I. — The Chemistry of Burgundy Mixtures. — The mixtures of sodium carbonate and copper sulphate which are the constituents of the above have proved most effective for combating plant diseases of a fungoid character. However, in spite of the highly significant work which has been done by Pickering and Ravaz the authors considered the problem more complicated than the former had assumed, and proceded to carry out investigations on the following lines: 1) The main reactions between copper sulphate and sodium carbonate quantitatively studied with various ratios of the components; 2) the reaction between copper sulphate and sodium hydrogen carbonate; 3) the estimation of the amount of free carbon dioxide and the carbon dioxide in the precipitate, and the ratio cupric oxide CuO: carbon dioxide CO in the precipitates; 4) the solvent action of carbonic acid; 5) the determination of the basic sulphate in various mixtures to ascertain the ratio cupric oxide CuO: sulphur trioxide SO_3 and CuO: CO_2: SO_3; 6) the estimation of the absorbed sodium carbonate; 7) investigations as to the causes and reactions of the change from the colloidal precipitate to malachite.

On mixing copper sulphate with sodium carbonate solution, three distinct copper compounds are formed :— 1) insoluble hydrated basic copper carbonate, which forms the bulk of the precipitate; 2) insoluble hydrated basic copper sulphate; 3) soluble basic copper sulphate. Complete conversion of copper sulphate into these salts is obtained when for 4 gm. of crystal-

lised copper sulphate, 4.25 gm. of crystallised sodium carbonate ($Na_2 CO_3$ 10 $H_2 O$) is added. From the results obtained, there appears to be no well defined compound, the composition altering according to conditions of precipitation. All the compounds are subject to rapid changes, the basic copper carbonate losing carbon dioxide and the dissolved basic copper sulphate soon becoming insoluble.

A 1 % mixture made at 15° C, in 200 litres of water gives :— *a*) basic copper carbonate with CuO and CO_2 in the ratio 2:2 : 1 ; *b*) insoluble basic copper sulphate containing CuO and SO_3 ; ratio 15 : 1 ; *c*) soluble basic copper sulphate equal to 9.6 % of the total copper present ; *d*) free carbon dioxide is evolved equal to 52.4 % of the total carbon dioxide present in the sodium carbonate.

At a higher temperature more carbon dioxide is evolved, until on reaching boiling point, all is expelled and the precipitate is converted into black copper hydroxide.

The whole of the copper precipitate including the normal is at first colloidal sodium carbonate, but the presence of free copper sulphate, sodium hydrogen carbonate, or carbonic acid in the mixture accelerates the change to the crystalline state.

The dissolved basic copper sulphate is in the form of hydrosol.

Changes in the sulphur content of the copper precipitate also take place during the change of the colloid to the crystalloid. The crystalline precipitate contains less carbon dioxide than the colloid. The ratio of CuO : CO_2 in old cristalline precipitate was found to be 2.94 : 1.

The amount of basic copper sulphate formed decreased as the amount of sodium carbonate used was increased ; the free carbon dioxide acts as a solvent on the basic copper sulphate only, not on the basic copper carbonate. The maximum of soluble basic copper sulphate is obtained in a mixture of 4 gm. of copper sulphate and 4.45 gm. of crystallised sodium carbonate and the minimum with 7.38 gm. of the latter. The copper precipitate at 15°C. contains absorbed sodium carbonate in the ratio CuO : $Na_2 CO_3$ = 74 : 1. The whole of the copper precipitate is at first colloidal, and then the gel changes gradually into the crystalline state.

From the results obtained in this research the fact that the chemistry of Burgundy mixture is of a much more complex nature than previously suspected, is confirmed, and there are a number of questions which have to be further elucidated. The nature of the colloid solution, the conditions of its formation and the change to the crystalline state await further investigations, and also the influence produced by small quantities of glue. These all indicate the importance of making further experiments with similar colloids.

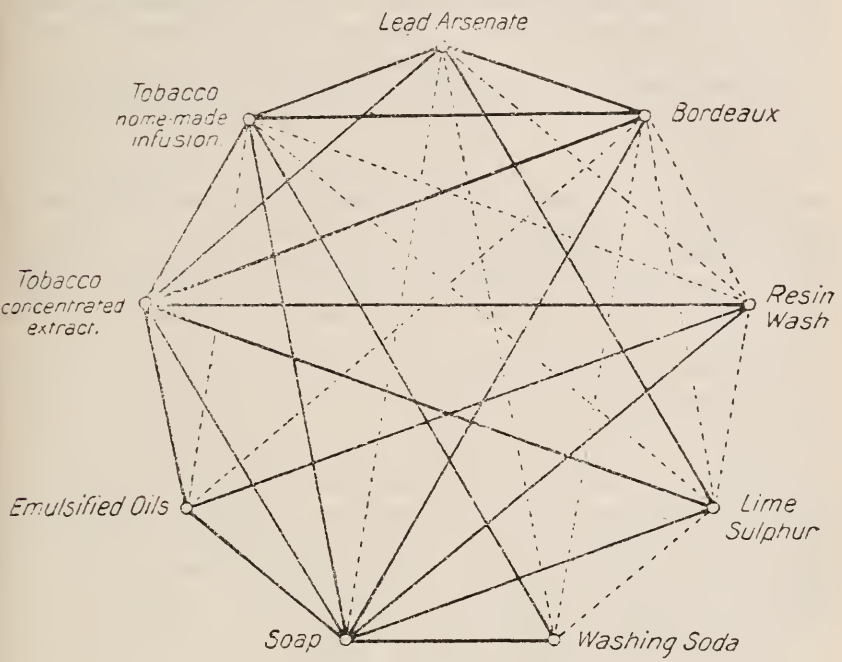
II. The mixing of sprays. — The question of combining insecticides and fungicides in the treatment of orchard pests is attracting more and more attention, for the obvious reason that such combinations may represent substantial savings both in time and money.

The diagram is supplemented by the table indicating what mixtures may safely by made and also the unreliable sprays.

Table of Compatible and Non-compatible Sprays.

Spray	May be mixed with—	Must not be mixed with—
Alkali sulphides (liver of sulphur)	Soap, washing soda	Bordeaux, Burgundy, lead arsenate, Paris green.
Ammonia copper carbonate	Tobacco infusions, concentrated tobacco extracts	Bordeaux, Burgundy, lead arsenate, Paris green.
Bordeaux mixture	Lead arsenate, Paris green, concentrated tobacco extracts, tobacco infusions soap	Alkali sulphides, lime-sulphur, certain oil emulsions, resin wash washing soda.
Burgundy mixture	Concentrated tobacco extracts	Alkali sulphides, lead arsenate, lime sulphur, Paris green, resin wash, soap, washing soda.
Ferrous sulphate and sulphuric acid	To be used alone	
Iron sulphide	Bordeaux, lime-sulphur	
Lead arsenate	Bordeaux, lime-sulphur, sulphur (atomic), concentrated tobacco extracts, tobacco infusions.	Ammonia copper carbonate, alkali sulphides, resin wash, soap, tobacco infusions, washing soda.
Lime-sulphur	Iron sulphide, lead arsenate, concentrated tobacco extracts	Bordeaux, Burgundy, resin wash, soap, tobacco infusions, washing soda.
Paris green	Bordeaux, concentrated tobacco extracts.	Alkali sulphides, ammonia copper carbonate, resin wash, soap, washing soda.
Resin wash	Kerosene emulsion, concentrated tobacco extracts	Bordeaux, Burgundy, lead arsenate, lime-sulphur, Paris green, tobacco infusions.
Soap	Alkali sulphides, Bordeaux, tobacco infusions concentrated tobacco extracts, resin wash, washing soda.	Burgundy, lime-sulphur, lead arsenate, Paris green.
Sulphur (atomic)	Lead arsenate, Paris green.	
Soap-oil emulsions		Lead arsenate.
Tobacco extracts, concentrated	Ammonia copper carbonate, Bordeaux, Burgundy, lead arsenate, lime sulphur, oil emulsions, resin wash, soap, tobacco infusions, washing soda	
Tobacco infusions	Ammonia copper carbonate, alkali sulphides, lead arsenate, soap, concentrated tobacco extracts, washing soda.	Lime-sulphur, lead arsenate, Paris green.
Washing soda	Alkali sulphides, emulsified oils, soap, concentrated tobacco extracts, tobacco infusions.	Burgundy, Bordeaux lead arsenate, lime-sulphur, Paris green.

Diagram indicating the Compatibility and Incompatibility of Orchard Sprays:



Circles connected by a thick black line may be mixed together.

138 – ***Bacterium Solanacearum* Injurious to Beans in Florida, United States.** — SMITH, F. and MCCULLOCH, L. in *Science*, New Series, Vol. L, No. 1288, p. 238, Lancaster, Pa., Sept. 5, 1919.

DISEASES OF VARIOUS CROPS

In June, 1919, the authors received for examination some badly diseased bush beans from Lynn Haven, Florida. The leaves were wilted and more or less brown. Often the petioles also were brown and wilted to their base. The roots were brown and the epidermis somewhat decayed in places. The woody parts of the plant, both stems and roots, had dark stained vascular bundles. Cross sections examined microscopically showed from 50 to 100 per cent. of the vessels to be full of bacteria and no fungi were visible. As the discolouration of the leaves was generally uni-

form, with no lesions apparent, while the roots showed lesions and contained bacteria in great numbers, the supposition was that the disease must be due to the bacteria and that they must have entered through the root system. The loss in the Florida field was about 20 % of the beans planted.

Agar-poured plates gave pure cultures of a white bacterial organism having all the characteristics of *Bacterium solanacearum*.

Cultural work in other media and needleprick inoculations made with sub-cultures of colonies taken from the poured plates confirmed this diagnosis.

A number of different legumes was inoculated by pricking the bacteria into the stems. Of beans, Waxbush, Red Valentine and Refugee proved very susceptible. These plants began to wilt two days after inoculation and a number were entirely wilted and fallen over in 7 days. In addition, good infections were secured in Lima beans (Fordhood variety), Pinto beans (a brown speckled variety) and Great Northern (a white Navy bean).

Inoculated in peas, this parasite acts more slowly than in beans, but it is not without pathogenic properties at least in some varieties. Following stem inoculation there is a slow drying and shrivelling of the leaves, but not a sudden wilt. The plants become stunted. Cross sections of the stems show bundles discoloured and containing bacteria, though in less abundance than in infected beans, tobaccos, or tomatoes. Telephone, Little Marvel and Mammoth Luscious Sugar were the varieties of peas that became infected. The organism has been re-isolated from both beans and peas, and proved to have the same characters and infectiousness (tested on tobacco and beans), as the original culture.

The organism was also found to be infectious to soya beans (variety Sto San) and to cowpeas (variety Black Cow).

Tobacco and tomato plants used for control showed typical *Bacterium solanacearum* infections.

So far as known, this is the first time the disease has been observed in beans, peas, soya beans or cowpeas, although known to occur in groundnuts, in *Mucuna* sp. and in some other legumes. Fortunately, beans appear to be very susceptible only in the early stages of growth.

139 - ***Erisyphe Risi* (=*E. communis*), Injurious to Peas, in Brazil.** — See No. 28 in this *Review*.

140 - ***Podosphaera Oxycanthae* var. *tridactyla*, an Erysiphe Injurious to the Bay Cherry, in Switzerland.** — FISCHER, ED., in *Schweizerische Obst-und Gartenbau-Zeitung*, No. 20, pp. 314-315, 1 fig. Munsingen, Oct. 15. 1919.

In a closed-in part of the Botanic Gardens at Berne there grow various large specimens of *Prunus Laurocerasus* These were damaged by frost during the winter of 1918-19 and were severely pruned back, in consequence of which new shoots sprouted and were still growing even at the end of the succeeding summer. Up to August and September they showed young pale green leaves.

At the beginning of September, the author found that on many of these twigs the youngest and uppermost leaves were more or less shrunken up and coloured whitish yellow on their lower surface : in addition, they often kept exceptionally small. The lower side was covered with a white fungous layer, while the lower leaves with no change in their shape appeared to be only slightly or not at all affected.

The same alterations in the early stage were also observed by the author on a specimen of *P. Laurocerasus* growing in the open in another part of the Botanic Gardens ; this plant had also been cut back to near the stump and was already covered with new branches.

Further examination of the diseased leaves proved they were attacked by *Podosphaera Oxyacanthae* var. *tridactyla*, an erysiphe parasitic on different species of *Prunus*, even outside Switzerland, but apparently not yet widely reported, either in Switzerland or elsewhere, on *Pr. Laurocerasus*.

The unusual appearance of the fungus on the bay cherry might be explained, according to the author, by the fact that, in the cases studied by him, contrary to the usual, when the erysiphe was growing on other species of *Prunus* the bay cherry had leaves still in the tender state and on that account liable to infection.

As these conditions, however, only seldom occur, it is not likely even in the future that the disease can spread to a great extent on the bay cherry. This does not exclude the possibility that the fungus. once established on *P. Laurocerasus*, may subsist on it and by means of hibernating perithecia or by the hibernating of its mycelium inside the buds attack also the young wood growing at the normal period. It is adivisable therefore to remove and destroy the young diseased twigs and see to the destruction of the leaves which fall from infected branches.

141 - **New Fruit Fungi Found on the Chicago Market.** — TURLEY, H. E., in *Science*, New Series, Vol. L., No. 1294, pp. 375-376. Lancaster, Pa., October 17, 1919.

Three new fruit diseases have been found on the Chicago market :— *Botrytis* sp. on apples, *Polyscytalum* sp. and *Fusarium* sp. on grapefruit.

Botrytis sp. was first isolated from Spitzenburg apples and later found on Arkansas Black and Winesap. Five Spitzenburg apples affected with the disease were taken from the same box. These affected apples were entirely rotted. They were very soft, but the rot was firmer than that produced by *Penicillium*. Within the author's knowledge no *Botrytis* of the description given by him from examination has ever been recorded. In the same culture tube occupied by this *Botrytis* the perfect stage of the fungus developed, but during the four months when it was kept under observation no ascospores were formed. Inoculation of Spitzenburg apples with conidiospores gave positive results.

Polyscytalum was found on the market only three times and as yet is not a disease of importance. The fungus was isolated from a slightly sunken soft area, of a little lighter colour than the grapefruit itself. In the early stages of the disease the rot works down to the pulp of the fruit in a perpendicular manner. The affected tissue is very soft, more so than

that attacked by *Penicillium*. When a spot produced by the action of the fungus has reached the diameter of 20 or 25 millimetres, the parasite begins to attack the pulp of the fruit, which soon all becomes a soft mushy mass. Positive results were obtained from inoculations.

Fusarium sp. was first found in a shipment of Florida grapefruit. The fungus was found enough on the Chicago market to classify it as a disease of economic importance. The isolation was made from a tan to reddish brown rough sunken area an inch in diameter. The tissue underneath was dry, corky, and of a tan colour extending inward. The spots often reach a greater size than that just indicated. In the case of the larger spots the fungus often develops down into the pulp of the fruit causing a rot. A very fine white cottony growth often develops in the pulp of the fruit and sometimes on the surface of the brown rough area. Inoculations carried out gave positive results. It has been shown that a *Fusarium* spot develops very slowly. However, in 50 % of the inoculations, when a spot had reached a diameter of 20-25 mm, a rot developed at the edge of the sunken area. When *Fusarium* acts in this manner it is very serious, for a grapefruit will be a worthless rotten mass within forty eight hours after the rot has started.

142 – **Experiments with Tumours caused by Bacteria in Pines.** — DUFRENOY, J., in *Comptes rendus des séances de l'Académie des Sciences*, 2nd Half 1919, Vol. CLXIX, No. 12, (22 Sept. 1919), pp. 545-547. Paris, 1919.

At Bareges (in the upper Pyrenees Department), *Pinus sylvestris* and *P. Laricio* are deformed by resinous swellings of bacterial origin, identical with those on the maritime pine (1) and, as experiments have shown, transmissible from tree to tree.

The action of the *Coccus* on the pine, while at first stimulating, brings on the develpment of hyperplasia, cells filling up air spaces or canals, sacs especially on the border of medullary rays. Finally there follows the resinous liquidation of the tissues.

INJURIOUS INSECTS AND OTHER LOWER ANIMALS.

MEANS OF PREVENTION AND CONTROL

143 – **Legumes of the Genus *Deguelia (Derris)* and Their Use in Checking Insects and Other Injurious Invertebrates.** — MC INDOO, N. E., SIEVERS, A. F., and ABBOTT, W. S. in *Journal of Agricultural Research*, Vol. XVII, No. 5, pp. 177-200. Washington, D. C., August 15, 1919.

The genus *Deguelia* Aubl. — synonymous with *Derris* Lour. — belongs to the leguminous family and includes several species already found to be insecticides or poisonous; the ground roots of one species, probably *Deguelia elliptica* (Wall.) Janb. — synonymous with *Derris elliptica* (Wall.) Benth. — are sold as an insecticide ; *D. elliptica* is a strong fish poison and is much used in the East Indies for catching fish.

(1) See *R.* May 1918, No. 600. (*Ed.*)

Of the different insecticides on sale, some act on the stomachs of insects affected, others by contact; the authors show that powdered roots of *D. elliptica* and of *D. uliginosa* (DC) Baill. — syn. *Derris uliginosa* (DC) Benth. — act at the same time in both ways, but are of no value as fumigators.

The authors studied the following materials: — powdered roots of a species of *Derris*, probably *D. elliptica* bought on the market; roots of *D. elliptica* called "tuba,, or "toeba,, in the Dutch East Indies, from Buitenzorg (Java); stems of *D. uliginosa* from Suava (Fiji Islands); stems of *D. Koolgibberah* Baill. and of *D. oligosperma* from Brisbane (Queensland, Australia); roots of *D. scandens* Benth., and roots and stems of *D. robusta* Benth. from Sibpur (Calcutta, India).

On extraction with boiling denatured alcohol, they obtained from these substances the following percentages of extract: respectively 14.25,8.50-8.50, 10.30,22. 50,20.30,16.70 (roots of *D. robusta*) and 15.70 (stems of same species). Of the 6 species tried, only two, *D. elliptica* and *D. uliginosa*, were found satisfactory for use as insecticides.

Several writers state that the toxic principle of the *Deguelia* species is a resin that acts on the different classes of animals according to the development of their nervous system. It kills some insects easily, others with difficulty, but usually its action is slow and it apparently causes death by paralysing the motor organs. The extract obtained with denatured alcohol applied in the form of a spraying mixture has proved effective on certain aphidae (*Myzus persicae, Macrosyphum liriodendri, Rhopalosiphum pseudobrassicae, Aphis helianthi, A. gossypii, A. spiraecola*), and on larvae of *Leptinotarsa decemlineata* and the small caterpillars of *Hyphantria cunea*. It is possible to incorporate extracts of *D. elliptica* and *D. uliginosa* in soft soap; by simply dissolving them in plenty of water a solution ready for spraying. can be obtained.

It has been found that commercial *Derris* sp. powder as ordinarily used is efficacions against dog fleas (*Ctenocephalus canis*), chicken lice (several species of Mallophaga), the house fly, 3 species of aphis (*Aphis rumicis, A. pomi, Myzus persicae*), the larvae of *Leptinotarsa decemlineata* and the small caterpillars of *Hyphantria cunea*, but it is of no practical value against bedbugs (*Cimex lectularius*), roaches (*Blattella germanica*), chicken mites (*Dermanyssus gallinae*), mealy bug of lemon and orange trees (*Pseudococcus citri*), *Orthezia insignis, Tetranychus bimaculatus*, larvae of *Lepidosaphis ulmi*. Used as a powder in suspension in water, with or without soap, under practical conditions, it was effective against most of the aphides tried, and against the caterpillars of *Autographa brassicae, Datana ministra, Asinota senatoria, Malacosoma americana* and the larvae of *Leptinotarsa decemlineata*.

144 – **Chemical Studies on Insecticidal Products.** — See No. 135 in this *Review*.

145 – **A New Insecticide and Anti-fungoid Mixture for Vines.** — BERTHELOT, A., in *Revue de Viticulture*, Year XXVI, Vol. LI. No. 1321, pp. 266-267. Paris, October 23, 1919.

In order to control at the same time animal and vegetable pests on

vines and to avoid also the drawbacks resulting from the use of lead, the author recommends the use of an intimate mixture of 448 parts trisodium arsenate with 74.9 of sulphate of copper in a suitabie volume of water. The ingredients of this solution are calculated so as to obtain a fairly neutral mixture. It is easy to vary at will the reaction of the mixture by altering the proportion of sulphate of copper, a slight excess of which would not be injurious.

Such a compound has been successively applied on a series of vineyards, mostly in the Aude and Haute Garonne, and the experiments were entirely satisfactory.

Used in increasing doses corresponding to 2,3 and up to 4 kg. of arsenate of copper per 100 litres, even in high concentration it causes no damage or burning to vegetation. It showed great adhering properties on leaves and grape-bunches.

The number of larvae destroyed was very great, and any surviving larvae were generally in a dying condition.

Naturally, in order to obtain quite satisfactory results, at leat two applications are necessary, one on the appearance of the insects (" cochylis " or " eudemis "), which coincides more or less with the flowering of the vines ; the other eight to ten days after. The strength of the mixture should be at the minimum rate of 20 gm. arsenate of copper per litre of water.

146 - **The Control of Locusts in the Capitanata, Italy** (1). — PAOLI, G., in *La Propaganda Agricola*, 2nd Ser., Year XI, No. 15, pp. 184-187. Bari, 1919.

The locusts (*Dociostaurus maroccanus*) which multiplied in large numbers during 1919 in the province of Foggia (communes of Foggia, Ascoli Satriano and Troia) were combated by the author with sprayings and with poisoned bran.

When the insects were still in the wingless stage sprayings were carried out with a solution of arsenite of soda in proportions varying from 0.75 to 2 % according to the age of the insect. Eighty-six knapsak sprayers of the ordinary type used in treating vines and as recommended by the Ministry of Agriculture, were carried out for this purpose ; about 5000 hectolitres of solution and 75 quintals of arsenite of soda were used in 34 days. The effect of such spraying is very quick ; one hour after, most of the insects wetted by the jet are dead.

The bran was also poisoned with a solution of arsenite of soda in the proportion of 4 to 6 % ; it was moistened so as to make it absorb about its own weight of solution. In the mechanical preparation of this remedy, advisable in order to avoid all or nearly all the drawbacks involved in hand mixing, a special simple and compact apparatus was used as invented by the author and based on the principle of allowing the bran and the poisonous solution in fine subdivision to drop from a height so that they

1) See *R.*, Nov. 1918, No. 1311; *R.* Apr. No. 543. Cf. also *The Control of locusts in different countries* Internat. Inst. Agric., Rome, 1916. *passim.* (*Ed.*)

combined during the fall. The bran was spread by hand on columns of locusts. The mortality was extraordinary, beginning after a few hours and continuing for two or three days. The quantity of bran used in 1919 was 740 quintals.

An experiment executed by the author with zinc phosphide in powder form, scattered alone or mixed with wheat flour, on the herbage on which the locusts had to feed, with the ordinary blowers used to sulphur vines, showed that this method — which does not appear to have been used yet by others against insects in the open — might give useful pratical results if the phosphides were reduced to an impalpable powder and used against very young insects collected on slopes of short grass wet with dew. Compared with sprayings, phosphide offers the following advantages:— 1) Rapidity of application and consequent economy ; 2) suppression of water carrying, which costs most ; 3) diminution of labour required ; 4) possibility or even opportunity to work when the herbage is wet with dew or rain ; 5) phosphide does not dry up the grass, which thus remains always edible for the locusts.

The author also intended to try crushing the insects by compression using plough tractors, with very large wheels or ordinary rollers used for roadmaking, but this experiment could not be tried, no machine of the kind being to hand at the proper time.

147 - **Experiments in Checking the Migrating Cricket (*Schistocerca tatarica*) in Algeria** — BAZILE, G., in *Comptes rendus des séances de l'Académie des Sciences*, 2nd Half-year 1919. Vol. CLXIX, No. 12 (Sept. 22 1919) pp. 547-549. Paris, 1919.

The results are described of experiments made in Algeria (Department of Algiers) against *Schistocerca tatarica* with the flame-throwers and poison gases already used in France to keep down the Moroccan cricket (*Dociostaurus maroccanus*) (1).

Flame throwers (Army model P3). — In uncultivated districts the operator, kneeling, sweeps the ground occupied by the moving crickets with the flame jet. All insects reached by the flame or within a metre of the zone covered are instantly destroyed. Others further away move off, but with difficulty, and then are killed also. The crickets are destroyed either by the flame or by the heat only, or by the combustion products of the heavy coal oil.

The effectiveness of this method is still greater against insects at the transformation stage, as they move about less. Besides, the operator works in an upright position and makes more rapid progress. Shrubs infested with crickets receive two or three blasts of the flame, and when they catch fire they increase and prolong the action of the treatment. Practically no insects escape destruction.

The treatment was carried out in the morning very early, so as to catch the insects while still numbed by the coolness of the night.

In six days several million insects were destroyed.

---

(1) See *R.*, July-Sept., 1919, No. 1049, (*Ed.*).

To clear trees without killing them, they were sprayed with oil transformed into fine drops by the apparatus. The insects appeared to be so paralysed that they fell from branch to branch, not without trying to get a hold, to the ground where they died. This the way in which the apparatus should not be used except where normal treatment is impracticable, as it consumes much oil and consequently is more burdensome.

The flame-thrower treatment requires about 700 litres of oil per hectare and costs from 300 to 400 francs. It seems at first very expensive, but the great speed makes it clearly better than all processes hitherto, used, and it acts best either on the laying places at hatching time or columns of insects when just forming, or again among bushes where the crickets collect before undergoing transformation.

Poison gases. — A mixture of carbon oxychloride and tin chloride was tried on the bottom of a ravine where the crickets were collected in large numbers. The insects on shrubs were not affected but the young ones on the ground were quickly killed.

This process, which makes use of a large amount of bulky material, involves risks not only to the operators but also to people or animals near by, as well as to vegetation. It could be employed only in the southern desert belts.

148 – **The Destruction of the Rice Weevil with Chloropicrin** (1). — BERTRAND, G., BROCQ-ROUSSEAU and DASSONVILLE, *in Comptes rendus des séances de l'Académie des Sciences*. Vol. CLXIX, No. 19 (Nov. 10 1919), pp. 880-882. Paris, 1919.

These investigations were made on the rice weevil (*Calandra oryzae* Ls.) which is very prevalent in maize grains.

The authors first examined the effect of poisonous vapour on the weevil outside the grain, using the same methods as in their researches on bed bugs (2) ; 560 specimens were utilised. The subjoined table shows the results arrived at in 4 series each including 14 experiments. The volume of the flask was of 8 litres, and the temperature between 20 and 27° C.

The authors tried to find by means of these results the conditions under which, in practice, the weevils contained in grain could be destroyed. One hectolitre of infested maize which they used had an apparent density of 0.715 and included 62 litres of actual grain and 38 of interstitial air. If it had been necessary, in order to kill the weevils, only to vaporise the proportions of chloropicrin indicated in the annexed table, a few grammes of this substance per hectolitre would have been sufficient. The insect, however, is sheltered inside the grain and the latter holds, at least for a time, a small proportion of the poison vapour. Hence it is necessary, as the experiments demonstrate, to use more chloropicrin in order to kill the weevils contained inside the grain than to kill those outside.

By varying the conditions of experiment, the authors saw that the quantities required vary appreciably according to circumstances, such as: depth of the layer of grain, duration of contact with chloropicrin vapour, temperature, etc.

Direct treatment of the grain in bags, which is at once the most practical and difficult method, was successfully carried out in consequence of the authors' experiments: — by pouring from 20 to 25 gm. of chloropicrin on to each bag lying on the ground in a closed chamber, twenty hours were long enough to ensure the death of all weevils, at a constant temperature of 10-12° C. The insects killed were almost all outside the grain ; they may easily be got rid of by winnowing, and the grain may be fed to stock.

This method being very simple and effective ensures at once and at the same time the destruction of the insects which manage to get out of the grain and hide in cracks of the wall or floors in the chamber where the treatment is carried out.

149 – ***Ampera intrusa*, n. gen. and n. sp., a Rhynchote Discovered among Rice Grain in Store, in Java.** — DISTANT, W. L., in *Bulletin of Entomological Research*. Vol. X, Part. I, p. 41, 1 fig. London, Nov., 1919.

INSECTS, ETC. INJURIOUS TO VARIOUS CROPS

Under the name *Impera intrusa*, a (family *Lygaeidae*), discovered by Dr. C. J. J. VAN HALL in Java among rice in a warehouse, is here described as representing a new genus and species.

150 – ***Phthorimaea operculella*, a Microlepidopteron Injurious to Potatoes in Sicily, Italy** (1). — BORZÌ, A., in *Bollettino di Studi ed informazioni del R. Giardino coloniale di Palermo*. Vol. V, No. 1-2, pp. 35-38. Palermo, 1919.

Recently the presence of *Pythorimaea operculella* Zell. was reported in potato tubers grown near Palermo.

A description of the insect is given, accompanied by biological notes and an indication of the most effective means of control.

151 – **The Chief Insects Injurous to Sugar Cane in Fiji.** — VEITCH, R., in *Bulletin of Entomological Research*, Vol. X, Part 1, pp. 21-39. 8 figs. London, Nov., 1919.

While awaiting the publication of the final results of his investigations begun in 1914 on the insects causing serious damage to sugar cane in the Fiji Islands, the author enumerates the more important species observed chiefly in the districts of Lautoka, Rarawai, Nausori (Viti Levu) and Labasa (Vanua Levu). He also gives biological notes on each of these insects and indicates the control measures adopted. The chief varieties of cane grown in the zone where the investigations were carried out are Badila, Malabar and Pompey.

The insects injurious to cane which were examined are :—

Rhabdocnemis obscura Boisd. (cane beetle borer) ; *Trochorrhopalus strangulatus* Gyl. (small cane beetle borer) ; *Rhopaea vestita* Arrow (white grub of sandy soils) ; *R. subnitida* Arrow (white grub of alluvial and red hill soils) ; *Adoretus versutus* Har. (rose beetle) ; *Simodactylus cinnamomeus* Boisd (sugar cane wireworm) ; *Lacon stricticollis* Fairm. (yellow wireworm) ; *Cirphis unipuncta* Hawd. (sugar cane army-worm) ; *C. loreyi* Dup. (sugar cane army-worm) ; *Trachycentra chlorogramma* Meyr. (moth borer of cane); *Cosmopteryx* n. sp. (cane leaf-miner) ; *Perkinsiella vitiensis* Kirk (leaf hopper) ; *Aleuroides comata* Mark. (cane aleurodid) ; *Pseudococcus bromeliae* Bouché (cane mealy bug) ; *Locusta danica* L., *Cyrtacanthacris guttulosa* Walk.

152 – **Insect Pests of Tobacco, in India.** — See No. 54 in this *Review*.

153 – **The Coleopteron *Lasioderma serricorne* and the Lepidopteron *Setomorpha margalaestriata* Injurious to Stored Tobacco, in Sumatra** (1). — See No. 130 in this *Review*.

154 – **The Earwig (*Forficula auricularia*) as a Pest on Pear-tree Leaves, in Switzerland.** — STAUB, W., in *Schweizerische Obst und Gartenbau-Zeitung*, No. 20, pp. 313-314. 2 Figs. Mönsingen, Oct. 15, 1919.

This orthopteron, which is very common and well known as an eater of many kinds of food — it feeds on animal and vegetable matter — has recently been recognised as capable of causing serious damage to the leaves of the pear tree.

At the beginning of June, 1919, a very young wall pear-tree growing on a wooden partition in a garden near Berne appeared, even from a distance, to have its foliage severely injured by insect attack. One part had only the skeletons and ribs of its leaves remaining, and many of the other leaves were more or less riddled with holes and nibbled round their edges.

Examination of the leaves and branches during the daytime showed no trace of the agent causing the damage, but at night an inspection of the young tree revealed a large number of larvae of *Forficula auricularia* L. busy at their work of destruction. Also on the wooden wall and on the metal wires used to support the branches many larvae were found which were trying to get on to the leaves.

(1) Cf. *R.*, Dec. 1918, No 1436, (*Ed.*)

A score of specimens captured on the leaves and put in a vessel were fed with still intact fresh leaves, plucked from the tree in question. The insects produced on these leaves the same kind of damage as described above on the leaves in the open.

Careful search and destruction of the insects carried on for two consecutive days was sufficient to preserve the foliage from further damage. In addition, a period of showery weather which happened at this time helped to clear away the insect.

155 – ***Stenolechia gemmella*, a Microlepidopteron injurious to Oaks in Switzerland.** — BARBEY, A., in *Journal Forestier Suisse*, Year LXX, Nos. 9-10, pp. 129-131. 1 Pl. Berne, Sept.-Oct., 1919.

Stenolechia gemmella L. (*Poecilia nivea* Han.). the appearance of which had previously been reported in Switzerland, spread during 1919 from one end to the other of the country on *Quercus Robur* L. var. *pedunculata* (Ehrh) and var. *sessiflora* (Salisb.)

As a result of attack by this partasie the oak branches thickened for a length of 2 to 6 cm. at their ends. A longitudinal cut on one of these branches showed in the interior the small caterpillar of the insect boring an irregular tunnel having more or less pronounced strictures.

On the basis of observations made so far, the author has come to the conclusion that the insect produces only one generation a year.

If a certain proportion of terminal buds dry up, there will obviously be a considerable loss in growth.

Possibly the invasion of *S. gemmella* may still continue in 1920, perhaps over a wider area, but it is to be expected that a year or two hence this insect will disappear ander the influence of adverse natural causes.

156 ***Lithocolletis platani*, Microlepidopteron injurious to Planes in France.** — *Bulletin de la Société entomologique de France*, No. 15, pag. 262. Paris, 1919.

M. P. VAYSSIÈRE states that the leaves of planes at Fontainebleau and neighbourhood, were attacked by the mining caterpillar of *Lithocolletis platani*, a microlepidopteron considered as indigenous further south. Some of the leaves examined showed signs not only of mines containing the young caterpillars but also of empty pupa cases ; this fact suggest the existence of a summer generation of the parasite.

The Rearing of Donkeys and their Crosses with Horses in Italy and her Colonies.

By Professor ETTORE MASCHERONI
Lecturer in Animal Husbandry at the Royal Higher School of Veterinary Medicine of Turin.

DONKEYS.

ITALY. — Donkeys appear to have been first imported into Italy by the Illyrian tribes, and perhaps even before then by the Cumans at the period of the foundation of Cuma in the island of Ischia. The rearing of donkeys is not uniformly distributed over the country, as it is seldom carried on in the north, but more extensively in the centre and still more in the south of the peninsula and in the islands of Sicily, Pantelleria and Sardinia.

In 1918, Italy had 949 162 donkeys and in this respect ranked immediately after Spain. The distribution was as follows: —

Piedmont	15 922 head	Abruzzi and Molise	86 283 head
Liguria	10 305 »	Campania	133 039 »
Lombardy	44 268 »	Apulia	55 283 »
Venetia	38 666 »	Basilicata	34 226 »
Emilia	35 595 »	Calabria	79 164 »
Tuscany	59 169 »	Sicily and Pantelleria	205 099 »
Marches	16 041 »	Sardinia	37 601 »
Umbria	36 088 »	In the army	4 565 »
Rome (Latium)	57 398 »		

The donkeys in Italy are of the following breeds: — *Apulian, Sicilian, Pantelleria* and *Sardinian*. Only the first three are used for mule breeding.

The Apulian donkeys include the sub-breeds of *Lecce* or *Martina Franca*, of the *Marches*, of *Romagna*, of *Basilicata* and of *Calabria*. The Sicilian includes two sub-races, that of the *eastern provinces of the island* (chiefly Syracuse, and next Catania) and that of the *western provinces* (chiefly Trapani, Palermo and the littoral of the provinces of Girgenti and Caltanisetta) (Tucci).

The *Apulian* breed is tall, with a long, well-proportioned body. The height may be of 1.45 metres or over. The head is large; eyes rather small; ears long, wide, hairy and lying nearly horizontally; mouth not very big; nostrils not very open; jaws large and throat region narrow. The neck is large at its base and well fixed to the head; the back straight; hind quarters well made; limbs robust; joints very visible; hoofs fairly big; coat generally dark but sometimes grey. Hair smooth, seldom curly; hair of the tail abundant; hair on fetlock and coronet of some length but shorter than in the Poitou type.

" These points are common to the four breeds named, but are in greatest harmony in the *Martina Franca* breed, which is also the largest; they vary a little in donkeys of the Marches, Basilicata, and Calabria, and are less in harmony in the Romagna breed " (Tucci).

The *Pantelleria* type is of great importance for cross breeding in Italy The island of Pantelleria (the ancient Cossyra), situated midway between the Sicilian and African coasts, has always been famed for its donkeys which, although of purely African origin, have a faint resemblance in general appearance and in colour of the coat to the so-called European donkey.

Tucci, who has specially studied the donkeys of this island, states that the grey coat has almost disappeared from among them, as the preference is all for a black coat with white muzzle and white or grey hair under the belly and on the inner side of the thighs. " The stripes of dark hair on shoulders and withers have also disappeared naturally, in consequence of choosing breeding animals with a uniform coat, preferably dark bay or quite black. The Pantelleria breed has also other special points: — Quick gait and sure-footedness on steep slopes, over pebbles and stones of all shapes and sizes; a natural tendency to an ambling pace which gives the animal a greater market value and makes it one of the best for riding on; quick growth, so that yearlings are already excellent beasts of burden; endurance on long journeys with a load of 3 to 4 cwt. on its back. The hardiness of these animals is exemplary and their sobriety extraordinary. They eat anything, and at vintage time some of the refuse unsaleable grapes are kept for them. With this food and at this season, if the owners of the animals have means to treat them better, the animals show the effects of more liberal diet and grow fat, while the coat becomes very bright and their energy and spirit become even more evident. The temperament of the Pantelleria donkey is "nervous-sanguine", though it comes under the class of large-sized animals, which is not common in donkeys of the other parts of Italy and abroad, intended for mule breeding.

" These animals are agile and lithe in form; the legs are slender, muscular and dry. By " slender " I do not mean they lack proportion as a whole,

as this point is a distinctive feature about the animal and indicates neither weakness nor deficient development of the bony foundations of the limbs. The back is almost always straight; the croup is often well shaped, especially in the female ; the fore quarters are well made : the head is light ; the ears are relatively short, very mobile and always borne straight ; the foot is big, admirably shaped, and the hoofs are so hard that they do not need shoeing. The hair is always short and smooth, seldom curly. The height varies from 1.28 to 1.40 metres ". (Tucci).

Unfortunately this excellent breed is small in numbers, amounting to barely a thousand head.

The *Sizilian* donkey has points which separate it from the Apulian, but which do not attain the elegance and perfection of the Pantelleria breed. Whereas the type from the eastern districts is more like the Apulian, that from the western and southern parts has rather more resemblanee to the Pantelleria type.

The height on the average is 1.35 metres, with chest measurement of 1.65 m. and girth of front legs 0.175 m. ; the coat is grey ; head well proportioned and with slightly rounded profile ; ears long and straight ; neck large ; back straight ; hind quarters somewhat sloping ; tail with fairly long hair ; limbs strong and hoofs well shaped.

The *Sardinian* donkey is very small (0.80 to 1 m.), with brown or dark coat, rarely light and with the cross mark ; head too heavy for size ; ears long and straight ; neck and shoulders weak ; mane scanty and darker than coat ; chest sufficiently developed (from 1.10 to 1.20 m. round) ; back straight and robust ; limbs well formed, sturdy and furnished with excellent hoofs ; tail long, with little hair.

It is used as a beast of burden and often as a draught animal, but it is also used to turn mill-stones, hence the name " *molentes* " given to these animals by the Sardinians.

The feed consists of straw, beans, barley and hay when there is any. When not at work the animals are sent to grass, and a single herdsman looks after the donkeys of the district, collecting them by trumpet call (Galbusera).

The chief rearing districts in the province of Sassari are Padra, Pozzomaggiore, Alà dei Sardi, Marca Romana, Villanova, Monteleone and, in the province of Cagliari, Campidano di Oristano and Iglesiense (Faelli).

For this animal no fairs, markets or exhibitions at all are held.

Colonies.— *Libia.* — The donkeys of Libya are of small stature, mostly brown coated, almost white at the muzzle and belly, and round the eyes.

Of the donkeys of Tripoli, Pucci and Gugnoni say : " Their chief distinguishing points are their lack of height (95 cm. on the average) and their extraordinary thriftiness.

They are well proportioned and clearly distinguishable from the small, thick-set Sardinian animals ; in form they resemble most the Abyssinian breed. Inland the donkeys have a grey coat with the mule stripe more frequently than those at the coast perhaps, but the predominating colour is always brown, more or less dark, with typical light areas on the belly,

on the inner part of the thigh and round the eyes and mouth. Ther are also, however, completely black specimens. The incision made b the Arabs in the nostrils of these poor beasts, with the idea of thus facilita ting breathing, is less common we think, in the interior than at Tripoli Another very strange operation is that of piercing the tips of the ears o young donkeys and tying the tips close together to improve their appearance

" Not only in the streets of Tripoli but also in the Djebel other breed are met with, but which are of greater height, proving that the importatio of individuals of other breeds must have been made for a long time and t some extent. At Djebel Garian and at Djebel Ferrigna we measure some of these, and their height was over 130 cm. at the withers. Th natives state that the crosses between the small local breed and the im ported donkeys are highly valued, as these have the thrift and enduranc of the small African types, and also the advantage of greater size and conse quently greater strength. Old Arabs at Garian assured us that the introduc tion of other breeds of donkeys into their country and the presence of cros ses are not events of recent date but go back to the middle of the 19t century at least. Further in the interior, for example, the tribes of Orfell and Oulad Bouchef possess only small donkeys.

Erithrea. — MARCHI say that the *Erithrea* donkeys have analogies wit the *Abyssinian* and *Nubian* breeds, including the *Etbai* types, and he add — " The Abyssinian breed includes almost all the donkeys in the Colony It lives on the plateau, the low plain on the east, the Sahel, the weste slopes of the plateau and is also distributed over the Gasc residence an Setit and Barca. There are also, it is true, many Etba and Kassala speci mens, but they are few in comparison with the first.

" The *Abyssinian* is of slate-grey colour, seldom brown. It has th mule stripe and the cross mark, and fairly often zebra stripes to the kne or hock. During the " keremly " (rainy season) the hair becomes long and o a more definite grey, which turns to rust colour during the " hagai " (dries season), when it thins and falls out. The muzzle, inner part of thighs, belly and parts round the eyes are white. Here and there in the Colony, but no often, grey specimens spotted with white are to be seen. Those of brow colour, of the same type as our European ones, do not differ from the grey in the other outward characteristics.

" Their height is about 97 cm., the oblique length of the trunk fro 107 to 110 cm., the chest circumference from 113 to 115 cm.; the head i heavy, the face convex ; the ears are shorter than in the European type, an the mane is short.

" I consider that these animals surpass in sobriety our European types which are proverbial. During the " hagai " they may be seen grazin around the villages on the scanty and short dry grass, which they crop clos in a marvellous way, and which would be quite insufficient food for suc thrifty beasts if they could not supplement it with " ari ".

" The *Kassala* breed resembles the wild Nubian type just as the Abys sinian breed resembles the wild Somali. The Kassala is reddish-grey, mor or less bright and more or less light, which shades off to white on the belly

the inner part of the thighs and the fore legs, the muzzle, and the parts round the eyes ; the back stripe is black, in the form of a cross ; seldom zebra striped on the legs. The type is clearly long-bodied. The height is about 112 cm., the length of the trunk 116 cm. and chest circumference 125 cm.

" The *Etbai* differs from the Kassala breed in its lower stature (100-102 cm.), its diametral shape more similar to that of the Abyssinian breed, from which it is chiefly distinguished by its reddish grey colour and by its shorter and finer hair. White-spotted specimens are found also among the Etbais, but they are rare ".

Somalidand. — The *Somali* donkey, with its two forms, one large and lithe, the other small but not thick set, is a variety of the Abyssinian breed. It is found all over Italian Somaliland, especially between the coast and the rivers.

PROVENZALE describes it thus: —" Its chief points are: — Average height 1.14 m. in large animals, and 1.08 m. in small ; length 1.20 m. in the former and 1.16 in the latter ; average chest diameter 1.28 m. in large and 1.24 m. in small animals. Head heavy, with slightly convex outline ; ears not very long, often cut ; neck massive ; mane short ; barrel long ; members extraordinarily robust, especially the legs... ; coat bright grey during the rainy season and almost reddish, as if tanned, during the dry season. Some specimens occasionally have dark hair with a tendency to brown. Often the colour is paler round the eyes and lips, on the belly and inner part of the thighs. The dorsal line and cross are seldom absent, while zebra-markings, very apparent when they are present, are less common. It is mostly on the coast that specimens are found with light-coloured coats ; this type may easily be descended from the classic Egyptian ass, imported from the opposite Arab shore where it is much used as a saddle animal, especially at Aden.

" The small Somali donkey is a very thrifty animal,which can make the most of the slightest traces of vegetation, so that it is scarcely ever seen in a thin condition during good seasons it is fat and rounded. These small animals carry loads that would seem unbelievable: from 50 to 80 kg., for long and repeated journeys ; but they go at a lazy gait when loaded. The Somalis scarcely ever use them as saddle animals...".

This animal seems to have a fair degree of resistance to trypanosomiasis and might very advantageously be used in Somaliland for breeding mules, or better still jennets.

MULES AND HINNIES

ITALY. — Coming originally to Italy from Greece, the mule at the present time plays a very important part in this country.

In number of mules (496 743 in 1918), Italy comes second to Spain among all European countries. She uses the mule to a large extent as a beast of burden, for draught purposes and for agricultural work. If mule breeding there has developed so greatly without special help, it is because it is more

suitable economically and is of greater practical value, as compared with horse breeding, for local conditions.

Of all the parts of Italy, the richest in mules is Sicily, followed in numerical importance by the southern Adriatic district, the southern Mediterranean district, Piedmont, Latium, Lombardy, Tuscany, Liguria, Venetia, Emilia, the Marches, Umbria, and lastly Sardinia. The real mule breeding, however, is carried on only in Sicily, the Marches, Umbria, the province of Aquila, in Apulia and Calabria ; elsewhere it is carried on to a very limited extent and only mules bought in the breeding centres or abroad when young or already full grown are reared.

Breeding of hinnies (progeny from crossing a stallion with a female ass) is seldom practised, and is to be found in Apulia, Sicily and some other places, but to such a small extent that it is confounded with mule breeding.

Piedmont and Liguria. — The mule population of these two regions is largely of Savoy and Poitou origin, but whereas in Liguria (18 692 head) hybrids are purchased when ready for service, in Piedmont mules of 6 to 10 months old are imported on a large scale and then reared and broken in.

In Piedmont (18 447 head), breeding is seldom if ever carried on, whereas it ought to be encouraged there more than anywhere. The western part especially, on account of its geographical position and its climate, is very well adapted to this kind of breeding. NAPOLEON I saw that this part of Italy fulfilled all the necessary conditions for the purpose, and, in fact, at the beginning of the 19th century, some donkeys were reared as stallions at the " Venaria Reale " near Turin.

The stud book of the imperial breed of horses of the " Mandria di Venaria Reale " (a register which runs from 1806 to 1814) states that there were reared in this district, along with 50 stallion horses, 7 stallion donkeys foaled between 1802 and 1809; these were named *Balotino, Bergamino, Fogoso, Rodomonte, Speranza, Vittorioso and Midas.* They were used as sires till 1814, in which year, after the Russian disaster, all of them except *Speranza* were sent to France, according to the statement written at the foot of the pages containing the pedigree of each stallion : " Je soussigné, inspecteur du haras, certifie que, par ordre de M. le Préfet, en date du 1er mai 1814, j'ai emmené en France le baudet ci-dessus signalé ".

Lombardy. — Almost all the mules reared in this part (10 551 head) are imported from other provinces of Italy or from abroad (especially France and Switzerland). In Lower Lombardy, mules are not bred at all; it is only in the mountainous part, especially the provinces of Sondrio and Bergamo, that there are any production centres, but breeding is always done on a very limited scale, and with the poorest grade of mares, so that the mules raised there are small and thick set.

On the other hand, the Brescian type is of greater height, and in build resembles the Poitevin ; it is found mostly in the Orzinuovi district and is obtained by crossing with the Pantelleria donkey.

" It has for long been known that many Lombardy mares may be *a priori* adapted to mule breeding, but the main want is the lack of a good

breed of donkey. This is the reason for preference being given to horse rearing and the few people who find it necessary to keep mules import them from Switzerland or from other parts of Italy " (Tucci).

Venetia. — Mule breeding is generally of negligible importance there (6 181 head). Only in the provinces of Vicenza, Paduva (Camposampiero, Este, Cittadella, Montagnana) and Treviso (Oderzo) is there in operation any great number of breeding stations for asses, with stallions imported from Romagna, the province of Brescia and even from Pantelleria.

There are in Venetia 2 varieties of mules, differing only in size : — one very small, at most 1.20 metres high, and the other bigger, well made and very strong (Tucci).

Emilia. — There is practically no rearing in the provinces of Bologna and Ferrara or in Romagna, and the few mules found there are imported from other parts of Italy. On the other hand the mule industry is of greater value in the Apennine district of Emilia, especially in the Bardi, Castel San Giovanni, Fiorenzuola, Borgotaro, Finale and Mirandola territories. The mules breed there from native donkeys (with defects) from Romagna, the Marches or Umbria, are not of great size, but to good shape they add strength and endurance in work. In 1918, the number of mules in Emilia was 5 267.

The Marches and Umbria. — The mules of the Marches and Umbria (7 677 head) have the same outward lines and the same disposition. Of medium height (1.35-1.45 m.) they are well proportioned animals ; the neck is short, the body thick set; the limbs are long, strong, vigorous, with large joints, good tendons and excellent feet ; the coat is nearly always bay. They are excellent beasts of burden and very well suited for heavy and quick draught purposes.

In these parts the mule breeding industry is prosperous and the export of young mules very important.

The stallion donkeys used there as sires are not good types ; most of them lack necessary qualities, and, according to Tucci, asses imported from the province of Lecce would help and improve this important branch of animal production, which exists and thrives admirably without assistance because it is based on a first class economic principle, that of profit.

Ancona, Pesaro, Ascoli Piceno, Macerata and Perugia are the provinces that produce most of the mules of the Marches and Umbria.

There are important mule fairs at Loreto (September 23) and Assisi (October 25).

Tuscany. — Mule breeding (6 072 head) here is not widespread, and numerous donkey stud stations exist only in the mountainous parts of the provinces of Pisa, Massa, Arezzo, Siena and Florence. Tuscan mules, which are the result of crossing native mares with native asses of small size and poor development, are not of great size, but are strong and have good staying qualities for work, and are excellent for weight carrying and hauling. The export of these animals every year, chiefly to Liguria and Lombardy, is of some importance.

Latium. — Mule breeding is little practised in this region, where there

where 16 053 animals in 1918. It is difficult here to substitute mules for horses, which still find good buyers and which can be raised here easily and at little cost. Generally the animal shows the influence of the sire, which is very small. Mules of some size are also to be seen, which are active and fatigue-resisting, good trotters, dark bay or black in colour, but they are not very numerous and are the progeny of donkeys of the Marches or of the south, crossed with Roman mares.

South Adriatic Region (Chieti, Aquila, Bari, Lecce, Foggia and Campobasso). — Breeding plays a very important part here (6490 head in 1918), as the sale of the mules is prompt and easy. Campobasso, Lecce and Bari are the provinces where the industry is most widespread, but it is also considerable in the province of Foggia and in the Abruzzi. BERTETTI, quoted by FAELLI, states that the province of Aquila is one of the most important mule-breeding centres. " The real centre for this production lies in the small district of Montereale, not far from Aquila,as hundreds of mules are brought to its fairs and sold when a few months old. They are bought by large owners (" latifondisti ") who carry on the rearing of herds and who use mule transport for all the material required in their business ".

The mule of this part is very high. (from 1.34 to 1.50 m.), thick set, long headed, with long ears and small eyes ; croup wide and not sloping off much ; chest wide and deep ; limbs rather slight but with good joints and strong tendons. The colour is bay, brown or grey. Mules are raised here on open pasture which does not favour the full possible growth, as forage is scarce. In Apulia the hinny is occasionally met with.

South Mediterranean Region (Naples, Avellino, Benevento, Caserta, Salerno, Potenza, Cosenza, Catanzaro, Reggio Calabria). — The provinces of Reggio, Catanzaro, Potenza and Benevento are those which breed most mules; in the rest of this region these animals are generally imported. In 1918 the number of mules in the south Mediterranean region was 36 283.

Calabria supplies the best animals. TUCCI describes them thus : — " Head generally rather big ; forehead wide and square; ears not very long ; eye large and lively ; nose large with well-opened nostrils ; mouth not very narrow ; neck arched and well set on to head, pyramidal in shape and with wide base on the trunk ; barrel cylindrical ; chest wide and deep ; ribs well sprung ; hocks high ; line of back and loins slightly convex ; back thinning off towards withers and widening gradually to the loins ; croup ample and not sloping much ; tail well attached ; abdomen not very bulky ; limbs straight, strong and vigorous, spare but not too slim. These animals can be used for comparatively speedy work and do very well when yoked to light carts. Their coat is dark bay, rarely chestnut coloured, and often black. As grey mules are less desirable, they are much more seldom to be seen. The height varies from 1.50 to 1.60 m. " The mules from this region are in great demand by military remount commissions.

The mules of Basilicata and the province of Benevento, though smaller, greatly resemble the Calabrian animals.

Many hinnies are bred also in the provinces of Cosenza, Caserta, Avellino and Benevento.

Sardinia. — Mule breeding is practically non-existent here (366 in 1918), although the place is quite suitable. It should be remembered that in Sardinia there was, and perhaps still is prevalent, the prejudice that mules spoil the horse. Attempts at crossing, made by the Ministry of Agriculture, which had Pantelleria donkeys sent to this island, so far do not seem to have given the results expected.

Sicily. — This is the part of Italy where mule breeding is engaged in to the greatest extent ; in 1918 it contained 27 799 mules.

" Sicily has never belied the reputation it has gained for possessing a large number of mules of excellent constitution, thanks to the good breed of asses and of mares in the country. These have inherited from their genitors the quantity of blood necessary for making excellent mules which, if they have imperfections in external form inherited from their dams, are nevertheless not to be despised, as it is not elegance and beauty which are expected in the mule but strength and endurance for work. The mule is much sought after in Sicily and the mule industry there grows more and more important; and now, especially when railways are opening up the country, the amount of fast work demanded of the horse, whose pace is more rapid than that of the mule, is falling off, and the latter animal, though less suited for quick going is stronger, more enduring and better able to bear the long fatigue, especially the hard country work, and cannot be replaced by other animals.

" In order to estimate the number and the demand for mules, the condition of our means of communication should be recalled, particularly in the interior of the provinces,whereby animal transport is of more importance than wheel transport. The demand for mules is so great that when there is a shortage of these in the provinces, large numbers are bought from other parts, principally Calabria ". (Demarchi).

The Sicilian mule (Report of the census of the province of Catania, quoted by Demarchi) has a mean height of 1.45 m., with head fine, light, of rectilinear outline, rarely with curves ; ears long ; neck muscular and pyramidal in form ; withers outstanding ; breast wide ; chest round ; back generally straight ; croup often very sloping, sometimes round and arched, but more frequently short and narrow than long and wide ; belly large ; extremities provided with rigid tendons, solid joints and very hard hoofs ; hide generally fine and covered with short bright hair. The coat of the Sicilian mule is generally bay in all its shades, black,grey, but seldom brown. The cross and zebra markings are often found in the lightest coloured coats. White feet occur very rarely.

Some specimens are as much as 1.50 to 1.52 m. in height, but many are under 1.40 m.

Mules are used for work of all sorts : at the plough and as beasts of burden for transport of agricultural products and sometimes of building material. They are used also in light cars, which they draw at the trot ; fairly often they serve as saddle animals, their pace being very convenient as they have an ambling gait (Bizzi, quoted by Demarchi).

Of the 7 provinces in the island, the most important in the mule business are those of Palermo, Girgenti, and Caltanisetta.

There are also many hinnies in Sicily; these are very small but of extraordinary strength and endurance for their size. (CHIARI).

COLONIES. — *Tripoli.* — Mule breeding here is of slight extent and in the interior almost unknown. " To all questions asked by us on the subject, the answer was that only some few specimens could be recalled, and these were obtained more by chance than by design. The breeding of mules from imported asses could give, as in Eritrea, excellent results, but the small number of mares at present in Tripoli would allow only very limited growth in this line ". (PUCCI & GUGNONI).

Erithrea. — The mule of Erithrea and of the whole of Abyssinia stands 1.20 to 1.40 m. high. Docile and very resistant to work and to climatic changes, it is excellent for the saddle. The head is not very light, but is short and somewhat pyramidal; forehead broad and flat; ears not very long: eye large and very spirited; nostrils large; neck arched, with a mane; back straight; loins short and solid; croup well made; breast wide, chest full; legs rather slim, dry, with strong joints; feet very solid, not requiring shoeing; colour varied.

From the reserarches of MARCHI it appears that hinnies are not to be found either in Erithrea or beyond the Mareb.

Somaliland. — North Somaliland produces no mules, and in the southern part these animals come from the Ethiopian plateau through Lugh or Eritrea.

" Attempts at mule breeding would be worth while on the Benadir coast. While under no illusion as to the success of the enterprise, for mule raising is not always an easy matter, it would be advisable to make the attempt, in view of the importance of rearing for service animals, the importation of which from Abyssinia is becoming ever more difficult and expensive. The attempt should be made by using the best stallion asses of the country and the mares of the neighbouring plateau, or better still of North Somaliland and Agaden. The progeny would evidently be of small size but would possess vigour and endurance. (PROVENZALE).

SECOND PART

ABSTRACTS

AGRICULTURAL INTELLIGENCE

GENERAL INFORMATION

157 – **The Nutritive Value of the Wheat Kernel and its Milling Products.** — OSBORNE, T. B., and MENDEL, L. B. with the cooperation of FERRY, E. L. and WAKEMAN, A. J., in *The Journal of Biological Chemistry*, Vol. XXXVII, No. 4, pp. 557-601, 14 diagr. Baltimore, April, 1919. RURAL HYGIENE

The authors undertook a detailed study of the composition and nutritive value of the wheat seed and its milling products, from the particular point of view of the problems arising from modern milling methods and the yield desired of the latter for general use. They review the literature on the composition of the embryo, the outer seed coats or bran, the endosperm and the whole seed, and they give the data extracted from this literature or obtained from their own investigations. The chief points are summarised in the appended tables.

TABLE I. — *Proportion of nitrogen in the various parts of the wheat kernel.*

	Part as per cent. of seed	Per cent. of seed as nitrogen in part	Per cent. of seed as protein in part (N × 5.7)	Per cent. of protein in part	Per cent. of total protein of seed in part
Endosperm	83.5 %	1.61 %	9.17 %	11.1 %	73.3 %
Bran	15.0	0.49	2.80	18.7	22.3
Embryo	1.5	0.10	0.57	36.7	4.4
	100.0	**2.20**	**12.54**	—	**100.0**

[Abstract No. 157]

TABLE II. — *Percentage composition of dry matter in the wheat kernel.*

	Whole wheat	Endosperm	Bran	Embryo
Saccharose	0.61 %	0.24 %	1.92 %	24.34 %
Dextrin, etc.	2.01	3.63	5.03	
Starch	63.80	77.52	0.00	0.00
Pentosans, etc.	6.27	1.80	32.77	?
Crude protein (N × 6.25)	11.25	11.17	17.60	40.25
Fibre	1.75	0.34	11.18	1.71
Fat	2.18	1.15	8.26	13.51
Ash	2.03	0.43	8.61	4.82
Undetermined	10.10	3.72	14.63	15.37

TABLE III. — *Percentage composition of commercial wheat germ meal.*

Sugars	7.71 %
Dextrin	7.50
Starch	18.21
Pentosans, etc.	8.29
Protein (N × 6.25)	31.00
Fibre	2.35
Fat	10.44
Ash	4.91
Undetermined	9.59

For the most part, the experimental work of the authors consisted in a long series of experiments on rats, to reach a quantitative comparison between the entire wheat kernel and its milling products with respect to the nutritive value of their proteins and their content of water-soluble vitamine, both for the maintenance of adult rats and the growth of young ones. The results of these investigations may be summarised as follows :—

The proteins of the wheat kernel are not greatly inferior, for maintenance to casein or even to the total proteins of milk, but are somewhat superior to gliadin. They are adequate for promoting the growth of rats to normal adult size, but the quantity of protein required for growth is relatively large. The crude protein of commercial wheat embryo flour appears to be more efficient than that of the entire wheat kernel for maintenance, and much more efficient for growth. The crude protein of wheat embryo has a higher value for growing animals than that of the embryo, and is as efficient as that of the combination of wheat flour with egg, milk or meat. Hence the agriculturist is justified in his high estimate of the value of wheat bran as a protein concentrate.

The protein of the endosperm was adequate for the maintenance of adults but not for growth, even when the intake was large. A diet containing only 10.3 % of protein furnished by flour supplemented with egg, milk or meat

produced more rapid growth than a diet containing even 50 % more protein derived entirely from the wheat flour. This shows that, under ordinary human dietary conditions, the proteins of wheat are advantageously employed.

Commercial wheat embryo is much richer in water-soluble vitamine than commercial bran and flour. The pure embryo, carefully separated from all the other parts of the seed and used as the sole source of vitamine suffices to maintain young rats but fails to promote their growth. Wheat kernels from which the embryo has been carefully removed are still rich in water-soluble vitamine. Following on these observations the authors raise the question of whether the water-soluble vitamine is a single substance or a mixture of two or more. If it is a single substance il must be a constituent of the endosperm.

Rats fed for 1 year from the time of weaning on diets containing 92% of wheat or 50% of commercial wheat embryo reached full maturity without giving any evidence that wheat contains a toxic substance.

Applying these results to the question of the degree to which it is desirable to mill flour, the authors conclude that, except in special cases, little can be gained by including bran and embryo in the flour when this is used for human food under the conditions prevailing in the United States, where the greater part of the flour consumed is taken along with other foods which make good the nutritive deficiencies of its protein better than would be done by the proteins of embryo and of bran. Again, considering that the rations of farm animals require protein supplements and that wheat bran is a good source, the by-products of milling will be better utilised as food for animals than for man. Besides, as about 80 % of the wheat kernel can be so improved in nutritive value by adding animal products to the diet that a much smaller amount of flour will satisfy the protein need of nutrition, it may well be that the use of the by-products of milling for the production of meat, milk, or eggs will result in a greater economy in the use of flour than if these were used directly for human food.

159 – **Agricultural and Industrial Consultative Committeës in French West Africa.** — *L'Afrique Française, Bulletin du Comité de l'Afrique Française et du Comité du Maroc*, Year XXIX, Nos. 11-12, pp. 341-342. Paris, Nov. & Dec., 1919. AGRICULTURAL INSTITUTIONS

A decree of May 21, 1919, instituted in the chief town of each of the colonies of Senegal, Upper Senegal and Niger, Upper Volta, French Guinea, the Ivory Coast and Dahomey a consultative committee for agriculture and industry, to represent at the local government the interests of the farmers, breeders. forest and industrial lists resident in the colony.

Since the beginning of the world war, French West Africa has managed to intensify its production considerably. In order to keep up and increase this effort the Governor of the colony created this organisation for bringing together the scattered authorities and coordinating their efforts.

The consultative councils in question are composed of two sections : the first of members elected on the ballot list system by the French colonists, and the second of native farmers nominated by the local authority. Their functions are exclusively consultative.

EXHIBITIONS AND TRIALS CONGRESSES

161 – **International Cold Storage Conference at Paris, December, 1919.** — *Communication from the International Institute of Cold Storage*, 9, Avenue Carnot, Paris, 17.

The International Cold-Storage Conference which met in Paris in December 1919 was held for the purpose of considering the creation of an international organisation which would enable every country to benefit in common from the work done by the scientists, economists and manufacturers of every nation, engaged in studying questions relating to cold-storage.

The exploration of the domain of low temperatures has been very productive in results of incalculable value for the whole of humanity during the last thirty years.

Thus, the cold storage of perishable foodstuffs now at the end of the war is the only means of saving from famine not only the French people but also most of the nations of Europe, as it has enabled them to have supplies of meat from the abundant livestock of such distant countries as South America, Australia, Canada, Madagascar, etc.

Furthermore, the exploitation of the inexhaustible resources of oxygen and nitrogen in the air has been undertaken for the first time by George Claude. After giving rise to the industries connected with liquid air, the exploitation of temperatures of — 200° C will be capable in the near future, through the manufacture of artificial nitrates, of creating great sources of hitherto unsuspected wealth which will be available for the common good of humanity.

The Conference held its sittings on December 15, 16, and 17, 1919, in the Ministry of Commerce building. The general meetings took place under the presidency of M. Noulens, Minister of Agriculture and Food, and the Commissions under the presidency of M. A. A. Bernhoft, Minister for Denmark at Paris, assisted by M. T. de Alvear, Minister of the Argentine Republic, M. Minozzi, Italian delegate, for the general administration Commission, and under the presidency of M. Ch. Ed. Guillaume (Switzerland), Director of the International Weights and Measures Bureau, for the second Commission which had special charge of the study of technical questions. Forty Governments, Dominions and Colonies were represented at this Conference by 89 delegates.

The Conference drew up an international Convention text which is to be submitted for ratification to all the Governments interested and which creates an International Cold Storage. Institute, with its seat in Paris, in which all countries invited to enter the League of Nations under the conditions laid down by the Treaty of Versailles will take part. In view of the considerable interest taken, under present circumstances, in a rapid development of all applications of cold to the preservation of perishable food-

stuffs, the Conference immediately set up a general temporary Conference for the purpose of controlling and directing the new Institute. The latter has elected a provisional Executive Committee to secure its proper working, having as President M. André LEBON, late Minister, President of the French Cold Storage. Association; Vice-Presidents M. T. DE ALVEAR (Argentina) Plenipotentiary Minister and Envoy Extraordinary for the Argentine Republic; M. H. A. BERNHOFT, Plenipotentiary Minister of Denmark in Paris; M. KAMERLINGH ONNES (Netherlands), Professor at the University of Leyden; M. MENOZZI (Italy), Director of the Royal Higher School of Agriculture, Milan; M. VESNITCH, Minister of the Kingdom of Servia.

The Executive Committe includes in addition 12 administrators, of various nationalities, and the Presidents of the various international commissions. The Presidents of the following international commissions were nominated immediately, so that they may begin their work as quickly as possible:

1st Commission: Scientific questions.

Section A: Physics, Chemistry, thermometry of low temperatures. President Prof. KAMERLINGH ONNES (Netherlands).

Section B: Units. President M. Ch. Ed. GUILLAUME (Switzerland).

Section C: Biology, Hygiene and Medicine. President, M. D'ARSONVAL (France).

2nd Commission: Cold Storage materials.

Section A: Cold Storage machines. President, M. Louis BLOCK (United States).

Section C: Methods of testing cold storage materials and plants. President, M. BARRIER (France).

3rd Commission: General applications of cold.

Section A: Perishable food and foodstuffs. President, Mr. J. A. RUDDUCK (Canada).

Section B: Agricultural industries. President, M. MENOZZI (Italy).

Section C: Ice industries. President, Mr. D. A. BROWN (United States).

Section E: Liquid air industries. President M. G. CLAUDE (France).

4th Commission: Cold-storage trasport.

Section A: Overland. President, M. CATTANES (Italy).

Section B: Oversea. President Mr. MILTON (Great Britain).

6th Commission: Teaching and diffusion of knowledge. President, Mr. WEMYSS ANDERSON (Great Britain).

7th Commission: General economy and statistics. President, M. RAFFALOVITCH (Russia).

Since its first session the Executive Commission has elected to the post of Director of the new institution M. Emile GOUAULT, Secretary General of the French Cold Storage Association, late Naval Officer.

From the month of January, 1920, the Institute has arranged for the publication of a *Monthly Bulletin of Information on Cold Storage* issued in 2 languages, English and French, in which all the scientific, technical and economic documents of the whole world which have come to the

knowledge of the Institute are classified methodically. This publication aims at bringing quickly within easy reach of scientists and manufacturers, knowledge of the progress made in all parts of the world.

CROPS AND CULTIVATION

AGRICULTURAL METEOROLOGY

162 – **Organisation of the Agricultural Service of Applied Meteorology in Italy** (1) — Azzi, G., in *Bollettino della Unione delle Cattedre ambulanti di Agricoltura Italiane* Year I, No. 2, pp. 1-12. Rome, 1919.

Under the auspices of the Italian Farmers' Society, the author organised a network of agricultural stations of applied geography and meteorology which, since the sowing period in 1918, have begun a series of parallel observations on the growth of wheat and the incidence of meteorological factors.

The observations are recorded on 4 forms : —

1st *form* : from sowing till brairding.

2nd *form* : from brairding till restarting growth in spring.

3rd *form* : from restarting growth till flowering and setting.

4th *form* : from flowering and setting till maturation and harvest.

Each form consists of 2 parts or tables : Series A and Series B. In the table in Series A are recorded both the biological and the meteorological observations made by the observer objectively, without the use of instruments ; while in Series B observations made by means of instruments on temperature, precipitation and sky are set down.

As an example, the 4th. form may be taken, which is as follows : —

Series A. (observations without instruments): —

1) Name of station . . . . . .

2) Name of variety of wheat . . . . . .

3) General condition of seedings at beginning of observations. . . .

4) State how and under what climatic conditions setting took place

5) Milk stage of ripeness (grain completely developed but still green and soft) — Date . . . . . .

6) Wax stage of ripeness (grain yellow and of the consistency of wax) — Date . . . . . .

7) Complete ripeness — Date . . . . . .

8) Before harvesting, choose an area of 1 sq. metre in the middle of the field, cut all the plants on it and count : —

a) the total number of plants

b) the number of plants having 1-2 stems

(1) In a previons work, the author showed the general lines of the fundamental ideas of his system, illustrating his article with complete detailed schedules and forms. The present paper gives a summary of the work done in Italy and reproduces one of the forms (the 4th) used in the agricultural meteorological stations.

The forms have had to be made as simple as possible, in order to encourage, at the beginning, the support and collaboration of the farmers, These helpers in time will improve and thus be able to extend their researches, as provided for in the general programme and in the complete form in the previous publication. (*Ed.*)

c) the number of plants having 1-4 stems
d) the number of plants having 4-5 stems
e) the number of plants having over 5 stems

9) When did harvesting begin and under what conditions was it carried out?

10) Climatic conditions and meteorological phenomena which, in the observer's opinion, favoured the growth and regular ripening of the grain .

11) Climatic conditions and meterological phenomena which, in the observer's opinion, damaged the growth and ripening of the grain . . . .

12) Diseases and insect pests . . . . . .

13) Growth of weeds and damage done . . . . . .

14) Average yield in kg. per hectare: straw . . grain. . . . .

15) Weight of 1 000 grains . . . . . .

16) Weight of 1 litre of grain . . . . . .

17) Other observations considered by the observer as useful to include.

Series B. (observations taken with instruments) : —

Date	Temperature in degrees C.			Rainfall in mm.	Clouds	Other observations (fogs, frosts, storms, etc.)
	Mean	Maximum	Minimum			

The elaboration of data collected after a sufficiently long period of observations will serve : — 1) to determine the crtitical periods ; 2) to determine the phenological means (for drawing up phenoscopic charts); 3) to determine for each decade of the growing period the mean frequency of the various meteorological phenomena ; 4) to determine the amount of damage due to each of the unfavourable meteorological phenomena.

The knowledge of the 4 above-mentioned data will allow of striking an exact bio-meteorological balance, by means of which it will be possible : —

1) to select from the different varieties of wheat the one best suited to a given district ;

2) to fix the best date for sowing and other operations so as to make the critical periods coincide with the most favourable times possible as regards the weather ;

3) to help the selector in his work of trying to combine in the best proportions the two qualities "specific productiveness,, and "resistance to the most harmful meteorological phenomenon,,.

In addition to the forms, a table of The Agricultural-Geographical Census for Wheat has been sent out to the stations, in which there are indicated

all the vareities of wheat grown in a given zone. For each variety the following information is supplied: —

1) Approximate area % of total area sown with wheat.

2) Average yield of grain per hectare on land of average fertility.

3) Morphological characteristics (if the wheat is awned or not, coloured or not).

4) Physiological qualities (early or late, etc.).

5) Land best suited for wheat-growing.

6) Land not suited for wheat-growing.

7) Adverse metorological phenomena to which the variety in question shows itself specially resistant.

8) Adverse meteorological phenomena from which the variety in question shows itself particularly liable to damage.

To this special information are added other general data regarding topographical and agro-geological conditions and the meteorological phenomenon or phenomena most injurious to wheat in the district concerned.

On the basis of the census data on wheat at several stations, a beginning will be made, during 1920, with a series of genealogical selections with the aim of isolating, from amongst local varieties, the pure lines which best adapt themselves to the climatic conditions of the place by uniting in the best proportions the two qualities of specific productiveness and resistance to the most unfavourable climatic factor, and hence giving the maximum yield of grain.

In the general work programme prepared in full detail for the 1st decennial period and the following one, an ever-extending collaboration with Breeding and Selection Institutions is provided for, so as to ensure that the results which will gradually be obtained may have the widest and most rational application.

163 – **The Climate of Illinois From an Agricultural Point of View.** — Mosier, J. G. in *University of Illinois Agricultural Experiment Station Bulletin* No. 208, pp. 1-125 + 14 fig. Urbana Illinois, Apr. 1918.,

Thetwo absolutely predominating factors for the growth of crops in the State of Illinois : are precipitation and temperature (and frosts)

Rainfall. — The total rainfall would be sufficient each year to produce maximum crops if the distribution was regular.

Distribution of rainfall. — The annual average for the State of Illinois is 37.98 inches, or more than 3 inches per month, an amount more than sufficient to insure an abundant harvest ; the fault is in the distribution of the rain : during the 10 years 1906-1915, at the University of Illinois, there have been 25 periods of 20 days or longer in each of which the rainfall has been less than 1 inch ; 6 of these periods lasted 20 days or longer. If the deficit periods coincide with one of the periods in which the atmospheric factor " moisture " is critical for the crops, the harvest is always much reduced. Hence the necessity for taking every precaution to preserve the moisture in the soil by preventing evaporation and dispersion. Maize, during the 3 months of its growth, requires at least 7.5 inches of rain. In-

ther words, the summer rainfall in June to August is the most important or maize.

The following data show the quantity of rainfall during the said eriod and the yield of grain (maize) : —

Summer rainfall	Bushels of maize per acre
ess than 7 inches.	25.3 (8 year average)
etween 7 and 10 inches.	32.4 (9 » »)
lore than 10 inches.	39.8 (11 » »)
lore than 13 inches.	45.9 (7 » »)

There is, therefore, a difference in yield of 20.6 bushels corresponding o the minimum and maximum rainfall.

TEMPERATURE. — Between the districts of the extreme north and those f the extreme south there is a difference of 11° F. in mean temperature nd a difference of 4 ½ weeks in the duration of the frostless season. Such ifferences cause noticeable effects on the distribution of crops, and while he cotton plant grows in the southern limits of the State, the cultivaion of maize in the northern limitis, though limited to early maturing arieties, is sometimes damaged by destructive early autumn frosts.

In the lower third of Illinois, high temperatures hinder the growth f oats which, on the other hand, constitutes one of the commonest crops n the northern districts.

To insure the normal growth of any crop a certain number of hours re required during which the temperature remains above the minimum or growth. These are " degree-hours ", obtained by multiplying the umber of hours during which the temperature is above the minimum y the difference in degrees between the average temperature during the eriod of growth and the minimum required for growth.

For the various groups of districts into which Illinois has been subdiided we have the following degree-hours calculated according to the aver.ge temperature on May 20 and September 15 and taking 49° F as the inimum temperature for the growth of maize : —

Districts	Degree-hours
Extreme northern	57 910
Central northern	60 860
Central	67 240
Central southern	72 800
Extreme southern.	76 560

From 1876 to 1915 for the State as a whole the average number of legree-hours was for the growing period of maize, 66 708 per year, with a naximum of 75 240 in 1901 and a minimum of 57 930 in 1882. In 1901, the

yield was 21 bushels per acre and in 1882 it was 24 bushels. During the period of 40 years, in 21 years the number of degree-hours was above the average and the yield in grain averaged 30.4 bushels per acre, while in the other 19 years the number of degree-hours was below the average and the average yield 33.6 bushels. The better yields were therefore obtained in the years when the number of degree-hours was slightly below the average.

The following table sums up the data regarding the yield in grain of maize, the number of degree-hours and the rainfall for July-August at the Agricultural Experiment Station of Urbana : —

Degree-hours	Average yield in grain per acre (bushels)	Average rainfall July and August (inches)
Over 70 000	21.0	3 30
Between 70 000 and 65 000	32.6	6.05
Between 65 000 and 60 000	36.5	6.87
Below 60 000	36 6	6 82

These data, while they confirm the existence of correlation between the yield and the number of degree-hours, also indicate that there is a correlation between the latter and the rainfall, from which it may be deduced that lack of rainfall is the real cause preventing the crop from utilising the greater temperature possibilities.

Frost. — The following Table indicates the average date of the last destructive frost in spring and that of the first autumn frost, also the average number of days in the frostless season in the various districts into which Illinois has been divided : —

Districts	Last frost in spring	First frost in autumn	Duration of the frost less season
Extreme northern	May 4	October 12	161 days
Central northern	» 2	» 15	166 »
Central	April 26	» 16	173 »
Central southern	» 15	» 20	188 »
Extreme southern	» 14	» 24	193 »

164 – **The Possibility of Forecasting Summer Temperature and the Approximate Yield of Rice in the North of Japan.** — Okada, E., in *The Bulletin of the Central Meteorological Observatory of Japan*, Vol. III, No. 1, pp. 19-32. 1 pl. Tokio, 1919.

In the north of Japan the climatic factor which decides the yield of rice is the general summer temperature, especially during August. When the air keeps at a high temperature during the latter month and when there are many hours of sunshine, the harvest is on the average a very good one.

A cold month of August is followed by poor crops, as in 1902, 1905, and 1913, when a terrible shortage prevailed in the north of Japan.

If it were possible to have a very early forecast of the August temperature, the information might be of use in connection with the harvest.

Some men of science talk of a close relation between hydrographic and meteorological phenomena on the eastern coast of north Japan, and they propose undertaking a series of systematic observations on sea temperatures for the purpose of deducing therefrom some indications as to the kind of summer to follow. Observations of such a nature, however, involve many difficulties.

A close correlation has also been discovered between the summer temperatures in Japan and the number of sun spots, but the problem of forecasting sun spots long in advance is far from being solved. In the absence of better data the author shows in his article the results of an attempt to apply statistical methods to the forecasting of summer temperatures, based on the fact that in the north of Japan temperature variations are related to barometric variations observed in March at the observatories of Zikawei (China) and Miyazaki (south-eastern coast of the island of Kiushiu), and during the period March to May at the observatories of Santiago (Chile) and Buenos Aires (Argentina). The annexed table shows the coefficients of correlation between the pressures in South America (March-May) and the August temperatures at 8 Japanese stations, in the course of 30 years' observations (1884-1913).

	Stations	Corrected coefficient	Probable error
Hokkaido. . .	Nemuro	0.496	0.093
	Sapporo	0.629	0.074
	Hakodate	0.571	0.083
Tôhoku. . . .	Aomori	0.536	0.088
	Miyako	0.462	0.097
	Isinomaki	0.627	0.075
	Akita	0.476	0.095
	Niigata	0.538	0.087

Hence there exists a positive and strong correlation. The higher the barometric pressure in March-May at Santiago and Buenos Aires in relation to the pressure of the preceding year, the higher the August temperature will be in north Japan in comparison with the temperature of the preceding year.

Between the barometric gradient Zikawei-Miyazaki (1) and the August temperature at Japanese stations there are the following correlation coefficients: Nemuro 0.341, Sapporo 0.402, Hakodate 0.402, Aomorio. 378 Myako 0.312, Isinomaki 0.465, Akita 0.391, and Nijgata 0.424., Here also the parallelism between the two groups of values, barometric and thermic, is very evident: the greater the difference in barometric values between Zikawei and Miyazaki, the higher will the August temperature be in north Japan.

(1) The difference between the pressure at Zikawei and that at Miyazaki. (*Ed.*)

Given on one hand, the close relationship between the August temperatures and the rice yield and, on the other hand, the high degree of correlation between the August temperatures in Japan and the barometrice values in March in South America and in March-May in China and south Japan (island of Kiushiu), it should thence be possible to estimate fairly roughly, from the end of spring, what the rice yield will be, after establishing the connection between the thermic values in August and the grain yield.

A moment's reflection will suffice to show how much more simple and natural it is to calculate directly the correlation coefficient between the yield of rice grain in north Japan and the barometric values at the above-mentioned stations.

In his calculations the author deals separately with the crop for the Hokkaido district (the Nemuro, Sapporo and Hakodate stations) and for the Tohoku district (Aomori, Miyako, Isinomaki, Akita and Niigata).

Hokkaido: the coefficient of correlation between the rice yield and the annual variation of barometric pressure in South America for the month of March is equal to 0.674. If, instead of South America, the barometric gradient of Zikawei-Miyazaki (for March) is taken, the coefficient is equal to 0.581.

Tôhoku : the values of the coefficient of correlation are 0.459 and 0.431 respectively.

Hence the coefficients in both cases are very high. It may be concluded from this fact that in north Japan a poor rice crop in most instances is preceded by a very low barometric pressure over South America in the period March-May and by a very slight Zikawei-Miyazaki gradient (March).

165 – **Climate and Cotton Growing in the United States.** — Stine, O. C. and Baker, O. E., in *Monthly Weather Review*, Vol. XLVII, No. 7, pp. 487-489, 12 figs. Washington, July 1919.

Climate of the cotton belt. — In this belt the variations in yield per acre and the density of the cotton acreage depend principally on soil conditions. On the other hand the outer boundaries of cotton production, both to south and north, are determined almost entirely by climatic factors. The cotton belt has an average summer temperature of 77°F. along the northern boundary. In eastern Kentucky very little cotton is grown for household use in the mountains, although the summer temperature is only 74° F. In the southern portion of the cotton belt the summer temperature is 80° to 85° F., and in the Imperial Valley of California it averages 95° F.

Along the northern margin of the belt the last killing frost occurs, on the average, about April 10,and the first killing frost in autumn about October 25, so that the frostless season is about 200 days. In the southern portion of the belt the last killing frost in spring occurs about March 10, on the aveage and the first killing frost in autumn about November 25, the frostless season being 260 days or more in length.

The average annual precipitation in the Cotton Belt ranges from 23 inches in western Oklahoma and Texas to 55 inches in eastern North Caro-

lina and 60 inches in southern Mississippi, and it is always heavier in the Mississippi Valley States than in Texas or the South Atlantic States.

The summer rainfall is somewhat greater than that of the other seasons, especially in the southern and eastern portion of the belt, reaching a maximum of 30 inches in southern Mississippi and in eastern North and South Carolina, while in the Black Prairie of Texas the amount averages only 8 inches.

Autumn is the driest season of the year, practically all the important cotton regions receiving less than 10 inches of rain during the autumn months.

Weather conditions favourable for cotton : a mild spring with light but frequent showers ; a moderately moist summer, warm both day and night ; a dry, cool and prolonged autumn. Too cool weather in the spring retards growth, and too much rain may induce the seed to rot rather than to germinate or later cause the development of surface roots, to the sacrifice of the deeper roots, resulting in wilting and shedding of leaves and bolls during drought.

May and June particularly are critical months, when heavy rainfall, especially if accompanied by low temperatres, is very detrimental.

Drought in the spring often kills the young shallow-rooted seedlings.

A wet summer promotes vegetative growth at the expense of boll production, while drought stunts the plants, causes early maturity and reduces the yield.

The most unfavourable conditions for the crop are a cool and wet May and June, followed by a hot and dry July and August.

The ideal rainfall is of the thundershower type with several days of bright, warm weather between rains. Plenty of sunshine is especially important in June and early July when the plants are in bloom.

When the cotton matures and the bolls begin to open in the latter part of August, rainy weather is undesirable, as it retards maturity, interferes with picking, and discolours or damages the exposed fibre. Moderate rain in early September, however, favours the production of a large top crop of late maturing bolls. The greater daily rage in temperature in a dry autumn is also favourable to the maturing crop as it checks vegetative growth and induces fruiting. Early frost in autumn kills the top crop on the upper branches of the plant or causes the bolls to open prematurely, often seriously reducing the yield.

Dates of planting and picking. — Cotton planting generally begins in the southern portion of the cotton belt about March 20, and progresses northward ; in the central portion planting begins during the first week in April, and in the northern portion about April 20. It lasts usually 2 to 3 weeks.

In extreme southern Texas chopping out begins in April, in the southern districts in May, and in the northern districts between June 20 and July 5.

Cotton picking begins about August 10 in the south, in the last weeks of August in the centre and only about September 10 in the northern portion of the belt.

166 – **The Influence of Pruning on the Resistance of Fruit Trees to Cold: Investigations in the United States.** — WHITTEN, J. C., in *Monthly Weather Review*, Vol. XLVII, No 8, p. 570. Washington, August, 1919.

The general condition of a plant at a given time, the degree of maturity or quiescence, the quickness of growth, have all a more or less marked influence on the plant's resistance to unfavourable surroundings.

Investigations made at the Missouri Agricultural Station have shown that sap concentration is least (minimum sugar content) during the periods of rapid growth in spring and at the beginning of summer.

The supension or slowing of growth brings about an ever-increasing concentration of sap, with a rise in reserve stores.

The earlier that growth stops in autumn, the greater will the concentration of sap be and the greater will the quantity of reserve material be.

On the other hand, as the degree of concentration increases, the freezing point becomes lower and thus the plant is able to stand lower temperatures than would be the case if the juices were weaker.

For example, in a peach orchard, vigorous growth of branches continued up to the first autumn frosts. The following spring the blooms were killed in a single night by a fall of temperature to — 2.78° C.

In another orchard in the same district, growth stopped much earlier, while the leaves kept healthy and active until the first frosts.

The following spring the flowering buds were very resistant to frost.

PRUNING. — With the old pruning methods, trees underwent every winter a very severe pruning which brought about a vigorous growth of shoots at the ends of the pruned branches. These shoots continued lengthening and producing leaves all summer, thus preventing the concentration of sap and the storage of reserve material.

With the new pruning system, on the other hand, the main branches are untouched; they are only cleared every year by the removal of useless side branches, so that growth stops early.

These branches and their leaves, of slow growth, have compact tissues, evaporate and transpire very little and thus keep their sap concentrated. In addition, the leaves do not remove moisture from the fruit during dry seasons.

By this pruning system not only is resistance to low temperatures obtained, but also resistance to drought.

167 – **A New Acid and Alkaline Scale especially for Soils.** — WHERRY, E. T., in *Journal of the Washington Academy of Science*, Vol. IX, No. 11, pp. 305-309. Washington, 1919.

The author proposes a new scale for acid and alkaline reactions, introducing the idea of *specific acidity* and *specific alkalinity*, the unit of which instead of being the gramme-equivalent per litre is the number of gramme-equivalents of each ion (hydrogen or hydroxyl) present in distilled water at the usual temperature. These values would represent the respective chemical potentials and according to a suggestion of ADAMS are indicated by the letter X, the initial of the Greek word meaning " chemical ".

In this scale the values for the hydrogen ion represented by X_H, are

such that neutrality is shown by $X_H = 0$, and are obtained by subtracting the exponent P_H from the value 7 (1).

The annexed table gives a summary of the values corresponding to the most probable reactions in the soil.

Scale of Soil Reactions.

Generic reaction	Usual method				Proposed new method				Denominations proposed for the specific reactions
	H +	OH −	P_H	P_{OH}	Specific acidity	Specific alkalinity	X_H	X_{OH}	
	10^0	10^{-14}	0	14	10^7	10^{-7}	7	− 7	
	10^{-3}	10^{-11}	3	11	10^4	10^{-4}	4	− 4	superacid
Acid . . .	10^{-4}	10^{-10}	4	10	10^3	10^{-3}	3	− 3	mediacid
	10^{-5}	10^{-9}	5	9	10^2	10^{-2}	2	− 2	subacid
	10^{-6}	10^{-8}	6	8	10^1	10^{-1}	1	− 1	minimacid
Neutral . .	10^{-7}	10^{-7}	7	7	10^0	10^0	0	0	minimalkaline
	10^{-8}	10^{-6}	8	6	10^{-1}	10^1	− 1	1	subalkaline
	10^{-9}	10^{-5}	9	5	10^{-2}	10^2	− 2	2	medialkaline
Alkaline. .	10^{-10}	10^{-4}	10	4	10^{-3}	10^3	− 3	3	superalkaline
	10^{-11}	10^{-3}	11	3	10^{-4}	10^4	− 4	4	

In the relations between acids and plants there may be noted, with regard to reactions thus designated, certain more or less well defined types: peat infra-acquatic, super acid, with a characteristic flora, oxylophyte or acidophil; supra acquatic peat, mediacid, also with a oxylophyte flora; ordinary forest and subacid field soils; limy soils, subalkaline; alkaline lands, medialkaline and superalkaline.

One of the advantages of the proposed scale would be the facility for making comparisons and it may be applied to all determinations hitherto expressed with the SÖRESNEN exponent (P_H).

168 – **Changes in Composition of the Soil and of the Water Extract of the Soil Following Addition of Manure.** — HIBBARD. P. L. (University of California), in *Soil Science*, Vol. VII, No. 4, pp. 259-272. 3 Figs. Bibliogr. of 14 works. Baltimore, 1919.

Fresh manure was mixed with loamy soils in the proportion of 1, 2 and 5 %, the mixtures were kept at optimum moisture point and analysed, during the year, from time to time.

It was found that carbon dioxide in the soil atmosphere was increased in proportion to the manure added, but, in the year's trial, the carbon

(1) See *R.*, Feb., No. 159 (*Ed.*).

decreased, while the nitrogen remained constant. Water-soluble matter at first decreased, as compared with untreated soil, then increased but without ever equalling the sum of that in the soil plus that in the added manure. Nitrate quickly disappeared, and later reappeared and increased in proportion to the manure used.

The above, in short, is a confirmation of the fact that fresh manure should not be added to a soil just previous to or during the time a crop is growing. It should be remembered, however, that these experiments were made with glass jars.

169 – **The Influence of Heated Soils on Seed Germination and Plant Growth.** — Johnson, J. (Department of Horticulture, Wisconsin Agricultural Experiment Station) in *Soil Science*, Vol. VII, No. 1, pp. 1-87, 9 pl., bibliography of 79 publications. Baltimore, 1919.

The method of sterilising soils by the action of heat is more and more appreciated: the phenomena met with in this method of treatment are complex and form the subject of an extensive scientific literature.

Besides the phenomena which have been noted in the soil itself, the author deals with the changes which take place in heated soil; he regards them from the standpoint of their effect on seed germination and on plant growth and he endeavours to draw from them conclusions on the subject as to the probable natures of these changes. It appears from observations made that, generally, when heated to 100°-115° C., all soils retard both seed germination and plant growth, but this retardation is followed by increased vigour of growth; the degree of these actions varies according to the soil, seed, and plants used and the conditions under which the experiments are carried out. In a series of trials made with 7 different soils heated to temperatures varying from 115° to 500° C. and using various seeds and plants, a general and gradual toxic effect was noticed on germination and first stages of the growth of the plants; the toxicity reached its maximum in soil heated to 250° C., then decreased at higher temperatures and became practically nil at 350° C. or above. At any rate, the soils cease to be toxic after a time and do so sooner when the intensity of toxicity is less; on the other hand, the final beneficial action of heating is greater when the toxicity is more intense at the commencement of growth.

The toxic action caused by heating soils and the subsequent beneficial action that results, vary in a marked manner according to the nature of the soils; these differences appear to be correlated with the balance of all the various factors which affect the soil tested.

Seed of different plants also vary in a marked manner in their resistance to the toxic action of heated soils, which depends largely on the family to which they belong: — the Gramineæ and the Cucurbitaceæ are usually resistant, while the Leguminosæ and the Solanaceæ are more sensitive. However, seeds classed as sensitive may show accelerated germination in soils which do not become highly toxic or which have been only slightly heated. Like the seeds, the plants themselves differ much in their sensitiveness to the toxic action of heated soils although there may not always

be parallelism with the influence of toxicity on germination even in the same species.

In certain heated soils the growth of fungi, especially those of the genus *Pyronema* is similar, as regards toxicity to germination and plant growth, to that of higher plant species ; fungi, and apparently, bacteria grow very well in soil previously heated to 250° C., that is to say, in soils most toxic to seeds and plants. The ammonia content and the concentration of the soil solution of a soil heated to various temperatures are highest at about 250° C., and they diminish gradually with an increase or decrease in the temperature of heating; both are correlated with the initial toxic action, caused by heating the soils, on germination and early growth, with the later beneficial action which follows, and with the growth of lower micro-organisms in the soil. This correlation is only true for a given soil and not for all soils. The absorptive capacity of a soil appears to have an influence on its toxicity, for it has been noticed that the toxicity to germination of water extracts of various heated soils is more directly proportional to the ammonia content. The author considers that the toxic action in heated soils is mainly due to the ammonia produced during the heating from ammonium carbonate which, in normal conditions, would be gradually decomposed ; as a matter of fact the addition of ammonia in varying amounts to a soil produces effects on germination and plant growth in many respects similar to those caused by heating. Similar effects of high toxicity on the germination of certain seeds can be obtained with heated soils or their extracts and equally with certain strengths of ammonia, and these effects cannot be reproduced except with ammonia or ammoniacal salts.

At any rate, the toxic substance produced by heating the soil is recovered or transformed into non-toxic compounds in soils kept under normal conditions of cultivation, and this is caused by the activity of the ordinary soil flora ; however, this flora may, at least apparently, increase the ammonia present, which, according to the author, is not, however, found in the free state but in the form of transition compounds which are decomposed in the analytic processes.

The temperature at which the soil is kept after heating has great importance so far as the permanence of toxicity and the commencement of beneficial action are concerned, the toxic action being more persistant and destructive below 25° C.

It should be noted that all the above mentioned conclusions apply particularly to soils heated to high temperatures and in a dry state, but the author believes that there are no fundamental differences between soils partly sterilised by steam and soils heated to higher temperatures and reinoculated with normal soil flora.

It should not be overlooked that the destructive action noted, should not diminish the value of sterilising the soil by heating both for research and practical purposes ; it is even a treatment to be recommended (especially steam sterilisation) whenever it is necessary to eliminate certain organisms from the soil ; but in that case a slight retardation in growth must be expected (which will always be followed by benefit) and in these

special cases (relating to both the soil or plants or in certain environments) marked changes in the normal course of growth are to be reckoned with.

170 – **Progress of Irrigation in India, Egypt and the Sudan.** — I. *Statement Exhibiting the Moral and Material Progress and Condition of India during the year* 1917-18, No. CIV, pp. 141-147. London 1919. — II British India, Progress of Irrigation. *The Board of Trade Journal*, Vol. VIII, No. 1192, p. 419. London, 1919. — III. *Report on the Progress of Agriculture in India for* 1917-18, pp. 107-111. Calcutta, 1919. — IV. CUNNINGHAM, B., Irrigation in Egypt and the Sudan. *Nature*. Vol. CIV, No. 2003, p. 67. London, 1919.

I, II, III. *Irrigation in India.* — Two-thirds of the population of India live by agriculture, and one of the most important conditions of the growth of agriculture is the irrigation system. There are four methods by which irrigation is carried out in India. The first is by placing some form of barrage across a river which flows throughout the year and diverting the water by means of a canal to the country to be irrigated. It is on this principle that the great perennial canals of northern India are constructed. The second method is by leading canals direct from rivers without the use of barrages. These canals obtain no water until the river reaches a certain height. They are known as inundation canals, and constitute the majority of the canals in Sind and many of those in the south-west of the Punjab. The third method is by building a dam across a valley and storing the rainfall water during the monsoon, the water so held being distributed to the neighbouring lands by means of canals. The reservoirs thus formed vary in size from the tiny village tank to the monumental works in the western Ghauts, with masonry dams up to 270 ft. in height. The fourth method is by lifting water from wells, either by indigenous and primitive methods such as the leathern bag drawn by bullocks and the Persian wheel, or by means of power-driven pumps.

For financial purposes, Government irrigation works are classified as productive, protective, or minor works. The capital outlay on works of all three classes to the end of the year 1917-18 amounted to about £ 50 000 000 and it is significant that over three-fourths of this amount was expended on productive works. These are works which are expected to pay all charges, including interest, within ten years of completion, and it speaks well for the efficiency of their construction and management that in 1917-18 the receipts, including land revenue due to irrigation, not only met all expenses, including interest, but yielded a net profit of £ 2 000 000. There are now over 66 000 miles of main and branch canals and distributaries, from which an area of nearly 26 000 000 acres is irrigated.

An estimate has been made that the value of the crops irrigated by Government works in a single year exceeds by more than 25 per cent. the total capital outlay on such works. It would be difficult to frame in a single sentence a more striking illustration of the benefits of irrigation in India.

Several new irrigation schemes which have been under investigation are of the first magnitude. There is the Sukkar barrage project in Sind, which provides at an estimated cost of nearly £ 7 500 000 a weir across the Indus, with two large canals taking off from the right and left banks of

the river to supply water for the perennial irrigation of areas now dependent on inundation canals. Another extensive project is that of the Sind-Sagar-Doab canal in the Punjab, which comprises a barrage on the Indus river, with an extensive canal system providing for the irrigation of some 200 000 acres at a cost of nearly £6 000 000. Also in the Punjab, on the Sutlej, is the site of the Bhakra Dam, estimated to cost £7 000 000 and designed to store water to a height of 360 ft. above the river bed. About 1 400 000 acres will be irrigated and the dam, if built as now designed, will be higher than any in existence. In Madras, the Cauvery (Metur) reservoir project contemplates a dam, a canal seventy-eight miles long, and a connected tributary system, costing altogether between £2 000 000 and £3 000 000. It is estimated that over 370 000 acres of land will be brought under irrigation and that provision will be made for the complete control of the present fluctuating supplies of the Cauvery delta system. In Oudh, a canal is proposed which will, if constructed, rank among the largest irrigation works in the world. The net capital outlay is estimated at about £5 750 000 and the gross area commanded by the works will be over 8 000 000 acres though only 2 000 000 acres will be irrigated annually. Larger still is a scheme for irrigating more than 3 000 000 acres in the Sutlej valley.

Altogether there are thirty-four major works either under construction, awaiting sanction or in course of investigation in India. If these works are all undertaken they will extend the benefits of irrigation to an additional area of about 11 000 000 acres a year at an estimated cost of £32 000 000 and should produce a net revenue of nearly £2 5000 000.

The Review of Irrigation in British India during 1917-18, recently published by the Public Works Department of the Government of India, shows that during the year the total area irrigated by all classes of works amounted to nearly 26 000 000 acres. Towards this area, productive works contributed 16 922 000 acres (in the Punjab 7 500 000 acres, Madras Presidency 3 500 000 acres, United Provinces 2 871 000 acres, and Sind 1 364 000 acres). The total capital outlay of the year on productive irrigation works amounted to nearly 57 $^{3}/_{4}$ crores of rupees. The gross revenue reached 701 ½ lakhs of rupees, and working expenses nearly 216 $^{3}/_{8}$ lakhs. The net revenue, at a little over 485 lakhs, represents a return of 8.40 % on the total capital outlay. The total areas irrigated by thirty-six protective works in operation amounted to 497 000 acres. The net revenue was only a little over one lakh, equivalent to 0.10 % on the total outlay. This low return is partly due to expenditure on works under construction which are not yet earning. Many useful and important works of this nature are under construction in Bombay, the United Provinces and the Central Provinces, while in the last-named province seven tank schemes (aggregating over 40 lakhs) are in progress. The area irrigated by minor works was 8 477 000 acres. The total capital outlay was 448 lakhs and the net revenue amounted to Rs.35, 39,000.

Finally, there are at least 3 000 000 wells in India from which water is lifted for irrigation and the number of men and cattle employed on this

work is very large. The question of pumping water from wells, as well from river channels and watercourses, is a very important one to India, subject as it is to extensive and serious failures of the rains. There are large areas of land which border on rivers retaining an ample supply of water throughout the hottest weather and such land can be effectually protected from drought by the installation of pumping machinery. The Indian Irrigation Commission of 1901-03 reported that the area under well inrrigation was not less than 16 000 000 acres.

IV. *Irrigation in Egypt and the Sudan.* — The schemes of Nile irrigation at present in hand include three separate projects relating to different sections of the river. There is a scheme for the development of the Gezirah plain of the Sudan on the Blue Nile, just south of Khartoum ; another for the benefit of Egypt proper by utilising the flood-waters of the White Nile ; and a third scheme of drainage improvement of the deltaic region included in the provinces of Gharbieh and Beheira, lying below Cairo.

The Blue Nile scheme consists of a dam at Makwar, about five miles south of Sennar and 175 miles south of Khartoum, with a canal, some forty miles in length, leading from just above the dam to the district to be irrigated, which is a remarkably level and treeless plain some 300 000 feddans in extent (1 feddan = 1,04 acre). The cotton, which it is capable of producing, will be raised as a winter crop, absorbing the river winter supply without interfering with the summer discharge. The dam will be a work of some magnitude, withstanding, when completed a head of 40 ft. of water, and capable of coping with a discharge of some 1 250 000 gallons per second in a river subject to sudden and extreme fluctuations.

The White Nile scheme is, fundamentally, a development of the Aswan undertaking, which has now reached the limit of its effective utility. In 1916, the demands of the area under cultivation exceeded the available supply. It is, accordingly, proposed to construct an auxiliary reservoir dam at Gebel-el-Auli, or Gebel Aoli, on the White Nile, capable of impounding an adequate summer supply supply of water for Egypt, and at the same time reducing the excessive flood-waters of the main Nile. This scheme has been the subject of certain criticisms by Sir William Willcocks.

A subsidiary work is the formation of a channel from the Blue Nile above Sennar, so that the superfluous water from that reservoir may be conveyed to the Gebel-el-Auli reservoir. The Gebel-el-Auli dam will have a pressure-head of 23 ft.

The increased water supply to Lower Egypt, due to the Aswan reservoir, has severely taxed the drainage channels of the provinces of Gharbieh and Beheira, forming the alluvial plain between Cairo and the sea. It is necessary to find some measure of relief, and a solution of the problem is sought in the construction of large pumping installations on the borders of Lake Mareotis and Lake Borollos.

171 – **Utilising the Waterfalls of the Irian, in Indo-China, for the Industrial and Agricultural Development of the Colony.** — *Ministère des Colonies, Bulletin de l'Agence Générale des Colonies* (formerly *Bulletin de l'Office Colonial*), Year CII, No. 142, p. 591. Paris-Melun, Oct., 1919.

The famous falls of the Irian are destined to furnish great hydraulic power hitherto neglected in Indo-China and are capable of giving new impetus to the industrial and agricultural development of the country.

A valuation of this wealth in " white coal " has been ordered by the Governor General, who has decided to lend his patronage to a company now being formed for its exploitation.

172 – **Irrigation of Olive-trees in Tunis.** — See No. 206 in this *Review*.

173 – **The " Sortume ".** — TARCHETTI, A., and TOURNON, A., in *Il Giornale di Risicoltura* Year IX, No. 8, pp. 113-125. Vercelli, August, 20 1919.

" Sortume " (from *sorgere* = to gush up, break out) is the name given by the farmers of Piedmont and Lombardy to the unfavourable circumstances (peculiar to the irrigated alluvial district and due precisely to the welling up or rise of water from the lower strata to the surface of the soil) which give the land an excess of moisture, and consequently of acidity which is constant and cannot be diminished by means of ordinary cultivation. The " sortume " gives rise to a kind of seeping which makes the soil dark and shiny, and in the worst cases gives it a sort of characteristic irridescent viscosity which makes cultivation, and especially ploughing, exceedingly difficult. Flooding the land does not prevent the formation of the " sortume ", which, when it appears in rice fields, assumes an exceptionally important and serious aspect. This hydraulic phenomenon happens over areas varying from a few ares to several hectares. The usual methods adopted to try and combat it are: — deep ploughing; a close network of drainage trenches; the application of quicklime, heavy green manuring; etc., but all these are merely palliatives and do not affect the causes of the phenomenon.

In places affected by the " sortume " the vegetation, though flourishing at the beginning of the agricultural season, comes to a halt, wilts and sometimes dies off. The fact that plants whose roots require water are also damaged by the " sortume " shows that the wilting is not due to the water which moistens the roots but to the quality of this water. The latter is, in fact, cold and unaerated, so that it cannot support root respiration. The want of oxygen helps the formation of acidity in the soil.

In places where the "sortume " appears, the water rises under pressure from below, the causes of which, varying according to the case, are under investigation by the authors.

In alluvial soils, the " sortume " is often a consequence of communicating chambers, in which case the remedy lies in purely hydraulic measures, namely in cutting the closed seam in which the water circulates.

It not unfrequently happens, however, that the " sortume " appears in regions far from rivers and torrents and keeps on after the ground and

canals round about are dried up, even within a radius of several kilometres. Some writers conclude from this fact that the " sortume " may arise from the inexhaustible underground streams, which are common in alluvial districts. But as the " sortume " appears almost exclusively during the irrigation periods, and as it disappears at the times when the canals are generally dry, this shows that, as a rule, these natural underground streams are not the cause, but small veins very near the surface, fed by the canals or by the surrounding submerged ground. Again, in places where underground streams are abundant the " sortume " phenomena are much more in evidence and form real springs which it is easy to tap and drain off. Usually these points where water rises are to be found at the foot of earth terraces, and in most cases the presence of peat is typical of them.

It must be allowed that the "sortume " wells up under pressure when the zone of earth causing the pressure lies much higher than the zone in which the " sortume " takes place, but this no longer holds good when the higher ground is only a few decimetres above and the distance very great. In the latter case, it is much more likely that the phenomenon is due to capillary action raising masses of water which lie at a constant level in the subsoil. Here the *quantity* of water rising increases with the porosity of the soil, but the *height* to which it reaches (viz. the capillary raising force) is inversely proportional to the porosity. Therefore, on digging several holes of different depths in soil where the " sortume " appear, if the latter is caused by pressure, water will collect in a short time at the bottom of all the holes and will stand at the same level in each, or, if the holes are very far apart, at only slightly different levels (these differences may serve to indicate the direction of the subterranean current, and consequently act as a guide to find the source of the permanent mass of water). If, on the other hand, after a certain time, the bottom remains simply damp as at the surface of the soil, or if water collects only in the deepest holes and in these reaches the same level, it is almost certain that the " sortume " is due to capillary action and that the water level in the deepest holes corresponds to that of the water causing the phenomenon.

Remedies. — When the " sortume " is produced by the pressure of water near-by, it can be located as either more intense on the boundary of the field (in this case it appears by direct infiltration) or confined to the points of strongest pressure (in this case the water is brought by a subterranean channel in the form of a syphon. In the former instance the " sortume " may be got rid of by digging a single deep drainage channel along the edges of the field ; in the second instance the flooded or muddy parts must be connected to the drainage channel by means of trenches, cement piping or underground drains, or else the soil level must be raised by bringing earth to the place.

When the " sortume " is caused by capillary absorption, much deeper ploughing than usual must be resorted to, or at least very deep subsoiling. It would be of still greater value if the deep ploughing were accompanied by very heavy green manuring or by a previous dressing of sand (preferably of a loamy type), which immediately neutralises

the acidity of the soil and in addition permanently increases the porosity, especially in the lower layers, thus forming the most effective barrier against capillary action.

TILLAGE AND METHODS OF CULTIVATION

174 – **A Review of the Literature on Tillage.** — SEWELL, M. C. (Agronomy Department, Kansas Agricultural Experiment Station, Manhattan), in *Journal of the American Society of Agronomy*, Vol. II, No. 7, pp. 269-209, bibliography of 70 publications. Lancaster, Pa., 1919.

The heaviest expense in producing cereal and annual forage crops is on account of tillage : — ploughing and cultivation. The depth and frequency of ploughing, the number of weedings have a material influence on on the cost of production of a crop. The prevailing opinions on the subject are, however, so conflicting that a review of the literature relating to it is most opportune. After recalling to mind the forerunners (TULL, PRIESTLEY), then the classic agriculturists of the 19th century, and lastly modern authors, the author points out that the prevailing theories regarding deep and frequent ploughing are not founded on experimental data and he formulates the following conclusions : —

(1) Ploughing deeper than 7 inches does not generally cause an increased yield.

(2) Shallow ploughing may produce as great yields as deeper ploughing, but the depth less than 7 inches which is best for economic production has not been determined.

(3) There are not sufficient data to determine the expediency of frequent ploughing, but it appears that a suitable rotation of crops enables the number of ploughings to be decreased.

(4) Cultivation may be necessary only to extirpate weeds or to put the soil into condition for absorbing rainfall ; it is therefore, practical, except in very heavy soils, to reduce the amount of cultivation where it is intended primarily to maintain a soil mulch.

(5) Many soils have naturally sufficient aeration, without cultivation, to insure optimum bacterial and chemical activity.

MANURES AND MANURING

175 – **Lime Requirements in the Soil Determined Chemically and Physiologically.** — HARTWELL, B. L., PEMBER F. R. and HOWARD, L. P. (Agricultural Experiment Station of the Rhode Island State College), in *Soil Science*, Vol. VII, No. 4, pp. 279-282. Baltimore, 1919.

Experiments made with lettuce and beet (lime-loving plants) in pots containing a normal soil which had received a copious application of nitrogen, phosphoric acid and potash, plus varying amounts of slaked lime. Liming caused an increase in the yield, but after the maximum crop was reached, further liming did not further increase growth, although the lime requirement of the soil was chemically still considerable. The addition of superphosphate to unlimed pots caused an increased growth in lettuce in spite of a markedly increased lime requirement in the soil as determined by chemical examination. This tends to show that the elimination of the effects of alumina in acid soils is of greater importance than the neutralisation of the acidity.

176 – **The Comparative Value of Various Forms of Agricultural Limestone.** — STEWART, R. and WYATT, F. A. (*Illinois Agricultural Experiment Station*) in *Soil Science*, Vol. VII, No. 4, pp. 273-278. Baltimore, 1919.

The beneficial effect of liming and specially the great value of ground limestone on acid soils has been fully realised in the United States, only within the last few years. There are some questions, however, regarding the use of limestone which remain to be settled: —

(*a*) Can dolomitic limestone be used successfully on acid soils and what is its value compared with limestone containing a high percentage of lime?

(*b*) What is the comparative value of finely ground limestone and coarse limestone which is cheaper?

(*c*) What is the duration of the action of various kinds of lime applied to soils?

(*d*) What effect has the application of limestone on the surface upon the acidity of the subsoil?

(*e*) What is the annual loss of lime from the soil and what are the factors in such loss?

The authors' experiments, made on acid soils, have enabled them to prove that, after the initial acidity has been neutralised, an application of 1 ton per acre of limestone is sufficient to keep the soil alkaline for 4 years and that dolomitic limestone is equally effective. There is no difference in the effect of finely ground and coarsely ground limestone; the latter is even better retained by the soil. Limestone applied on the surface penetrates slowly and, after many years, reaches a depth of 6 to 20 inches but never gets down to the subsoil. The annual loss of lime from the surface layer 20 inches deep varied from 542 lb. to 760 lb. per acre. Among the causes of loss, other than the state of the limestone applied as has been indicated above, are the amount of limestone and its nature. There always remains some lime in the soil which does not act on the acidity, so that the loss of lime may be less than is indicated by acidity determinations.

177 – **The Action of some Common Fertilisers and Manures.** — GREAVES, J. E. and CARTER, E. G. (Utah Agricultural Experiment Station), in *Soil Science*, Vol. VII, No. 2, pp. 121-160, 2 fig., bibliography of 165 publications, Baltimore, 1919.

After a full account of the works hitherto published in scientific literature on the various soil amendments and stimulants, the authors report some laboratory experiments on the action of various salts on the nitrogen and phosphorus of the soil in their various forms.

It stands confirmed that the sulphates of magnesium and calcium, the chlorides of sodium, potassium, magnesium and calcium, the nitrates of potassium, calcium and magnesium, also the salts of manganese and iron generally, can be efficient stimulants of soil fertility.

The stimulating action would be due, in certain cases, to an increase of available phosphorus, in the soil and in others to an increase in nitric nitrogen, increases caused by the action of the salts in question and sufficient to explain the additional yield corresponding to their application.

A remarkable increase is that of nitric nitrogen, which, in the case of sulphate of calcium, may be as much as 97 %. The increase of available phosphorus, either in the form of soluble phosphoric acid or in the form of organic phosphorus, was noted in all cases but two: namely with nitrate of manganese and with carbonate of magnesium. The maximum increase in soluble phosphoric acid was caused with nitrate of magnesium (15.5 %) the increase in organic phosphorus was greatest with carbonate of manganese (62.6 %).

While sulphate of calcium is the strongest stimulant for rendering more nitrogen available, carbonate of manganese acts similarly for phosphorus in the combined increase of its two forms (soluble phosphoric acid and organic phosphorus).

178 – **Ammonia Fixation by Gypsum.** — Bear, F. E. and Workman, A. C. (Department of Agricultural Chemistry and Soils, The Ohio State University), in *Soil Science*, Vol. VII, No. 4, pp. 283-291, figs. 1, bibliography of 21 publications. Baltimore, 1919.

It has been found that the addition of gypsum to manure prevents the volatilisation of ammonia. To verify the truth of this the authors have made laboratory experiments in which they used, instead of manure, filter paper pulped fine and dried; this was intimately mixed with pure sulphate of calcium and a solution of carbonate of ammonium was poured over the compacted material so as to bring the water content of the mixture to 75 %; the proportions of the ingredients were calculated so as to represent 300 pounds of gypsum, in the form of sulphate of calcium, and 19.29 pounds of nitrogen per ton of material. The bottles containing the mixture were heated to temperatures ranging between 20°-85° C., and a current of moist air, freed from which carbonic acid and ammonia, was passed through the mixture into absorbtion bottles containing standard acid solutions; the experiment lasted for 95 days; the aspirations were of 10 minute periods and were made from time to time at intervals ranging from 4 times in 9 days to 10 times in 5 days.

The nitrogen loss at the end of the experiment was 11.84% of the amount applied, while in the case of the experiment without gypsum made simultaneously, the nitrogen loss was 58.29 %. At higher temperatures, above 30° C., nitrogen was lost in a greater proportion and consequently less was retained by the gypsum. Under the conditions in which the experiment was carried out the reaction would be an ordinary double decomposition between the sulphate of calcium and the carbonate of ammonium, a reversible reaction if moisture was decreased; in manure there are naturally more reactions, chiefly subsequent.

To sum up, the treatment of manure with gypsum in the proportion of 300 pounds of sulphate of calcium per ton of manure would effect a satisfactory ammonia fixation when there is enough water to soak the gypsum; whether that ammonia would remain fixed subsequently and whether the addition of gypsum to manure is economical, are questions which are not answered by the authors' experiments.

179 - The Fertiliser Situation in Scandinavia (Sweden, Norway and Denmark) (1)
— SEBELIN, J., in *Nordisk Jordbrugsforsking*, No. 3, pp. 104-126. Copenhagen, 1919.

In the article analysed, the question as to the chemical fertilisers required in agriculture in Scandinavia is dealt with from 3 points of view : —

1) The quantities of potash, nitrogen and phosphoric acid removed from the soil by crops.

2) The quantities of potash, nitrogen and phosphoric acid returned to the soil as manure or excrement ;

3) The requirements in chemical fertilisers, studied also in relation to local production and importation.

DENMARK. — For this country the author uses the data of the Central Bureau of Statistics to calculate the average yield for the period 1909-1913. For a better understanding of the data collected in Table I,, it may be mentioned that the aerial parts of the potato, roots, sugar beet and chicory plants is calculated at $^1/_8$, $^1/_3$ and $^1/_5$, respectively, of the yield in tubers or roots.

NORWAY. — For this country the data of 1917 are used. In order to understand better the figures in Table III it should be remembered that: — 1) the straw of autumn cereals is calculated by multiplying the grain crop of wheat and rye by $\frac{266}{173}$ and $\frac{341}{179}$ respectively; 2) the straw of spring cereals is calculated in the proportion *straw : grain* = 2 : 1.

SWEDEN. — The author makes use of the data of 1913, already elaborated by FEILITZEN (see Table III).

The next table gives a comparison of the quantities of fertilising material removed from 1 hectare in the 3 countries and shows the relation of these to the quantities removed by an average crop and by maximum desirable yield respectively.

The fact that in Sweden the quantity of fertilising material removed from 1 hectare of cultivated land is less than that found for the other two countries is a result of the greater extent and duration of the fallows practised there on the arable land, and also a result of the fact that in the present study no account has been taken, in the case of this country, of the aerial parts of potatoes, root crops and mangolds.

FARMYARD MANURE, DUNG AND LIQUID MANURE. — With regard to the fertilising power of farmyard manure, the manure proper must be distinguished from the liquid. In the latter, the nitrogenous matter exists in easily soluble form and can be used at once by plants, whereas

TABLE III. — *Quantities (in metric tons) of nitrogen, phosphoric acid and potash removed from the soil by the crops in Norway.*

	Total crops	Percentages of			Total quantities contained in the crops		
		Nitrogen	Phosphoric acid	Potash	Nitrogen	Phosphoric acid	Potash
Autumn wheat	247 156	2.00	0.80	0.59	4 943.1	1 977.2	1 235.8

Totals for 3 680 774 hectares of arable land, in m. tons					**143 895.3**	**66 798.6**	**195 436.7**
Totals per hectare of arable land, in kg.					**39.1**	**18.1**	**53.1**

	Nitrogen kg.	Phosphoric acid kg	Potash kg.
Denmark	66.7	27.7	80.7
Norway	41.6	20.6	65.2
Sweden	39.1	18.1	53.1
Average crop	50	24	66
Maximum crop	77.5	30	110

the utilisation of the nitrogenous components of the solid manure is so difficult that these constituents may be neglected in a study of this kind.

The phosphoric acid is found almost exclusively in the solid excreta, while the urine, except in the case of pigs, is practically devoid of it.

The potash is found mostly dissolved in the urine ; the potash of solid excreta may be reckoned as equal to 10 % of that contained in the urine.

Of farm stock, each animal would give per year : —

	Cattle	Horses	Sheep	Goats	Pigs
LIQUID MANURE	2000 kg.	600 kg.	60 kg.	60 kg.	180 kg.
Nitrogen	1 %	1.5 %	2 %	2 %	0.5 %
Phosphoric acid	—	—	—	—	0.15 %
Potash	1.6 %	1.6 %	2.3 %	1.2 %	0.7 %
SOLID MANURE	5000 kg.	3500 kg.	100 kg.	100 kg.	250 kg.
Phosphoric acid	0.15 %	0.3 %	0.5 %	0.5 %	0.25 %

According to these data and on the basis of the live-stock census, Denmark has 50 053 metric tons of nitrogen, 84 749 of potash and 20 435 of phosphoric acid ; Norway 23 762 metric tons of nitrogen, 42 001 of potash and 10 261 of phosphoric acid ; Sweden 55 500 metric tons of nitrogen, 93 491 of potash and 25 592 of phosphoric acid.

The balance of the quantities of substances removed from the soil by crops and of those returned to the soil in the manure, is as follows (in metric tons) : —

	Denmark			Norway			Sweden		
	Nitrogen	Phosphoric acid	Potash	Nitrogen	Phosphoric acid	Potash	Nitrogen	Phosphoric acid	Potash
Crop	171 039	71 619	208 583	31 197	15 130	48 958	1 438 995	66 799	195 437
Manure	50 053	20 435	84 749	25 762	10 261	42 001	55 999	25 592	93 491
Deficit	120 986	51 184	123 834	7 435	4 869	6 957	1 383 396	41 207	101 946
as % of crop	71 %	71 %	60 %	23 %	33 %	14 %	96 %	62 %	52 %

The deficit in Norway is much less than in Sweden and in Denmark ; the reason for this will appear later.

The author also calculates the quantities of human urine and excreta which may add to the manure furnished by animals, thus increasing the available quantities of nitrogen, phosphoric acid and potash. He obtains the following figures : —

	Nitrogen	Phosphoric acid	Potash
	metric tons	metric tons	metric tons
Denmark	5 608	1 419	1 381
Norway	4 923	1 282	1 218
Sweden	11 084	2 900	2 771

The above figures, when added on to the amount of farmyard manure, slightly reduce the deficit, which thus comes down to the following proportions : —

	Nitrogen	Phosphoric acid	Potash
Denmark	67.5 %	69 %	59 %
Norway	8	24	12
Sweden	46	57	50

On account of her greater number of livestock and of inhabitants per unit of area of cultivated land, Norway is in the best position. In each case, however, the deficit is considerable, and if the soil-reserves continue to be drawn upon without compensating for the removal of fertilising material by means of sufficient quantities of chemical manures, exhaustion will eventually follow, with a rapid and continuous decrease in the total crop products.

Chemical Fertilisers. — These may be prepared in the countries themselves from raw material either from home origin or imported, or they may be imported ready-made from abroad. For the three countries and the three necessary elements under consideration, very different conditions are to be observed in this matter.

In *Denmark* nitrogenous manures of native origin are not produced, except for a small quantity of sulphate of ammonia, which in any case is almost all exported. Hence the quantity of manure used is represented only by the import figures. In 1914 there were imported : —

52 592 tons	nitrate of soda	with 15.5 % nitrogen	= 6 602 t.	of nitrogen
10 760 »	synthetic nitrogenous manures .	with 13 % »	= 1 399 »	
695 »	sulphate of ammonia	with 20 % »	= 139 »	
		Total . . .	**8 140** t.	of nitrogen

Of phosphatic manures, the imports for the same year were : —

49 301 t.	phosphorites with about	30 % =	14 970 tons	of phosphoric acid
142 883 t.	superphosphate with about	20 % =	28 572 »	» » »
10 751 t.	basic slag with about	14 % =	1 551 »	» » »
214 t.	bone ash with about	30 % =	641 »	» » »
		Total . . .	**45 734** tons	of phosphoric acid

Of potash, still during the same year, the imports were : —

8 385 t.	Kainit with	12 % =	1 006 tons	of potash
15 284 t.	potash salts with	37 % =	5 565 »	» »
		Total . . .	**6 571** tons	of potash

For *Norway* in 1917 the data for nitrogen were : —

8 969 tons	nitrate of soda with	15 % =	1 435 tons	of nitrogen
8 900 »	» lime with	13 % =	1 157 »	» »
2 800 »	cyanamide with	13 % =	364 »	» »
		Total . . .	**2 956** tons	of nitrogen

In 1917, there were also imported into Norway 37 431 tons of super-

phosphate (= 7 487 tons phosphoric acid), to which should be added 3 400 tons of superphosphate made in the country itself (= 529.4 tons phosphoric acid), or in all 8 016.4 tons of phosphoric acid.

In Norway, potash manures all come from abroad, making a total of 3 500 kilogrammes of potash contained in Stassfurt salt.

In *Sweden*, according to FEILITZEN, 7 108 tons of nitrogen, 35 866 of phosphoric acid and 2 232 of potash were imported as chemical manures, in 1914; in addition FEILITZEN estimates 29 484 tons of "poudrette".

GENERAL SUMMARY. — 1) The utilisation of atmospheric nitrogen, by means of the great water power available in the Scandinavian peninsula, is certainly one of the best ways of meeting the requirements of Scandinavian agriculture. With the half-million HP of the *A/S Norsk Hydro* Company, 40 000 tons of atmospheric nitrogen can be produced in the form of nitrate of lime.

TABLE IV. — *General Summary.*

	Nitrogen	Phosphoric acid	Potash

Deficit or surplus as % of crops	— 49 %	— 3 %	— 39 %

Again, the factories at Odda, in Hardanger, are capable of fixing 13 600 tons of nitrogen in the form of calcium cyanamide, while at present the Fysse and Aura falls are being harnessed, as well as the Bjalve rapids. which will furnish 360 000 H. P. capable of giving at least 108 000 tons of nitrogen.

In Norway a comparatively small quantity of nitrogen can be obtained (1 600 tons) from fish offal.

2) *Phosphoric acid.* — Cropping experiments carried out in different parts of Norway have shown that at any rate some soils need more phosphorus, so that it would be premature to state, without further examination, that this country does not require phosphatic manures, all the more so since the efficient use of animal waste is certainly below that theoretically allowed for in the calculation.

In Sweden and in Denmark the deficit in phosphoric acid is much smaller than that in nitrogen, although the atmosphere is an inexhaustible source of the latter substance, and the sources of phosphorus in these countries are of much less importance. Phosphatic minerals are present in small quantity, and it is only the full utilisation of fish offal (Norwegian fish guano contains almost the same quantity of phosphoric acid as of nitrogen) which could suffice to make good the shortage.

Hence for phosphatic manures Sweden and Dennark are forced to depend on imports.

3) *Potash.* — In respect of this element, Norway is also in the best position, whereas Sweden, and still more Dennark, show a very large deficit. It was hoped to meet the needs for potash by exploiting the felspars that are so plentiful in the Scandinavian peninsula, but so far no result has been obtained in this direction. Complete utilisation of ashes of all sorts could supply potash, but always in very limited quantity.

It should be further noted that, while in Germany 15 kg. of potash are applied per hectare, in Sweden, Norway and Denmark only 6 kg., 4 kg. and 26 kg., respectively, are applied, so that there are posibilities for much larger applications. Hence the importation of potassic material for manure is indispensable.

180 – **The Effects of Manuring on the Yield of Mountain Meadows and Grazing Land.** — Dusserre, C. (Head of the Federal Establishment of Agricultural Chemistry, Lausanne), in the *Annuaire agricole de la Suisse*, Year XX, No. 1, pp. 57-61. Lucerne, 1919.

According to the results of sales by public auction, the sale prices and rents of Alpine grazings have doubled and even tripled in the course of the last few years, in common with the value of the farm stock and its products. Landlords or tenants therefore have to try and get the best they can out of them, neglecting nothing that might increase the yield and quality of the pasture, such as the removal of stones, bushes or weeds, the complete and rational use of the manures made on the holding, etc. Many of these improvements maybe carried out with the labour available on the spot, and in their own interests proprietors and tenants should direct all their efforts to this end. Besides these improvements, the rational use of the commercial fertilisers on mountain meadows and pastures may render services similar

to those rendered for the crops in the plains and valleys. Thanks to the snow which covers the ground during a part of the year and hinders the decomposition of organic matter, the soil of mountain meadows and grazings is usually rich in humus and in nitrogen, so that the use of nitrogenous manures, which cost most, is not often necessary, and restitution may be confined to phosphatic, potash, and fairly often calcareous manures as well. On account of the solvent action on limestone of rain water and melted snow, the surface layer of the soil is often deprived of lime, as the subsoil is not brought up by ploughing ; this frequently happens in the Jura and limestone Alps. Manures containing lime help the decomposition of the humus and make the nitrogen available to growing plants. This explains the generally marked effect of basic slag, which supplies the soil with phosphoric acid and with lime, of which part is in the free state. As a consequence of the more scanty feeding of livestock, since the war began to diminish considerably the import of concentrated feeding-stuffs, cases of rickets and of troubles due to insufficient nourishment of stock are on the increase. Grass that has been treated with phosphatic and calcareous manures, and so is richer in nitrogenous material, phosphorus and lime, ensures better feeding, with a sufficient proportion of the mineral substances necessary for the formation and growth of bone.

Limestone and the soil derived from it is poor in potash compounds, so that potash salts are the best complement to phosphatic manures for it. The same effect can be got with wood ash ; the ashes from the household should be collected and used specially to manure parts of the pasture rich in humus, thus improving the frequently thin herbage.

The making of railways, highways and good mountain roads permits the transport of chemical manures for many pasture lands, and owners of Alpine pastures should profit thereby from all opportunities to cart concentrated chemical manures, to be sown in autumn or in spring as soon as the snow disappears.

Considering the present value of grazings and farm stock and its products, it is obviously necessary to increase the quantity and the quality of the fodder, thus providing for the maintenance of more and better fed stock. The objection that chemical manures would be damaging to the making of good cheese should not prove an obstacle, for, chosen judiciously and sown at the proper time, they cannot have any unfavourable effect on the quality of the milk and of its products.

In order to demonstrate the usefulness of commercial fertilisers on mountain meadows and grazing land, the Federal Establishment of Agricultural Chemistry of Lausanne has had experiments on hand for a long time which are kept up in different districts when circumstances make it worth while. Already the results of a certain number of these have been formulated ; they show that the manures when rationally applied eventually double the yield and, in addition, favour the growth of the good fodder plants (1).

(1) See *R.*, 1917, No. 917. (*Ed.*)

Other trials undertaken in the last few years, at the request of the interested parties, in different districts, show also the extent of the benefit to be derived from the use of chemical manures on mountain meadows and pastures. Thus, for example, on an Alpine pasture the transformation of the flora as a consequence of manuring is seen in the chemical composition of the fodder, which had the following content in crude protein : —

No manure	10.9 %
Superphosphate,	17.0
Superphosphate and potash salt	15.1
Superphosphate and liquid manure.	12.0

Hence, not only the quantity but also the quality of the fodder is greatly improved by the different manurings carried out.

181 – **The Agricultural Value of Organic Manures.** — Russell, E. J. (Rothamsted Experimental Station), in *The Journal of the Board of Agriculture*, Vol. XXVI, No. 3, pp. 228-247, 1 fig. London. 1919.

Review of field experiments made in various places in England with different organic manures (rape cake, guano and shoddy) compared with nitrate of soda, sulphate of ammonia and with farmyard manure, to determine experimentally whether the higher price paid for those organic manures was justified beyond the measure of their content of fertilising elements (nitrogen, phosphoric acid and potash), in view of the fact that hitherto no well-defined field expriments had been made on the subject. From the experiments undertaken at Rothamsted (the most conclusive) with barley, wheat and mangolds, grown continuously on the same ground during 16 years, it appears that the nitrogen from rape cake in equal quantities is not so effective as that from nitrate of soda or sulphate of ammonia when these have been reasonably applied with sufficient quantities of phosphoric acid and potash. Further, rape cake has no residual effect on wheat or barley, while such effect is very marked, for at least 2 years, on mangolds; this is probably due to the strong growth of their leaves which were ploughed into the soil each year.

Rotation experiments also showed that rape cake had little appreciable effect after the year of application.

Experiments on light soils at Woburn also did not show any superiority of rape cake over mixtures of nitrate of soda and other chemical manures.

Comparing, on a basis of equal amounts of nitrogen, the respective effects of Peruvian guano, rape cake and shoddy during the year of application, the values were in the ratio 100 : 91 : 88, with the difference that shoddy had a certain residual effect.

The preference, shown for rape cake and guano is only explained by the fact that they constitute compound manures (rape cake : nitrogen 4.75 %, phosphoric acid 2 % ; Peruvian guano : nitrogen 6 %, phosphoric acid 16 %, potash 2 %) capable of being applied without ill consequences even by inexperienced persons and in a single application, in large quantities (10 cwt to 1 ton per acre in the case of rape cake), where chemical manures would have to be applied in several relatively small doses to avoid

injury, especially to garden crops. Moreover, rape cake and guano are well adapted to the preparation of compound manures and facilitate their use with manure drills.

Although these various reasons may explain the higher prices fetched by rape cake and guano, compared with nitrate of soda and sulphate of ammonia according to their contents of useful elements, they do not, however, allow of valuing that difference in price on the ordinary unit basis. It has been suggested that unit value should be allowed for organic matter, but, according to the author, this would not solve the question since organic matter is not usually applied to the soil in sufficient quantity to exert any appreciable effect; the author is therefore of opinion that the best solution would be to leave prices of organic manures to be settled between seller and buyer, so that they would become in some measure prices of estimation and not quantitative prices (1).

182 – **Analysis of some Organic Manures.** — GUILLIN, R. (Report on the work done at the Laboratory of the French Farmers' Society in 1917 and 1918), in *Bulletin de la Société des Agriculteurs de France*, pp. 171-172. Paris, June, 1919.

During the war, all organic refuse, of small value in normal times and too often thrown away or inefficiently used, has been submitted, on account of the high cost of concentrated manures, to more thorough examination and utilised judiciously according to its composition. The following table shows the average content in fertilising substances of some kinds of refuse frequently used: —

	Nitrogen	Phosphoric acid	Potash
Horse dung	0.45 %	0.40 %	0.45 %
Pigeon droppings	2.75	2.50	1.50
Poultry "	1.10	1.15	0.95
Sheep "	1.80	0.60	2.00
Compost	0.60	0.75	0.70
Dry closet manure	0.60	0.55	0.30
do., desicated (poudrette)	0.90	3.00	0.20
Grape residues	0.75	0.25	0.65
Wine lees	3.50	1.40	8.00
Damaged grain	2.20	1.00	1.30
Damaged bran	2.40	2.30	1.40
Distillery grains	6.00	0.70	0.15
Soot	1.20	0.40	0.20

(1) In these accounts of the effect of organic manures on the soil it should not be overlooked that the author is considering the United Kingdom where the climate is moist and consequently very different from that of sub-humid, semi-dry and dry zones. (Ed).

183 – **Nitrogen Losses in Urine.** — Bear, F. E. and Royson, J. R. (Department of Agricultural Chemistry and Soils, Ohio State University, Columbus), in *Journal of the American Society of Agronomy*, Vol XI, No 8, No. 319-326, bibliography of 7 publications, Lancaster, Pa., 1919

More than half the nitrogen of farmyard manure is contained in the urine, hence the interest of the research undertaken by the authors on the losses of nitrogen in the urine of farm animals, more especially because many agriculturists usually keep the urine in tanks until the time when it is sprinkled on the fields. The expediency of keeping the liquid portion of the manure in this way having been much debated, the authors invetigated the losses of nitrogen from urine ; — (*a*) exposed to the open air ; (*b*) in Bunsen valve flasks ; (*c*) in closed flasks ; (*d*) in closed flasks but with the air replaced by carbon dioxide ; (*e*) absorbed in litter (replaced for the experiment by filter paper) ; (*f*) covered with a layer of kerosene. These experiments showed that urine exposed to the air lost over 92 % of its nitrogen in 8 weeks under temperatures averaging 38° C.; under temperatures averaging 5° less the same loss took place in 12 weeks. Urine not exposed to air lost on the other hand little or no nitrogen. Regarding the method of preventing loss of nitrogen by absorption in litter the effectiveness depends on the manipulation ; when the litter was allowed to dry there was a loss of 20 % of nitrogen, but when it was kept moist the loss was 97 %, the maximum observed in the different experiments. The use of kerosene for covering the urine is a good means of preventing loss of nitrogen, for in this case the losses were not greater than 6 % during 8 weeks.

184 – **The Phosphate Deposits in Switzerland and their Utilisation in Agriculture.** — Tounginger, E. (Mitteilung aus der schweizerischen agrikulturchemischen Anstalt Bern), in *Landwirtschaftliches Jahrbuch der Schweiz*, Year XXXIII, No. 3, pp. 288-312. Lucerne, 1919.

Up till now no phosphate deposits have been discovered in Switzerland of sufficient importance to supply the country with all the phosphoric acid it needs. The only phosphorite beds of any extent are those in the gault at Buchs-Werdenberg in the canton of Saint Gall ; their contents are estimated at about 20 000 tons of phosphoric acid, but the thinness of the seams, the hardness of the material and many faults make it difficult to work them. Experiments in the preparation of superphosphate. (with sulphuric acid left after the manufacture of explosives or with bisulphate of soda) carried out with this material have not given at all satisfactory results, both on account of unfavourable conditions arising out of its chemical composition (about 10 % phosphoric acid) and on account of its physical texture.

With regard to the use of the natural Werdenberg phosphorite finely ground as a manure, trials made up to the present in the field and in pots under favourable conditions do not allow of a definite conclusion being arrived at.

185 – **The Palms of the Philippine Islands.** — BECCARI, O., in *The Philippine Journal of Science*, Vol. XIV, No 3, pp. 295-362, 2 pl. of 10 fig. Manila, March, 1919.

The species of palms at present known to be indigenous to the Philippines number about 120, not including a few semi-wild or cultivated forms. Of that number there are a dozen species of relatively wide geographical distribution, all the others being endemic forms. Among the non-endemic forms, some are derived from species growing in swamps or at the mouths of rivers, along the coasts of neighbouring countries, others have been introduced by man or other means.

The author, after giving a list of all the species and varieties of palms known in the Philippines, describes them botanically one by one.

186 – **The Grasses of Illinois, U. S. A.** — MOSHER, E., in *University of Illinois Agricultural Experiment Station, Bulletin*, No. 205, 425 pp., 285 figs., bibliography of 23 works (including only those which mention grasses of Illinois). Urbana, III, Mark, 1918.

This is a fully illustrated monograph on the grasses of Illinois dealing with structure of the grasses; key to the genera of Illinois grasses; brief description and observations on the grasses found in this State. A list and description is given of 204 species representing 63 genera; 43 species are listed in it for the first time as occuring in Illinois.

187 – ***Agave Cantula* Roxb. from the Botanical Point of View: Origin, Distinction from *Agave americana*, Synonomy.** — See No. 203 in this *Review*.

188 – **An Asclepiad of the genus *Araujia* Dangerous to the Insects that Ensure its Pollinisation.** — RICÔME H., in *Comptes rendus de la Société de Biologie*, Vol. LXXXII, No. 25, pp. 1045-1047. Paris, Oct. 18, 1919.

As is well known, in Asclepiads the cross fertilisation carried on by insects takes place owing to the fact that the retinacula adhere to the head of the insect, carry with them the pollen.

The author calls attention to a climbing asclepiad of the genus *Araujia*, grown in gardens, the pollen-bearing flowers which are visited by bees, winged ants and day and night moths such as the Sphinx hawk-moth.

In order to reach the nectar, the insect has to insert its proboscis between the stamens and corolla; then the proboscis is withdrawn easily, the retinacula trodden by the fore feet, adhere to the tarsis, and cross — pollination is assured. But often the insect inserts its proboscis, not outside the stamens, but between one of the retinacula and the contiguous borders of two adjacent anthers. The retinaculum has a viscous groove which closes on the proboscis and holds it, and the insect is captured and dies of starvation. Even vigorous insects like the bee and sphinx moth are powerless to free themselves, as the flower has a stamen and carpel arrangement such that the more the insect struggles the firmer the part of the proboscis caught is held between the anthers, as if in a vice.

In the author's opinion, considering the large number of insects captured, this plant should not be grown near places where bees are kept.

189 – **The Composition of Cereal Grains: Mistakes made in Locating the Chemical Constituents of Wheat and Rice Grains; Aleurone.** — G. VARESCHI, I., in *Annali della R. Accadèmia di Agricoltura di Torino*, Vol. LXI. pp. 3-31. Turin, 1918.

The author examines critically several of the commonest treatises on botany, showing their mistakes regarding the location and nature of the chemical constituents of wheat and rice grains. He makes out that several authors confuse between aleurone (a mixture of albuminoids not yet well defined and separated) and gluten (a mixture of at least 5 albuminoids, among which glutenin and gliadin, especially the latter, are typical), and he draws the following conclusions from his work: —

1) True gluten is found only in wheat and rye grains.

2) The albumen or kernel of wheat, rice and the other cereals contains not only starch but also always albuminoid material (gluten and non-gluten).

3) The gluten, whether previously formed or not, exists with the starch in the albumen and not in the so-called " aleurone " layer, and in much more minute quantities in the outer coats. In wheat-seed albumen, starch does not exist alone, but is always associated with gluten. The quantity of gluten increases from the middle towards the outside of the albumen ; it has not yet been proved whether the gluten pre-exists in the albumen or is formed by the action of water.

With the following reagent : 1 gm. Hofmann violet + 50 gm water + 6 to 8 gm. sodium bisulphite + 9 to 10 cc. hydrochloric acid at 1.19, it is easy to recognise the albuminoid materials in flour.

4) It is easy to separate gluten from starch in wheat, but difficult to separate albumoid from starch in rice.

Rice contains glutenin, glutencasein, glutenfibrin, edestin or phytovitellin, but not gliadin, which is typical of true gluten. On the other hand, rye, like wheat, contains gliadin, glutenin and conglutin (which appears to be identical with edestin) ; it therefore contains a true gluten.

5) It is erroneous to state that aleurone is synonymous with gluten.

6) The term " aleurone " should be abolished, so as not to cause confusion, and replaced by the generic name " albuminous or protein matter ".

190 – **Seasonal Variations in the Chemical Composition of Seaweed.** — LAPIQUE, LOUIS, in *Comptes rendus de l'Academie des Sciences*, Vol. LCXIX, No. 26, pp. 1426-1328. Paris, Dec. 29, 1919.

While pursuing studies on behalf of the Inventions Department (1), on seaweed as considered from the food point of view, the author found a considerable seasonal variation, affecting the value of these plants as raw material for several purposes. He took *Laminaria flexicaulis* as a typical marine alga. He found that from springtime onwards the cell sap became richer in laminarin and mannite, and became proportionately poorer in salts. It is easy to imagine that such is the result of the chlor-

(1) See *R.*, Feb., 1919, No. 225. (*Ed.*)

ophyl action in relation to light, of which the seasonal difference must be still greater under water than on land.

PLANT BREEDING

91 - **Behaviour of the Characters "Date of First Head", "Height of Plant" and "Width of Leaf" in certain Crosses between Hard, Medium and Soft Wheat in the United States.** — FREEMANN, GEO. F., in *Genetics*, Vol. IV, No. 1, pp. 1-93. Princeton, New Jersey, Jan., 1919.

Results of a long series of experimental researches on the transmission of the characters date of the first head, height of the plant and width of the leaves, in some hybrids between soft wheat and hard or medium wheat.

MATERIAL USED. — *Hard Algerian* (No. 1) : — late, tall ; stems large, stiff ; leaves broad, medium width, dark green ; heads large, long, slightly flattened ; glumes bearded, pubescent, light yellow ; grain large, translucent, very hard ; some grains have sometimes spots of opaque starch in the endosperm.

Red Algerian medium. — Late, tall ; stem medium sized ; leaves medium in width and colour (green but not very dark) ; heads medium sized, square ; glumes bearded, glabrous, light yellow ; grain red, medium hard opaque.

Early Baart. — Early, low ; stem medium sized ; leaves medium in width, green ; heads medium sized, square ; glumes bearded, glabrous, light yellow ; grain white, opaque, soft.

Sonora (No 35). — Early, low ; stem medium sized ; leaves broad, light green ; heads cylindrical, medium sized ; glumes beardless, pubescent, redd sh brown ; grain white, opaque, soft.

DATE OF THE FIRST HEAD. — *Hard Algerian* (No. 1) × *Sonora* (No. 35). — The average date of the first head of the parents and the hybrids in F_2 may be summed up as indicated in the following Table, where the number entered in the columns represent the *cultures*, or groups of plants originating from a single plant ; thus in the column March, 25-26 the number 7 signifies that this date is the average date of the first head for 7 distinct *cultures* of the F_2 generation.

	March							April			
	17-18	19-20	21-22	23-24	25-26	27-28	31-1	2-3	4-5	6-7	8-9
No 35	—	2	1	—	—	—	—	—	—	—	—
(1 × 35) F_2	—	—	—	1	7	17	12	—	—	—	—
No 1	—	—	—	—	—	1	4	1	2	1	—

The hybrids in the F_2 generation thus show themselves 3 days later than the earlier of the parents and 4 days earlier than the latest of the parents.

There were the following standard deviations (σ) of the whole population : No. 35 = 2.14 ; No. 1 = 3.30 ; (1 × 35) F_2 = 4.00.

For F_3 there were the following average dates : —

	March				April											
	25–26	27–28	29–30	31–1	2–3	4–5	6–7	8–9	10–11	12–13	14–15	16–17	18–19	20–21	22–23	24–25
No 35.	—	4	1	—	—	—	—	—	—	—	—	—	—	—	—	—
(1 × 35) F_3 . . .	3	2	4	6	8	13	17	21	33	58	38	8	13	3	3	—
No 1	—	—	—	—	—	—	—	—	—	2	3	2	—	—	—	—

The standard deviations of the whole population were : — No. 35 = 1.34; No. 1 = 1.99; (1 × 35) F_3 = 6.24. The high value of the deviations in the F_3 generation can only be explained as the effect of special climatic conditions. The author explains the phenomenon in the following manner : — from one generation to the next the number of homozygotes tends to increase, while the number of heterozygotes decreases and they tend to take an intermediate position (in approaching the average value), hence there results, as a natural consequence, an increase in the extreme values.

Among the hybrids in F_3 three cultures were earlier than No. 35 (the earlier of the parents) and 19 were earlier than No. 1 (the later of the parents) Would it then be possible by recombination of the characters to isolate races earlier or later than the parents themselves ? Before answering such a question the results of another cross *Red Algerian medium* (No 3) × *Early Baart* (No. 34) should be examined. So far as the average dates of the first head in F_2 and F_3 are concerned, much the same results as in the previous case were recorded : the hybrids tend to take an intermediate position with respect to the parents and the standard deviation increased largely from the F_2 to the F_3 generation as effect of the decrease in heterozygosity. The following Table illustrates this point.

	March						April						
	21–22	23–24	25–26	27–28	29–30	31–1	2–3	4–5	6–7	8–9	10–11	12–13	14–15
No 3 . . .	—	—	—	—	—	—	—	—	—	—	—	3	2
(3 × 34) F_3	—	—	1	12	9	14	15	21	9	6	10	7	8
No 34. . .	1	1	2	1	—	—	—	—	—	—	—	—	—

The means of the hybrid cultures all fall within the mean limits of the parents. In this case recombination of characters has not brought about the appearance of new types superior in earliness or lateness to the parents (contrary to what appeared to exist in the previous case).

According to the Mendelian theory. the plants of the F_2 generation having a closer relationship with the hybrids of F_1 (heterozygotes in the

highest degree) ought, in F_3, to produce much more variable descendants (for the greatest possible number of combinations) than the hybrids of F_2 with a genetic constitution further removed (greater homozygosity) from that of the plants of the F_1 generation. That this has not taken place in many cases is due to the fact that many combinations theoretically expected are, in pratice, incapable of growth or sterile, so that the variation curve corresponds only to part of the descendants.

The phenomena observed can be explained by the existence of at least 3 factors governing the date of the first head. No attempt has been made to determine the number of factors acting in each case but the fact that many of the groups with intermediate characters show cultures with low variability would indicate that the number of factors concerned was very high, thus making it possible to obtain some types genetically different but still homozygous.

HEIGHT OF THE PLANTS. — The material for examination in this enquiry came from 4 crosses:— *Hard Algerian* (No. 1) × *Sonora* (No. 35); *Hard Algerian* (No. 1) × *Red Algerian medium* (No. 3); *RedAlgerian medium* (No. 3) ×*Sonora* (No. 35); *Red Algerian medium* (No. 3) × *Early Baart* (No. 34).

The examination of the plants in F_2 and F_3 gives the impression, so far as the character "height" is concerned, of two antagonistic forces: — (1) heterozygosis, which causes the plants in F_3 derived from hybrids of F_2 to resemble the hybrid of F_1 (that is to say of F_2 with the greater number of pairs of characters in the heterozygous state), much more variable than those descending from the hybrids of F_2 where the homozygous pairs prevail; (2) another force which tends to suppress variability in the *tallest* cultures.

Admitting that all the plants in F_1 were genetically equivalent, the descendents in F_2 of the several cultures ought to have the same averages and the same coefficient of variability in all cases, as can be seen from the adjoining Table:—

An examination of these data shows that the variability in the tall classes is less than in the low classes, but the differences, though small, are constant and indicate the presence of a factor suppressing the variability even of the taller cultures. The presence of this suppression factor is still more clearly indicated in the cultures of the various parents taken separately:—

Having thus proved the existence of a factor which may reduce the variability of the taller cultures, independently of heterozygous condition, the observed facts may be explained as follows (1): This factor has completely masked the effect of heterozygosity in the cross 3 × 34, in which the F_2 and F_3 cultures had an average height greater than that of the taller parent.

(2) This factor has partly suppressed, but not completely masked, the variability due to heterozygous conditions in the cross 3 ×35, in which the F_2 and F_3 cultures were approximately as tall as the taller parent.

(3) The effect of this factor is still evident in the crosses in which the F_2 and F_3 cultures showed heights less than those of the parents

		Average heights in cm. (1915)					
		100–109	110–119	120–129	130–139	140–149	150–159
(1 × 35) F_2	Number of cultures	—	4	30	4	—	—
	Average coefficient of variability	—	19.2	19	18.9	—	—
(1 × 3) F_2	Number of cultures	2	1	1	1	1	—
	Average coefficient of variability	28.5	20.2	10.4	14.5	—	—
(3 × 34) F_2	Number of cultures	—	—	—	—	2	4
	Average coefficient of variability	—	—	—	—	5.5	4.8
(3 × 35) F_2	Number of cultures	—	—	—	1	9	8
	Average coefficient of variability	—	—	—	7.0	5.9	6.0

		Average heights in cm.				
		110–119	120–129	130–139	140–149	150–159
No 1	Number of cultures	—	2	4	6	4
	Average coefficient of variability	—	7.5	7.5	6.5	5.
No 35	Number of cultures	3	3	1	1	—
	Average coefficient of variability	6.7	6.7	6.4	3.9	—
No 3	Number of cultures	—	2	3	1	—
	Average coefficient of variability	—	7.5	5.6	4.2	—
No 54	Number of cultures	1	4	1	—	—
	Average coefficient of variability	6.9	6.1	4.8	—	—

without being, however, sufficiently intense to mask the effect of heterozy gosity. Having thus defined the disturbing action of the factor suppressin variability, all the other facts can be, are very simply explained on th hypothesis of the segregation and recombination of a certain number c simple Mendelian unit characters.

WIDTH OF LEAF. — For this character also, as in the case of height, facts were observed which can only be explained on the hypothesis of the existence of a factor which, in spite of heterozygous conditions, tends to suppress the variability of cultures with very wide leaves. In these cultures, the coefficient of variability is less than in cultures with narrow leaves.

Three questions suggest themselves:—

(1) Can it be that the coefficient of variability is not a proper measure for the exact determination of the variability of quantitative characters in biology?

(2) Can it be that even the purest lines of wheat are partly heterozygous and that among them the lines which are tall and with wide leaves are more homozygous than the others?

(3) Can there, perhaps, be some physiological limitation of growth in the higher (wider) classes which prevents the full development and expression of certain over-complicated recombinations of characters?

The author inclines in that case to (1) and (3). If a car is moving at a speed A and an additional force $F + m$ is applied which produces a speed $A + n$; to produce a speed of $A + 2n$, a force greater than $F + 2m$ would be required. The effect of a factor (environ mental or genetic) for increasing size becomes attenuated, it would seem, in combinations which tend to produce values higher than the general average of the race. And vice versa the action of the same factor would be more strongly marked in gametic combinations which tended to produce values lower than the average value of the race. It is possible, therefore, that the variability of quantitative characters may be better measured by the coefficient derived by dividing the standard deviation by some fractional power of the mean:—

$C_1 = \frac{\sigma}{M^x}$, where x is a quantity less than 1.

So far as other factors are concerned in the case of width of leaf, as in the case of height of the plant, the observed facts can be explained in accordance with Mendelian laws by the segregation and recombination of the characters. These factors, wich are certainly numerous, have not yet been determined.

192 – **New Types of Wheat, Rye and Oats obtained by Hybridisation and Selection at Svalof, Sweden.** — NILSSON, N. HJALMAR, in *Sveriges Utsädefärenings Tidskrift*, Year XXIV, No. 3, pp. 116-117. Malmo, 1919.

"203, *Birgitta*, 086" is a new kind of wheat obtained by crossing Smaahvede and Extra Squarehead II. From comparative cropping tests carried out in Östergötland it was found to be superior to Sol II in grain yield; it is much more resistant to attacks of the rhynchote *Cicadula* (*Jassus*) *sexnotata* (1). In earliness it shows itself equal to the Sol variety, and is a type of wheat especially suited to the fertile land in the Östgöta plain.

(1) See *R.*, June 1915, No. 648. (*Ed.*)

" 204, 0955 ". This variety of wheat, the result of the cross Pansar × Fylgia, is destined to replace the Fylgia variety, to which it is plainly superior in its greater resistance to the rigours of winter and to rust and in the greater strength of its straw. It ripens earlier than the Pansar variety, and at the same time as Fylgia wheat.

" 205, *Stål*, 0302 ", is a new variety of rye obtained as a pure line (by genealogical selection) from the Stiärn varieity, from which it is distinguished by its rather shorter and more robust straw, but it remains equal to the original variety both in quality of grain and in yield.

" 209, 01180, *b* " is a new variety of oats obtained from the cross Seger × Kron, destined to replace the Kron variety.

" 210, 01171, *b* " is a new variety of oats from the cross Seger × Gul Naesgaard and is destined to replace the Seger variety.

193 – **Observations on the Heredity of Characters in the Lupin, Wheat and Barley, in Denmark.** — VESTERGAARD, H. A. B., in *Tidskrift for Planteavl*, Vol. XXVI, No. 3. pp. 491-510 + 7 figs. Copenhagen, 1919.

LUPIN. — *Colour of flowers.* — *Lupinus angustifolius* generally has blue flowers, but some individuals have red and others white flowers.

These 3 types keep constant and separate in their progeny, cases of cross pollination by insects being very rare.

By crossing plants white flowers (♀) with plants with blue flowers (♂), in the F_1 blue individuals were obtained, and in the F_2 blue individuals and white individuals in the simple Mendelian ratio 3 : 1, as if the difference between the two types were due to the presence of a blue, factor dominant compared with its absence.

The author next made the cross *white* ♀ × *red* ♂. In the F_1 he obtained hybrids with white flowers instead of red as would have been expected on the basis of a simple factor. The F_2 was composed of specimens with blue, red and white flowers, respectively, in the proportion 9 : 3 : 4. The phenomenon may be explained by allowing that, in order to produce the blue, not a single factor is necessary, but two, **B** and **R**.

In the presence of the single factor **B**, the flowers remain white, while in presence of **R** only, they take on a red tint.

In the case studied, the white type therefore should have the genetic constitution **BBrr**, and the red type the constitution **bbRR**, from which in the F_2 the formula **BbRr** (with blue flowers) is obtained. Such a hybrid produces 4 kinds of gametes : — **BR, Br, Rb,** and **br**, which, when combined with one another, give 16 possible combinations in the F_2, namely : —

1 **BB RR** + 2 **BB R r** + 2 **B b RR** + 4 **B b R** *r* . . = 9 *blues*
1 **bb RR** + 2 **bb R r** . . . . . = 3 *reds*
1 **BB rr** + 2 **B b r r** + 1 *bb* **rr** . . . . . = 4 *whites*

The crosses *red* × *white* were also made and results obtained which are quite explicable on the basis of the above scheme : the F_2 is composed of plants with blue and red flowers respectively in the proportion 3 : 1.

WHEAT. — *Appearance of loose-eared plants in pure varieties of compact-eared wheat.* — Starting point: — 40 pure varieties of " Abed " wheat with close ears (1914). In one of these lines, composed of about 50 plants with typically compact ears, a specimen with loose elongated ears was picked out.

From this plant, in 1915, there were derived 27 compact-eared and 27 loose eared plants, each lot clearly separate from the other. The former had 2 stems per plant, the latter 14 stems, that is, a lower tillering along with greater length in the stems ; consequently the latter were less robust.

The following table shows the differences observed between the two types :

	Compact-eared type	Loose-eared type
Number of stems per plant	2.0 — 2.2	1.4 — 1.6
Height of stems. cm.	127	135
Length of ear. cm.	8.26	9.50
Number of spikelets	19.3	18.0
Average distance between two spikelets mm.	4.3	5.3

Of each of these types, 10 pure lines were sown. The 10 lines derived from the compact-eared type gave, in 1916, compact-eared plants, while the 10 lines derived from the abnormal type gave a mixed progeny of compact-eared and loose-eared plants.

In 1917, the same phenomena were repeated ; in no case were constant loose-eared pure lines obtained.

In 1918, in a culture, besides the two loose-eared and compact-eared types there appeared also a third type with short stems and very short and compact-ears, which greatly resembled " Kubbe " wheat (*Triticum compactum*).

This 3rd type, represented by a single specimen, in 1919 gave a progeny including, besides the 3 above-mentioned types, also a 4th type, which was dwarf.

BARLEY. — *Crossing dwarf forms and normal forms.* — In 1915 the author crossed " Binder " barley with a dwarf barley derived from the mutation of a pure line of 2-row barley.

In the F_1 the hybrids resembled the " Binder " parents ; the F_2 contained normal and dwarf plants respectively in the very doubtful proportion 6 : 1.

Transmission of abnormal characters. — Plants having giant ears, mostly empty and misshapen, which were isolated in 1916, gave in 1917 a progeny composed of 36 abnormal and 4 normal specimens.

In 1918, the seed of 10 of the 36 abnormal and of 2 of the 4 normal specimens was sown, and there were obtained, in the former case, exclusively abnormal progeny, and in the latter case mixed progeny: No. 1 = 35 normal + 8 abnormal, and No. 2 = 22 normal + 8 abnormal, that is, in all, 57 normal and 16 abnormal, in the proportion 3.35 : 1.

Hence this anomaly is a recessive property with respect to the domin ant normal form.

The two plants of normal aspect were, therefore, of hybrid nature, a also the mutant of 1915 must have been, from which in 1916 there wer derived the plants in which the anomaly was visible.

194 - **The Selection of *Hevea brasiliensis* according to Individual Difference in Yield.** — I. WHITBY, STAFFORD, in *Bulletin of Miscellaneous Information, Roy Botanic Gardens, Kew*, No. 8, pp. 317-318. London, 1919. — II. MASS, J. G., in *Mede deelingen van Algemeen Proefstation der A. V. R. O. S., Rubberserie* No. 21, pp. 1-2 Medan, August, 1919.

I. — These are the results of a series of observations made in the Fe derated Malay States on the specific differences in the amount of rubbe yielded by individual trees of *Hevea brasiliensis* of the same age and growin under the same conditions, in order to establish also whether there exist a correlation between the yield and the girth of the trunk. Some 100 trees, 7 years old, in a normal plantation covering 13 acres, were care fully studied, the trees being in their third year of tapping.

Great variations were found in the rubber content of the latex (th " strength " of the latex) from different trees, and appeared to be constan from year to year. Some trees yielded 23 gm. of rubber per 100 c.c. o latex, others as much as 54 to 55 gm. per 100 c.c. of latex, the mean fo the 245 trees examined being 39.58 gm. per 100 c.c.

The rubber content of the latex increases as the trees grow older, t the extent of 1-2 per cent. per annum.

The author admits the possibility of obtaining good positive result from selection based entirely on individual variations : if high-yielding tree can be segregated and provided that pollen of poor-yielding trees can b prevented from gaining access to the flowers, it should be possible to ge seeds capable of producing trees with a high percentage of rubber in th latex. There is a definite correlation between girth and yield, but it is no sufficiently well indicated to be of great value in eliminating trees from a plantation.

II. — In Hevea plantations there are good and bad yielding trees. Fo 5000 trees 8-9 years old, the mean daily yield of latex was 22 c.c. Eighty pe cent. of these trees gave on the average $\pm$ 10 c.c., while the remainin twenty % alone produced 65% of the entire yield. It is to be inferred fro these results that productivity is a hereditary character.

On the other hand, in plantations, free cross-pollination mixes goo and bad elements in the most varied of genetic combinations, while complet segregation of the best specimens involves very great difficulty from th technical and practical point of view.

The author urges the suitability of vegetative propagation of the bes yielding trees, by grafting on to the young plants slips from specimens tha have been under careful and continuous control and are notable for thei high yielding properties.

It is a case of repeating with *Hevea brasiliensis* that which is bein

tried at present with coffee and cacao in Suriman and has already been carried out on a large scale in the United States citrus plantations.

195 – **Apple Bud Selection and Selection of Apple Seed for the Propagation of Apple Seed.** — CRANDALL, CHARLES S., in *University of Illinois Agricultural Experiment Station, Bulletin* No. 211, p. 180-264, 42 fig. Urbana, Illinois, June, 1918.

Results of a series of experiments made since 1907 with the object of establishing : —

(*A*) Whether, when selecting apple buds, account should be taken of the size of the buds and of their position on the tree and on the branch.

(*B*) Whether apple seedlings obtained from seed taken from large apples are better than those produced by seed taken from small apples.

(*A*) SELECTION OF THE BUDS. — (1) *Large buds and small buds.* — For estimating the effect of selection of the bud, the annual growth of the plants (produced from the buds) was measured in inches. The following Table sums up the principal data : —

Variety of Apple	Size of bud	Average growth in inches							
		1908	1909	1910	1911	1912	1913	1914	1915
Yellow transparent	Large	21	11	11	37	40	53	74	92
	Small	17	6	9	42	50	60	72	93
Oldenburg	Large	15	26	11	46	49	63	70	92
	Small	11	20	12	37	45	58	72	93
Grimes	Large	19	20	9	42	51	64	80	102
	Small	21	16	8	38	47	53	64	90
Winesap	Large	28	17	9	46	55	70	88	116
	Small	21	10	11	46	56	72	89	113
Ben Davis	Large	28	19	9	43	52	64	78	98
	Small	20	21	7	46	56	69	84	109

Note. — Total growth (leader and branches) is given for 1908 and 1909; growth of leader only for 1910 ; total height of the plant for each succeeding year.

As an examination of these data proves, there is nothing in them, at least so far as vigour of growth is concerned, that points to any difference due to the size of the buds for grafting.

(2) *Position of the bud on the tree.* — The buds for propagation were divided into 4 classes for this purpose : —

(*a*) Terminal buds from central terminal shoots.

(*b*) Terminal buds from extreme lateral shoots on the south side of the tree (in full exposure to the sun).

(*c*) Terminal buds from extreme lateral shoots on the north side of the tree and for the most part shaded.

(*d*) Terminal buds from short interior branches.

(*e*) Terminal buds or scions from centrally located water sprouts.

In this case, as in the former, the selection of the buds had no influence on the subsequent growth. The growth curves are essentially the same for *a*, *b*, *c*, *d*, and *e*.

(3) *Position of the bud on the shoot.* — For this purpose the selected buds were divided into 4 classes: —

(*a*) Terminal buds.
(*b*) Lateral buds from the top extremity of the shoot.
(*c*) Buds from the middle of the shoot.
(*d*) Buds from near the base of the shoot.

From the data collected in tabular form and also in graphs no relation is shown to exist between the position of the bud on the shoot and vigour in growth.

Conclusion. — The size and the position of the bud do not give any indication to help selection.

(*B*) SELECTION OF SEED. — The fruit was classed as "large" and "small" on a basis of the size; all fruits having transverse diameters of 65 mm. or more were classed "large" and those having transverse diameters of 64 mm. or less were classed "small". The following Table relates to the varieties Grimes and Jonathan: —

	Grimes		Jonathan	
	Large	Small	Large	Small
Average weight . . . . . gm.	130.70	106.31	141.46	93.83
Average transverse diameter . . mm.	66.00	62.00	70.91	60.59
Average longitudinal diameter . mm.	57.00	—	60.31	52.26

From the many data collected regarding the vigour of growth of the plants, it appears that plants grown from seed taken from large apples are more vigorous and resistant to disease and adverse conditions than those grown from seed taken from small apples.

CULTURAL SEEDS

196 – **The Activity of the "Federazione dei Consorzi Agrari Italiani" for the Production of Pure Seeds in Italy.** — *Giornale di Agricoltura della Domenica*, Year XXIX-No. 33, p. 238. Piacenza, August 17 1919.

In 1918. the "Federazione dei Consorzi agrari" (Federation of the agricultural consortia) initiated a programme which consisted essentially of the following two points: — 1) to encourage adaptation tests, in different regions, of selected varieties from the plant-breeding stations; 2) to encourage the industrial production of seeds, both by farmers and by their associations.

For the purpose of the adaptation tests, in 1918 about 350 quintals of wheat seed were got, of the best pure varieties obtained by M. TODARO, of the Bologna Plant-breeding Station, by M. STRAMPELLI, of the Rieti Station, and by M. PASSERINI of the Scandicci Institute. These seeds were distributed to some of the principal agricultural associations for experimental

trials. The aim of the trials was to ascertain the ability of the varieties to become acclimatised to the different conditions and different parts of the country, and to compare each of them with the original non-pure variety Four varieties segregated at the Bologna Station, of the types *Gentile* (family 48), *Colognese* (families 12 and 10), *Inallettabile* (fam. 38) and *Marzuolo* (fam. 83), as well as *Carlotta Strampelli* (obtained at the Rieti Station) and the hybrid *Noé* × *Gentil rosso*, were reserved for north Italy and part of central Italy. In south Italy (province of Lecce) experiments were carried out with the varieties of wheat known as *Luigia Strampelli, Apulia, Dauno, Nuovo Gargano, Selezionato Maiorca*, and also *Maraini* barley from the Rieti Station. There were 38 centres for adaptation tests, with a total of 106 plots. The plots were inspected from the second week of May up to July 8 to 10. These tests provided the first material which the Federation will make use of in order eventually to set up model centres for the production of the best varieties of seeds.

CEREAL AND PULSE CROPS

197 – **Investigations on Wheat Siftings.** — Savini, G., in *Le Stazioni sperimentali agrarie italiane*, Vol. 32, Nos. 7-9, pp. 361-374. Modena, 1919.

The paper deals with the work done at the central chemical laboratory of the Customs and Direct Contributions Department in Rome on wheat of different origins : various districts of Italy, Rumania, Russia, Argentina, Australia, British India, Morocco and North America. In all, 35 samples of soft wheats and 14 of hard wheats (the latter being mostly of Russian origin) from the 1913 and 1914 crops were examined. It could be taken for certain that none of the samples examined had undergone any cleaning process after threshing.

Conclusions. — The commonest seeds found in wheat siftings are, in alphabetical order : *Agrostemma Githago, Avena sativa, A. fatua, Convolvulus arvensis, Galium tricorne, Gladiolus segetum, Hordeum vulgare, Lolium temulentum, L. perenne, Lathyrus aphaca, Polygonum convolvulus, Saponaria vaccaria, Secale cereale, Sinapis arvensis, Vicia sativa, V. villosa, V. sylvatica.*

Less common, are seeds of : — *Adonis aestwalis, Bifora radians, Bupleurum protractum, Coronilla varia, Eroum ervilia, Lithospermum arvense, Medicago sativa, Melilotus sulcata, Muscari botryoides, Ornithogalum umbellatum, Rapistrum rugosum.*

Still less common are seeds of : — *Bromus secalinus, Camelina sativa Caucalis daucoides, Cirsium arvense, Centaurea Cyanus, Lolium italicum, Phalaris canariensis, Ranunculus arvensis, Scandix PectenVeneris, Setaria glauca, Sinapis nigra*, etc.

Out of 35 samples of hard wheats and 14 of soft wheats examined, only 3 contained, in very slight proportions, seeds of *Melampyrum arvense*, which are poisonous.

A large part of the commonest seeds is cosmopolitan, such as *Avena sativa, Agrostemma Githago, Convolvulus arvensis, Galium tricorne, Lathyrus aphaca, Sinapis arvensis, Polygonum Convolvulus*, etc.

Others are found only in Italian wheats, such as : — *Alopecurus*

agrestis, Bifora radians, Bupleurum protractum, Gladiolus segetum, Phalaris canariensis,

The following seeds are almost entirely absent from Italian wheats and are found mostly in foreign wheats : — *Camelina sativa-Saponaria Vaccaria, Setaria glauca, Sinapis nigra,* etc. Seeds of *Alopecurus agrestis* were found only, and then in abundance, in 5 samples from the district of Rieti (Italy).

Rumanian wheat is almost always notable for the large quantity of rye and corn-cockle found in it, and Russian soft and hard wheat for the presence of barley, *Polygonum Convolvulus* and *Saponaria vaccaria.*

As regards total percentage, the siftings oscillate between a maximum of 75 gm. per kg. (Moroccan wheat) and a minimum of 2 gm. per kg. (British Indian wheat). On the average, Italian wheat contain not more than 2 % and foreign wheats not more than 3 % of siftings.

198 – **Rice-Growing in Greece.** — PAPAGEORGIOU, P. (Director of the Royal Greek Society of Agriculture), in *Annales de Gembloux,* Year XXV, No. 3, pp. 93-97. Brussels, 1919.

Rice is not an important crop in Greece, but it is nevertheless true that rice is a paying crop where soil conditions (nature and exposure of the land) and water supply (springs, streamlets, etc.) are suitable, and in any case a duty of 24.65 francs per 100 *okes* (125 kg.) on imported rice favours home production. Some years ago, rice crops were of greater area in Greece than at present, because low-lying and marshy ground was then cultivated. Following on the State prohibition of this crop in places where there was stagnant water, with the object of diminishing the causes of malarial fever, rice cultivation had to be limited to healthy and irrigated ground. Thus, as regards the ancient kingdom, the crop is grown almost entirely in Thessaly ; according to the statistical data, the area cultivated is only 132.5 hectares, of which $^{9}/_{10}$ belongs to the Trikkala estates, which are provided with very efficient industrial machinery for treating rice.

As for New Greece, it is in Epirus mostly and in Macedonia that rice is grown. In Epirus, the province of Paramythis produces 312 500 kg. per annum and that of Margation 875 000 kg. In Macedonia the chief rice-growing districts are Vodena (112 500 kg.), Karatzova (62 500 kg.) and Yannitza (25 000 kg.).

Sowing is carried out in spring, when the temperature rises, the ground being previously well worked, ploughed, levelled and cleared of weeds. Planks set on slight earthen dykes divide up the rice fields ; the arrangement of the channels ensures irrigation at will according to needs, and at the same time the ground is kept wholesome. It is usual to sow 125 to 187 kg. of seed per hectare, less in the ancient kingdom, more in Epirus and in Macedonia (New Greece). The seed is covered in by means of a plank drawn by animals over the flooded ground ; the soil is kept constantly moist. Hoeing is diligently pushed on, so as to ensure uniform and vigorous growth. Reaping is done by sickle, in July, August and even in September, according to the district and the variety cultivated. The yield is variable : on the average, from 12 500 to 15 625 kg. per hectare. In Thessaly, rice is followed by

a wheat, cotton or maize crop, and is grown again on the same ground after an interval of 3 or 4 years. The native varieties are distinguished as white rice (" aspro ") and red-brown rice (" kokino "). The former of these is the better in quality, earlier and less productive ; the latter is a better yielder but is late. Spanish and Italian varieties have given very good results in Thessaly.

According to analyses carried out at the State agricultural chemistry laboratory at Athens, the composition of Greek rice, compared with that of other foreign-grown rice (Bombay, Japan, Burma) is as follows : —

Substances estimated	Grown in Greece			Bombay rice	Japanese rice	Burma rice
	Spanish variety of rice	Italian variety of rice (Ostigliese)	Epirus rice			
Water.	13.02 %	12.71 %	12.34 %	13.00 %	14.48 %	13.20 %
Starch and sugar . .	77.23	76.61	76.30	77.63	70.83	74.10
Nitrogenous matter .	7.50	9.04	9.95	7.44	10.47	9.26
Fats	0.42	0.36	0.56	0.70	2.39	2.20
Cellulose	0.76	0.33	0.38	0.80	0.80	0.60
Ash.	1.07	0.95	0.47	1.23	0.91	0.70
	100.00	100.00	100.00	100.00	100.00	100.00

This table shows that the kinds of rice grown in Greece are relatively very rich in starchy matter and that, among them, the varieties of Spanish origin acclimatised to the country take the lead.

Greece, a small producer but a large consumer of rice, imports annually 5 000 000 to 5 625 000 kg. The following are details of imports from 1901 to 1912 into the old kingdom of Greece : —

1901	4 562 864 kg.
1910	5 509 929 »
1911	5 599 256 »
1912	5 397 150 »

Imported rice comes from various foreign countries and several varieties are found in trade. Compared with these the locally-grown product is of inferior quality, chiefly due to the lack of suitable industrial treatment (polishing, glazing, etc.), the only exception being Thessalian rice which is worked up in a first-class mill.

Though rice-growing in Greece is at present of so little importance, suitable conditions, especially in the new kingdom, open up for it a future not to be despised ; in fact, besides certain parts of the old kingdom, Epirus and Macedonia (Yannitza, Vodena Vally of Axios, Karatzova, etc.) contain suitable land and plentiful water supply.

Everything considered, the development of rice cultivation in Greece will follow the general agricultural progress of the country, particularly in the new kingdom. Hence the desired progress, which will soon provide Greek farmers with new resources and national economics with new re-

venue, is to be expected from the efforts and propaganda of the Greek government and, in its own special sphere from the Royal Agricultural Society.

199 – **A Study on Rice from the Cameroons.** — HEIM and HUSSON, in *Ministère des Colonies, Bulletin de l'Agence Generale des Colonies* (formerly *Bulletin de l'Office Colonial*) Year XII, No. 142, pp. 569-574. Paris-Melun, Oct., 1919.

The General Commissioner for France in the Cameroons sent to the " Office colonial ", through the efforts of M. ROUGET, Delegate for French Equatorial Africa, varieties of Cameroon rice, which were referred for analysis to the Colonial Products Study Department.

The study of 3 varieties of the rice gave the results summarised in the present note. Two varieties came from the sub-division of Yoko and are named " Yoko No. 1 " and " Yoko No. 2 " ; one variety was from the sub-division of Duala.

The authors give the detailed results of their analyses.

Of all cereals, rice is the one which contains most starch and least nitrogenous matter. With rice intended for starch-making, preference should be given to kinds especially rich in starch and, consequently, poor in nitrogen. This no longer holds good where the rice is for human or animal consumption, or for distilling or brewing. Hence the content of nitrogenous matter in particular should be taken into account. From this same point of view it should be noted that de-germing the grain is an operation which causes a diminution in the food value of the rice.

The varieties Yoko No. 1 and No. 2 are very rich in nitrogen. Their content is even higher than that indicated by BALLAND for Saigon rice, which was the richest in nitrogenous matter of the commercial sorts (decorticated grains) analysed by him. Yoko No. 1 contains 8.44 % nitrogen and Yoko No. 28.75 % whereas in Saigon varieties, according to BALLAND, the percentage varies from 6.90 to 8.38. Hence these two types are perfectly suitable for distilling and brewing.

The above statement applies equally to Duala rice ; the nitrogen content of the decorticated grain exceeds the maximum given by BALLAND, for Saigon rice : 9.31 % for the entire and 8.57 % for the decorticated grain. On comparing the content in nitrogenous matter of Duala whole rice with that of the varieties studied by BUSSY (decorticated rice), this content is seen to be lower than in certain Far-East varieties (mountain paddy of Rais in the Lang-Bian region in Annam, Java rice, " Carolina " variety, Phu-My crop, etc.), and higher than in other varieties of the same origin (South Annam (Nhatrang) red-grain paddy). It may be admitted that this rice is similar to the Far-East varieties in composition.

ARCH CROPS

200 – **" La Succulente ", a New Variety of Potato Suitable for the South of France.** — ZACHAREWICZ (Director of the Agricultural Services of Vaucluse), in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, T. V, No. 36, p. 927.Paris, Nov. 26 1919.

This paper describes experiments in growing in Vaucluse a new variety of potato, " La Succulente ", coming from the north of France.

Planting was carried out on March 15 on a clay loam soil moderately rich in nitrogen and potash but poor in phosphoric acid, cultivated to a depth of 40 cm. after the application of 30 000 kg. of manure per hectare. Growth was regular and the harvest, on June 24, gave 18 000 kg. per hectare, while the variety known as " Institut de Beauvais ", cropped under the same conditions yielded only 16 000 kg.

This new variety, considering its yield, the quality of its tubers and its earliness, will be of great value in the South of France.

201 – **Potato Growing in the United States.** — HOLMES, G. K., in *U. S. Department of Agriculture, Bulletin No.* 695, 24 pp. Washington, Oct. 16, 1918.

These data are for the use both of the public in general and of those specially interested in the production, trade and consumption of foodstuffs, and include many statistics on : — area under potatoes in the United States, production, imports, supplies, exports from one State of the Union to another, supplies for export abroad, consumption per inhabitant since 1849, summary for the period 1905-1914.

In the last period, which reflects pre-war conditions, 343 394 000 bushels of potatoes were harvested annually from 3451000 acres, with an average production of 97.0 bushels per acre, or 3.76 bushels per capita and 99.1 % of the supply. The average price paid at the farm for potatoes was 59.1 cents per bushel.

202 – **The Use of Johnson grass (*Sorghum halepenes*) in Italy.** — PANTANELLI, E., in *Le stazioni sperimentali agrarie italiane*, Vol. 52, No. 7-9, pp. 405-415, Bibliography of 25 works. Modena, 1919.

FORAGE-CROPS MEADOWS AND PASTURES

The " canarecchia " or " sorgagna " (Johnson grass) is a Gramineae that grows wild round the Mediterranean basin, from which it passes to Persia and on to India In Italy it is common on the alluvial soils of the lower valley of the Po, in the Valdarno, lower Tiber, etc. ; it is always present on sandy places generally and on light soils ; in vine growing districts it is common on sandy soils (e. g. in the Etna region in Sicily).

This plant does not appear to be cultivated in Europe, where it is even regarded as one of the worst kinds of weeds ; in fact, it is very difficult to root out, because it multiplies not only by seed but also from broken rhizomes. In India it is dried and used as fodder. In Egypt it is made use of when fodder is scarce, and in lower Venetia wheat stubble among which it is found is utilised for fattening, and searched ont by farm stock. Imported by chance into the United States, where it is called " Johnson Grass " this plant has become a real weed in the southern states, but, as it has been observed to provide good fodder and, thanks to its rhizomes, to resist the severest droughts and most rigorous winters, it has been grown for some years in the semi-arid zone of the Union, from Oregon to the Gulf of Mexico, as a summer fodder plant. Mr. SCUDDER has got from it, without irrigation, in Oregon, 25 quintals of hay per hectare. With the help of irrigation, in regions where the rainfall amounts to 400 mm. per annum, up to 80 quintals of hay have been obtained per hectare from it. In the United States, Johnson grass has also been found useful as a wind break to shelter the most

delicate of the shrub crops. At the beet cultivation experiment station of Rovigo, M. Munerati planted hedges of the grass round plots of selected beet in order to prevent cross-pollination among them.

This sorghum has been imported by chance also into Australia, where it has thriven to such an extent, as to be one of the utilisable wild fodder plants.

With a view to trying the use of this plant also in Italy, where it is a wild native, the author grew experimental crops of it near Rome. As the seeds are of low germinating capacity, although maintaining their vitality for several years, he multiplied the crop from pieces of rhizomes, 5 to 10 cm. long, planted on the March 20, 1918, at a depth of 5 cm. and 5 cm. apart, in lines spaced at 30 cm., and in a mellow but very poor soil hoed on the surface and not manured. No subsequent cultivation was given. The year was a very dry one. At the flowering period in September, 7330 kg. of grass (65 % water) was harvested, which gave 2950 kg. of hay (15 % water) having the following composition: Leaves, 32 %; stalks, 58 %; panicles, 10 %; and with the following chemical composition: Water 15, %; raw protein, 6,58 %; oils and fats (raw), 1,25 %; non-nitrogenous extract, 27.24 %; cellulose, 44.80 %; ash, 5.13 %.

Similar trials made in 1919 gave like results,

Conclusions. — Cannarecchia, although it should be kept down in many cases, because it spreads everywhere, is utilisable for several agricultural and industrial purposes. Easily grown on poor soils, even barren and dry ones, it is very resistant to drought. As it continues growing during the dry season, in the most arid places it is capable of providing, at the time of the greatest scarcity of green fodder, about 75 quintals of grass per hectare or 27 quintals of hay not much inferior in quality to that of fodder sorghum. The rhizomes are still more useful than the hay; under cultivation, a yield of 200 quintals has been obtained per hectare. They contain as much as 27 % starch and 13 % sugar (mostly saccharose), but on the other hand they contain little fibre, and hence make good feed.

From the rhizome, besides 25 % starch (air dried) there can be got 25 % sugar syrup (50 % water) which may be used either as human food or as a source of 7 % by volume of ethyl alcohol (95 %). If the rhizome is used only for making alcohol, 18 to 21 % by volume of 95 % alcohol is obtained from it.

In every way Johnson grass deserves to be included among the useful plants, especially in regions where there is a long period of drought in summer.

FIBRE CROPS

203 – **The Cultivation of Fibre Plants in Indo-China: *Agave Cantala*** (1). — I. Chevalier, Aug., in *Bulletin Agricole de l'Institut Scientifique de Saïgon*, Year I, No. 9, pp. 266-270. Saïgon, Sept., 1919. — II. Vernet, G., *Ibid.*, pp. 270-276.

The provisioning of Europe in fibre other than cotton and wool (i. e. hemp, flax, jute, henequen (2), sisal) is becoming more and more difficult.

(1) The authors designate under this name the species called *Agave Cantula* Roxb. in the *Index Kewensis*. (*Ed.*)

(2) Agave fibre, under the names of "Henequen", "Chanvre de Sisal", "Sisal hemp", "Ixtle „, and "Tampico", has made Yucatan, formerly disowned and considered useless for agri-

Some countries, like Russia, which supplied large quantities of flax, are no longer exporters. The unsettled state of Mexico during the last few years has reduced the production of henequen, and the agave plantations of German East Africa which yielded in 1912-13 about 20 000 francs, worth of fibre, seem to be non-existent since they were abandoned during the war.

The time is therefore favourable for starting certain textile fibre crops in the French colonies.

From time immemorial in Indo-China, the Annamese have grown jute and ramie ; also the mountain population of Tonkin and North Annam grow some hemp, but the yield of fibre has always been very small.

Since 1878, attempts at the cultivation of ramie, crotalaria and *Aeschynomene cannabina* have been made under the direction of the botanist PIERRE near Saïgon. Later on, the trials were continued at Tonkin. They were concerned chiefly with jute, the textile banana tree or "abaca" agave, *Hibiscus*, and the crotalaria. At the time of the Colonial Agriculture Congress in 1918, M. HAUTEFEUILLE made public the results he had obtained (1), but they were not very conclusive.

In 1918-19, the experiments were renewed at various places in Indo-China, with the following plants : 1) flax, at Tonkin ; 2) hemp, at Laos : 3) jute, at Tonkin and in Cochin China ; 4) agaves, in South Annam. The two notes summarised give the first results of the studies undertaken on the last of the above four crops, the agaves, especially *Agave Cantula* Roxb (2).

In the south of Annam, between the sea and the southern spurs of the Annam Cordilleras, there is a belt of 2000 to 3000 square kilometres lying in the provinces of Phanrang and Phanthiet, in which the desert characteristic is excessively remarkable.

This belt is very easy of access, being traversed along its whole extent by the Saigon-Nhatrang railway and including the port of Bangoï. The country is sandy, dry and arid, and certainly in Indo-China there is no district more suitable for the cultivation of the agave.

The *Agave Cantala* (the " Maguey " of the Philippines), doubtless of Mexican origin, has for long been considered to be the *Agave americana*, but latterly several American botanists have shown it to differ from the latter in some important respects. The name applied to it today was

---

culture, a prosperous country (L. HAUTEFEUILLE, *L'Agave textile au Tonkin*, Congrès d'Agriculture coloniale, Série Hanoï, No. 3, Hanoï-Haïphong, 1918) (*Ed.*)

(1) See *R.* Dec. 1918, Nos. 1387 and 1358. (*Ed.*)

(2) M. L. HAUTEFEUILLE, in his paper entitled *L'Agave textile au Tonkin*, indicates the following two varieties of *Agave Cantala* : — 1) *A. Cantala*, commonly miscalled *vivipara.* ; 2) *A. Cantala variegata.* very ornamental and remarkable for the white striping on every leaf. According to this author the following are the species and varieties eperimented with at Tonkin : —(1) *A. rigida sisalana* ; 2) *A. rigida elongata* ; 3) *A. Cantala* ; 4) *A. Cantala variegata* ; 5) Agave not strictly determined, a false sisal called *lurida* in some cases and *decipiens* in most ; 6) *A. americana* : 7) *Fourcroya* (= *Furcraea*) *gigantea* ; 8) *Zapupe*, sent by the Colonial Gardens of Nogent-sur-Marne on account of remarkable qualities not yet defined. (*Ed.*)

created by the English botanist ROXBURGH for the form of it which is naturalised in British India and commonly grown, according to STEWART, in the Punjab to make hedges.

The *Agave Cantala*, although certainly of American origin, has not yet been observed in its native land, and it is known to this day only on the coasts of tropical Asia, in the Malay archipelago and in the Philippines, where it was introduced by the Spaniards at an early period. According to E. D. MERRILL, it is an ornamental plant extensively cultivated in several provinces of the Philippines for its fibre. HAUTEFEUILLE states this species also, and not the true sisal (*A. rigida* Mil.), in grown in Java for the production of sisal fibre fou export (about 4000 tons per annum).

E. D. MERRILL says that *Agave Cantula* Roxb. is synonymous with *Furcraea cantula* Haworth = *Agave Rumphii* Hassk. This would be also the *Agave americana* of RUMPHIUS (not of LINNAEUS), wrongly identified by LINNAEUS with his *Agave vivipara*. The latter species in any case remains a mystery, and it may be that this is the plant in question.

In short this species was brought from America by the Spaniards long ago, is known only in Indo-Malaya, where it is cultivated and naturalised. It is also found in abundance all along the coast of South Annam, and is sometimes planted on graves and around pagodas in the rest of Indo-China. Its introduction seems to date very far back, although LOUREIRO did not mention it in 1790 in his Flora.

In the arid belt referred to, *A. Cantula* is already very widespread. It multiplies by suckers, bulbils and seed. On dunes it appears to be a good fixing agent for sand; from this year onwards the Annam Forest Department, under the direction of M. H GUIBIER is taking up the breeding of it It is a plant which will serve for industrial uses, and the investigations carried out by M. VERNET will soon provide reliable information as to its value and the yields to be expected when it is methodically cultivated.

II. — Being struck by the growth of sisal in the region of Tourcham, in the province of Phanrang, M. CHEVALIER, Director of the Scientific Institute, requested the author to look into the question, to determine the fibre content of the leaves of these Amaryllidaceale and to investigate the possible prospects of their cultivation as textile plants.

BOTANICAL ORIGIN. — The agave is known in Cochin China and Annam by the names " Thom-tào " or " Gai-tào ", which mean Chinese Pineapple or Chinese Ramie.

This is not an indigenous species and, in spite of its name, this plant is not a native of China, but, according to the results of M. CHEVALIER, it is the *A. Cantula* Roxb. which, like all the agaves, is a native of America.

HABITAT. — A very superficial review of the matter might give rise to the belief that the agave in the Tourcham district grows naturally in the bush, without any attention whatever, and that its cultivation, on this account, may be limited to the establishment of a plantation, which need only be left to itself for a certain length of time before the owner, returning a few years later, can profit by it. Such a procedure would be a grave

mistake, and one which has in fact already given some planters a set-back which should not be repeated.

On closer examination it is found that the agave is planted by the natives in lines, on the borders of the fields as live hedges. Sometimes these hedges, when left without attention, are gradually invaded by wild shrubs ; the brushwood then slowly takes the place of the agave plants, and the whole often has the appearance of wild-growing vegetation.

Moreover, although the agave is not an exacting plant, it would be a mistake to think it acquires the luxuriant growth found in the provinces of Phanrang and Nhatrang entirely by coming up at random in the sand. In practice, as these plants form living fences round the fields, the operations of cultivation, ploughing and harrowing are the means of benefiting the plants round the border. In addition, all the plant waste that is dragged to the outside by the harrows is thrown beside the fence, where it rots and so little by little forms a top soil which is not without effect on the growth of the plants whose roots it covers. In the districts of Ninh-chu and Nhatrang, where agaves are planted along the roads, they receive the sweepings and various kinds of animal refuse. Though this plant is not exacting, since it will grow and even spread in extremely poor ground, it is nevertheless very responsive to any help in fertilising material and to all cultural operations.

The author gives two analyses of soil samples taken from the roots of the best-developed agaves in the Tourcham and Ninh-chu districts. The results of these analyses show that the soil is very sandy, containing a little lime and organic matter of which a certain proportion has already become humus. Its content of nitrogen and fertilising mineral matter is very low, but still appreciable.

Further, analyses of agave leaves show a plant whose vegetative parts above ground contain only from 15.6 to 17.8 % dry matter and 84.4 to 81.2 % water. The leaves are very poor in nitrogen, containing only 1.19 % in the dry matter.

An investigation of the mineral contents of the dry matter gave the results shown below :—

Silica	0.280 %
Phosphoric acid	0.303
Potash	1.120
Lime	3.710
Magnesia	1.320
Peroxide of iron and aluminia	0.320
Soda, carbonic acid and undetermined substances	3.087
Total ash	**10.140** %

One of the mineral elements to which attention should be drawn is the lime, which enters into the constitution even of the agave textile fibres. The mean weight of the leaves growing under good conditions being about 1 kg., it is sufficient to multiply the preceding figures by 10 in order to find out what a leaf will remove from the soil.

As each plant of *A. Cantala* has 80 to 90 leaves, it is evident that a regular plantation, in which shoots are entangled among the original plants, eventually takes up a fairly large quantity of fertilising material which will be regularly removed from the soil by continuous cropping.

The growth of agaves, with small plants from the suckers gradually increasing in number, suggests the establishment of a regular plantation, in rows 4 to 5 metres apart, with intervals of 1 metre between the plants in the rows. The intervening spaces could thus be easily cultivated and manured, and might even serve to grow improving catch crops, such as groundnuts, beans and various legumes, of which the leaves would be regularly left on the soil ; likewise small carts could pass up and down the rows when harvesting the leaves.

Growth. — Studies on the growth of agave have shown that under good growing conditions these textile plants in Indo-China can be turned to use after 3 years at most, counting from the time they are planted ont.

Fibre content of the leaves. — De-fibring was done by hand. A first operation, hammering the leaves with a wooden mallet, gave, after drying, 2.86 to 4.75 % of fibre. Complete cleaning by hand, fibre by fibre, made a difference in weight of 30.9 %.

The yield of the leaves in fibre dried in the air and perfectly cleaned by hand varied from 1.9 to 3.8 % with a mean of 2.5 %.

Agave fibre. — The bundles of fibre are thicker at the base of the leaves than at the point, and are not round but more or less flattened. Microscopic examination shows that they are made up of a large number of elementary spindle-shaped fibres, with smooth walls, united to each other, 2 to 2.5 mm. in length, of irregular polygonal section, of 0.03 to 0.06 mm. in outside diameter and 0.02 to 0.03 mm. in inside diameter. Hence the resistance or breaking strain of such bundles varies according to the part tested. By ordinary mechanical means it will never be possible to extract the fibre in all its length. i. e., totally ; in fact, it breaks near the end. According to extraction processes and apparatus used, the yields of textile fibre are suscep tible of fairly wide variations.

Conclusions. — The results obtained are encouraging for the future, and if agave fibre is not of very great intrinsic value, the quantity that can be obtained on moderately fertile land will make up for this inferiority.

It has not yet been determined how much can be produced in leaves annually from a hectare regularly planted and well maintained. Trials are to be carried out at the experiment station of Giarai (1) and others on much poorer soils at Bangoi and Dongmé, so that the question may be expected to be resolved soon.

204 - **Broom (*Spartium junceum*) and its Uses in Calabria, Italy.** — Casella, L.A., in *L'Italia agricola*, Year LVI, pp. 374-380, 1 fig. Piacenza, Dec. 15, 1919.

The broom plant is of great service in fixing land, as well as enriching it in nitrogen, being a leguminous plant. It provides sheep and goats with a pasture not to be despised, and as these animals are especially fond

(1) On the subject of the agricultural station at Giarai, see *R*, Oct. 1918, No. 1068. (*Ed.*)

of the young shoots, in order that they may not damage too much and even destroy broom lands, they should be put to graze there only after the shoots have hardened a little, in autumn and winter.

In domestic economy, broom is put to various uses small faggots are made to light fires, large sweeping-brooms, temporary roofs for huts, bands for plants fixed to props, bushes for silk worms, etc. In Calabria, when silk-worm eggs were produced, the branches, bound together in the form of small screens, served here and there for the female moths to lay their eggs on, a purpose to which they were extremely well adapted, because later on the eggs could be detached very easily, after immersion for some time in water where they were let float on the surfacce, passing them between the thumb and first finger ; by this means the eggs were at the same time washed and cleaned of unfertile specimens which float.

Broom is of limited heating capacity but gives a long live flame, which makes it useful for lighting fires or renewing them, and is of good service where flames are wanted to lap the heated surface all over, as in ovens.

For firewood, broom is cut every 3 years, towards the end of autumn, and grazing is prohibited for a year after cutting. It is a good honey-producing plant, and its seeds could be fed to poultry and pigeons.

The part of greatest utility is the bark, from which a textile fibre can be extracted. The latter is prepared, spun and woven, as a home industry in many parts of Calabria, especially the province of Cosenza. Broom-fibre fabrics are made also in some parts of Basilicata, in Tuscany (where they are called "panni ginestrini"), in the south of France and in Spain. These goods are noted for their extreme lightness ; from 11 kg. of flax as much as 60 metres of cloth may be obtained, while from only 7 kg. of broom fibre it is possible to make the same length.

These fibres are used also to make ropes and paper, which are likewise distinguished for their great lightness.

The broom-cloth industry ("panni ginestrini") includes the following operations : cutting of the branches ; boiling of same ; maceration of the boiled branches ; stripping off the bark ; beating ; swingling ; carding ; spinning of the fibre ; weaving bleaching ; of the cloth.

The branches are cut during July and August, only those of 2 years' growth being taken. They are boiled in open boilers for 4 to 8 hours, the bundles being turned over in the boiler at least once, and the operation is finished when the green colour disappears from the branches. This is a delicate process, because, if insufficiently boiled, the bark does not come off well and the fibre is not white, and if boiled too much the fibre loses in tenacity. Maceration is done in running water and lasts from 3 to 8 days. The bark is stripped by hand. Beating is done with a wooden club on a fairly even-surfaced stone, near the same stream where the maceration was done ; the operation is divided into two stages, with a rinsing in between, and requires rapid working and good weather because in the same day the fibre after being twice beaten and rinsed, must be exposed to the sun to be half dried, otherwise it darkens and loses in value. At this stage of preparation the fibre can be used for rope making. A further stage of preparation consists

in swingling, which separates the longest and finest fibres from the shorter and coarser, that is, the fibre ("manna") from the tow ("stoppa"). Both of these can be spun and woven, the former giving moderately fine cloth, and the latter coarse stuff (for bags, wrappings, etc.). Ordinary machine carding separates the fibre into high grade fibre ("cuor della manna") and tow ("stoppa") ; the former, when spun finely, can give very fine cloth of great beauty. Spinning and weaving are done by hand, with the old-fashioned household spindle. The cloth is bleached on the grass, being wetted and dried alternately.

Broom cloth is remarkable for its durable qualities ; it is said to last for centuries.

Several times attempts have been made to transform the Calabrian home cloth industry into a big mechanical one, but without success. More serious attempts were made during the war. In the Rogliano country (province of Cosenza) a workshop was set up for the mechanical working-up of the broom, but it cannot be said that the scheme has passed the experimental stage. It appears that machine-extracted fibre loses greatly in length and strength, so much so that it is utilisable only as raw material for paper making.

PLANTS YIELDING OILS, DYES, TANNINS, ETC.

205 – **Linseed: the Influence of Geographic Origin and Variety on the Composition of the Oil; Investigations in the United States.** — RABACK, F., in *U. S. Department of Agriculture Bulletin No.* 655. 16 pp. Washington, april 20, 1918.

For 2 consecutive years 4 varieties of selected flax — C. I. (Cereal Investigations) No. 3, Damont (North Dakota 1215) — C. I. No. 2, Primost (Minnesota No. 25) — C. I. No. 13 (North Dakota Resistant No. 114) — C. I. No. 19 (Russian) — were grown in districts of Montana, North Dakota, Wyoming, South Dakota and Oregon differing greatly in climatic and soil conditions. Oil was extracted from the seeds thus grown and a determination made of the colour, specific gravity, refraction, acidity, saponification and iodine indices, and drying properties.

To determine the yield of oil of the seed, extracting was done with ether, and to obtain samples for finding the physical and chemical constants, cold pressure was used.

The following conclusions, shown in a series of tables, were reached from the results of the analyses :

Varieties of linseed which have different agronomic properties show also different physical and chemical properties in their oils. These properties keep up in a very marked manner from one year to another. The yield of oil changes both with variety and with locality. The specific gravity, refraction index and colour cannot be so easily correlated with the variety and locality. A direct relationship appears to exist between the drying properties of the soils on one hand and the specific gravity, acid index, iodine index and colour on the other hand. Oils having at the same time a strong acidity and high specific gravity, and also a relatively high iodine index, dry more rapidly, forming a solid film. Oils of lighter colour invariably dry more rapidly.

206 - **The Effects of Irrigation on Olive Production, in Tunisia.** — MARÈS, R., in *Revue de Viticulture*, Year XXIV, Vol. LI, No. 1315, pp. 168-171. Paris, Sept. 11, 1919.

Few crops in North Africa cost more for irrigation water than tree crops. No other crops give more constant and lucrative yields, for little capital outlay, in the countries round the Mediterranean basin with a climate too dry and too irregular to allow of cereal growing. Moreover, in those parts where the existing population has acquired a certain density in consequence of peaceful times or prolonged security first fruit trees were planted and then it was endeavoured to increase their yield by bringing under control springs, rivers, and subsoil and rain water.

Algerian vine growers have given a striking example in not hesitating to bore as deep as 40 metres in search of water to irrigate their vineyards.

Under these conditions the water costs about 0.10 fr. per cubic metre, a price which is equivalent to a sum of 3000 fr. a year for 1 litre of water per second continually. Almost equally costly plant is set up to water citrus plantations where the rainfall is deficient.

In the Sahara, however, where dates are grown, water reaches a value unheard of in all other places. It has been calculated that in the Biskra oasis a litre per second comes to cost the user a net sum which may amount to 10 000 francs. This is far beyond the value of the irrigation water used for fodder plant or cereal production in temperate countries, where 50 francs appears to be the maximum rate.

The olive, which is usually regarded as a tree of arid land, gives the water used for it a very high value, and being the fruit tree par excellence of Tunisia, the country of place, sobrety and thrift, it is there more frequently irrigated than is generally believed.

In Tunisia, the advantages of olive irrigation by flood water have been more appeciated than anywhere else, although it has been carried out with very precarious supplies of water.

Near the desert limit, north of Gabes, some olive groves have been laid out so that they are flooded every time there is flood water, and their yields testify to the benefit of these irregular floodings in this arid district.

In the Tunisian Sahel, all running water is diverted with great care into the olive plantations. The hill tops are provided with rain-water tanks and the water is distributed to the groves spread over small areas on the hillsides and in the valleys.

In the north of the Regency, the fine, olive trees of Nebur, Kef and Tebursuk show the benefits of irrigation by their high and regular yields.

In an experiment made at Grombalia (by M. E. DUMONT), according to whether the olives were watered or not, the yield per tree varied from 180 litres of olives weighing 125 kg., capable of giving 19 kg. of oil (worth 38 francs, at 2 fr. per litre), to 20 litres weighing 15 kg. and equivalent to 2.5 kg. of oil (worth 5 francs).

Another example of the effects of irrigation on olives is furnished by the school farm of the Israelite Alliance of Djedeida.

This farm owns 7300 young olive trees, of which 2000 began to be watered in 1900-1901, while the other 5300 were not watered. The following

table gives a summary of the results obtained in this olive plantation b irrigation :—

Years	Yield from	
	2000 trees watered	3500 trees not watered
1900–1901	45 000 kg.	45 000 kg.
1901–1902	23 000 »	26 000 »
1902–1903	10 000 »	2 000 »
Totals . . .	**78 000** kg.	**73 000** kg.

Hence the watered trees gave an average annual yield of 13 kg. pe tree, whereas those not watered did not yield over 4.6 kg.

In view of the high prices prevailing for olive oil, the few example cited above show that watering the olive trees should never be neglecte at flowering time and in autumn wherever it is economically possibl

RUBBER, GUM AND RESIN PLANTS

207 – **Gum Tragancath in Mesopotamia.** — *The Board of Trade Journal*, Vol. CIII, No. 119 pp. 623-624. London, 1919.

The most valuable gums of Mesopotamia are the gum tragacanth which are produced by tapping small shrubs. These shrubs appear to gro all over the mountains of Southern Persia, and from there through the e tire mountainous region which runs North-West along the frontiers of M sopotamia, comprising auch areas as Northern Arabistan, Luristan, Pus i-Kut Country, and Kirdistan. The most important collecting cent for Baghdad is Suleimanaya, the capital of the Suleimanaya district Kurdistan, situated about 180 miles to North-East of Baghdad. In th area there is a regular trade in this gum for the Baghdad market.

The method of tapping the bushes is as follows :— The Kurds firs burn all the leaves off the bushes, then expose the roots, cut incisions i the roots, and leave them for a week or so ; they then return and collect th gum which exudes from the roots. The first tapping produces white gu of the best quality, second and subsequent tappings, gums of yellow c lours and inferior quality. Excessive tappings weaken and may kill th bushes if done to excess.

The Kurds bring the gum to Suleimanaya, where it is bought by loc merchants, who export it to Baghdad on pack transport in caravans, an sell to Baghdad merchants. These merchants export to England and oth foreign countries. The local Customs authorities levy a 12 ½ per cen tax on the market value in Suleimanaya.

The northern mountainous Kurdish country in the Musul Vilayet a mass of mountains and valleys. The mountains are covered with scru evergreen oak forest, and the higher hills and plateaux are full of thes gum bushes (called, " guweyni " or " guni " in Kurdish). In spite of th prevalence of these bushes, no organised trade appears to exist, althoug Persian merchants are said to have come down off and on in the past t

exploit these gums. The distance from Mosul town to this gum-bearing country is from 50 to 100 miles. All transport at present is on pack animals, but three unmetalled roads up to the hill country have been constructed. The country is at present wild and unsettled, but with the introduction of law and order, the opening up of the country by means of roads and the construction of a railway to Mosul, the exploitation of gums in this country should be possible in the near future. The export from Bagdad in 1887 was 641 250 kg. (= 130 tons), and in 1890 it had decreased to 39 tons.

A second kind of gum is produced from a large tree, which grows throughout the part of Kurdistan. The tree is known as " Buttom " by the Arabs and " Gkraswan " by the Kurds. It grows to a great size, 50 feet high and up to 8 feet in girth. It is found scattered throughout the valleys only, especially near the villages in the forests. The tree produces edible fruits (sold for food and for extraction of oil in Mosul, Baghdad, and all other local markets of any size in Northern Mesopotamia), and also a gum, called " elk " in Arabic. The method of tapping this elk gum is by making long incisions in the trunks of the trees, and placing some receptable underneath to catch the exuding gum.

A regular trade in this gum exists in the Suleimanaya district of Kurdistan, but there is no trade whatever in that part of Kurdistan which falls in the Mosul Vilayet, although " Button " trees abound in the valleys of that country. The bulk of " elk " gum is exported direct from the Suleimanaya district by caravan to Aleppo, where it is used for sizing cloth. Some portion comes to Baghdad. There is no foreign export of this gum from Baghdad ; it is all used up locally for sizing cloth, local medicines, as a local chewing gum, and in the manufacture of arrack liquor from dates. There is no doubt that very large amounts of this gum could be collected from the areas mentioned, under conditions similar to those already described for the gum tragacanth.

208 – **Sugar-beet Growing Experiments in Oran (Algeria).** — VERMEIL, P. (Director of the General Agricultural Department at Oran), in *Revue de l'Afrique du Nord*, Year XVII, No. 18, pp. 304-310. Algiers, Nov. 28, 1919. SUGAR CROP

As the sugar question is of such pressing importance at the present time, it is good that Algeria should set to and produce sugar for her own consumption, seeing the warm climate is so favourable to beet growing.

Oran consumes 12 000 to 13 000 quintals of sugar per month. It is doubtful whether it can produce so much, but it can produce a good part of this quantity. The climate would certainly allow, by intelligent and judicious cultivation, of eventually having richer beets, with a greater weight of roots per hectare and consequently a higher yield of sugar from an equal area than in France.

The economic side of the sugar industry in Algeria has not yet been definitely settled. The author studies the sugar question only from the technical point of view.

The area devoted to beet growing will always be limited in Oran owing to the lack of water. The best-situated districts will be those in which there

are barrages, rivers with water in summer; such are the Felat, Sig, Perregaux, Relizane districts, then Bel-Abbes, Ain-Temouchent, where the soils are rich and cool in summer, and perhaps also Saïda which will supply sugar in the south.

The indispensable condition for enabling a sugar factory to be set up is to be able to dispose of 1200 to 1500 hectares of land, within a radius of 5 to 6 kilometres at most, adapted to beet growing (in practice, a factory ought to work at least 120 000 quintals of beet during the season; if the yield is 300 quintals per hectare on the average, 400 hectares will be required per annum, or 1200 to 1500 hectares of land suitable for this crop, when it comes into the rotation).

The quality of the soil and water plays an important part, as the richer the juice is in salts the lower is the yield of sugar. In this respect the Tell district in Oran is badly situated, the irrigation water and much of the cropped land being rich in chlorides and in carbonate of lime. Mascara, Saïda and Fiaret offer much purer springs and soils in this respect.

The author gives an account of the experiments he has carried out on beet growing. Six varieties from the firm of VILMORIN were tried (4 sugar and 2 half-sugar), sowing being done in spring, as the seed arrived too late for autumn sowing, at the following places:— experimental plots at Oran, on the Habra estate, at Trois-Marabouts, on M. NORREN's property, and at Temouchent.

Table I sums up the results obtained.

TABLE I. — *Results of beet-growing experiments in Oran.*

Varieties	Weight of roots per hectare in kg.	Sugar content %				Yield of sugar per hectare in kg.				Observations
		Habra estates		Oran	Témouchent	Habra estate		Oran	Témouchent	
		Unirrigated	Irrigated	Irrigated	Irrigated	Unirrigated	Irrigate	Irrigated	Irrigated	
1) Improved white sugar beet, Vilmorin *A* . . .	38 540	14.00	9.60	11.80	12.40	5 400	3 700	4 550	4 800	For want of more exact data, the weight of roots per hectare was taken to be the same as at the experimental plots at Oran.
2) Improved white sugar beet, Vilmorin *B* . . .	50 130	13.90	12.00	10.00	13.00	6 970	6 015	5 013	6 520	
3) White sugar beet Française riche	46 340	13.20	8.00	10.00	13.60	6 120	3 710	4 634	6 305	
4) Improved white sugar beet, Klein Wanzleben	40 500	14.80	10.80	8.40	12.00	6 000	4 375	3 405	4 860	
5) Distillery beet, green neck	55 120	10.00	7.90	8.00	7.20	5 512	4 355	4 410	3 880	
6) Pink distillery beet, green neck	50 200	12.00	8.00	3.20	2.60	6 025	4 016	1 606	1 305	

The maximum richness in sugar was got on the Habra estates with unirrigated beet of the variety Klein Wanzleben. The least rich beet was the irrigated crop on the same estates, with the white variety Française Riche.

The highest yield of sugar per hectare was given by the improved white sugar beet Vilmorin B on the Habra estates (6 970 kg.) ; the lowest by Klein Wanzleben, at the experimental plots at Oran (3 405 kg.)

The sugar content is about the same as in France, where it varies between 12 and 14 per cent. On the other hand, in France the yield of sugar per hectare scarcely exceeds 3500 to 4000 kg. because the yield of roots is lower than that obtained in Oran.

The experiments seem to indicate that large roots are not much richer in sugar than small ones ; some are of exactly the same composition. Beets pulled on July 20 are appeciably richer than those pulled on June 20. The roots could be kept without inconvenience in the ground up to the middle of August or even till the end of September in the cool soil of Temouchent. By this means the rainy season could be awaited before starting the factories, which would then have pure water for the diffusion process. Besides the roots are difficult to pull before the rains, on hard strong soils, and many of them are broken.

Cultivation trials made on the estate of M. PANSARD at Montgolfier with 4 varieties sown in spring and pulled at the end of October, gave the results shown in Table II, which confirm the author's conclusion regarding late pulling.

TABLE II. — *Results of experiments at Montgolfier on M.* PANSARD'S *estate.*

Names of the varieties from M. PANSARD'S estate	Weight of roots per hectare	Sugar content	Yield of sugar per hectare
1) White, sugar, Vilmorin *A*	40 125 kg.	14.2 %	5 697 kg.
2) White, sugar, Vilmorin *B*	33 850	12.	5 062
3) White, sugar, Française Riche Fouquier.	39 800	11.	4 378
4) White, sugar, Wanzleben	33 600	16.4	5 510

Lastly, exposure of the pulled roots to the sun quickly gives a greater concentration of sugar in the beets. Only the water in them evaporates, and the roots gradually dry After 18 to 20 days they begin to get wrinkled and have lost 35 to 40 per cent. of their weight. At this time the sugar content rapidly increases and may easily reach 18 to 20 per cent. Hence the sun might bring about a real first concentration of the juice, and the beets could be worked only when the saccharimeter indicated a minimum content of 15 to 16 % of sugar.

The Habra experiment station will continue the author's researches, with all necessary precautions and care.

STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS

209 – **Tea Growing in the Dutch East Indies** (1). — BERNARD, C. (Director of the Tea experiment station at Buitenzorg, Java), in *Revue Générale des Sciences*, Year XX, Nos. 17-18, pp. 516-521, 3 fig. Paris, Sept. 15-30, 1919.

In statistics dealing with the growing of and world's trade in tea, in most cases considerable space is given to British India and Ceylon, China and Japan, but Java either is not mentioned or is only occasionally indicated amongst the " other producing countries ". The author finds no justification for this, considering the importance acquired by tea production and the great progress made by it, within a comparatively short space of time in the Dutch colony.

The quantities of tea exported in 1915 reached the following figures :—

British India	over	154	million kg.
Ceylon	about	97	» »
China	over	177	» »

In that year, Java produced 46 million kg. whereas in 1903, for example, her exports of tea came to only 10 million kg. (in 1910, a little over 18 million, and in 1914, about 32 million). In 1915 there were in Java nearly 30 plantations, with a total area of about 75 000 hectares.

During the last few years, as land for tea growing has become scarcer there, it has become necessary to look to other islands of the Dutch Indies, Sumatra in particular, where large stretches of land are still available. At the end of 1915 there were already over 20 plantations in Sumatra, covering some 6000 hectares.

Plantations are generally of 350 to 700 hectares in extent, and the production in most cases is from 300 to 1500 kg. per hectare. These figures, it will be seen, stand comparison with the results obtained in Ceylon and British India, where tea growing is carried out on an intensive scale, backed by powerful financial assistance (while in China and in Japan it is in the hands of the small cultivator). It should be added also that in Java the native population grows tea as well, and that the importance of the cultivation is in no wise negligible ; the tea gardens are of 1 to 10 hectares and over in extent (sometimes up to 20 hectares and over) and in 1919 covered a total area of nearly 20 000 hectares, yielding over 16 million pounds of tea, which means to the native population a gross gain of 260 000 Dutch *florins* (7 488 000 francs *at par*).

Java tea is of very good quality, as shown by the prices obtained on the London and Amsterdam markets ; in the last few years many consignments have fetched 1 shilling and above per pound at London.

The tea plant grows best in a warm moist climate. During the whole growing period, (and, consequently, producing period) it needs constant rains alternating with short dry periods. Bright mornings followed by

(1) As the Dutch East Indies belong to the Middle East, it may be useful, to complete the tea question in this vast zone, to refer the reader to what has been published on tea in Indo-China (the subject of tea in British India and Ceylon being well known) :— see *R.*, Nov., 1918, No. 1243, *R.*, April, 1919, No. 467 and *R.*, June, 1919, No. 601. (*Ed.*)

wet afternoons constitute very favourable conditions for the tea plant. This means that districts suited for tea growing are on the whole fairly limited ; in Java these conditions appear best for the crop in the western part of the island, but it has been possible, often with some success, to establish tea plantations also on the mountain slopes of the centre and east.

The tea plant is not very exacting with regard to soil ; recent volcanic soils, however, rich in humus and containing a sufficient proportion of sand and clay appear to suit it best.

As to altitude, it has long been admitted that between 600 and 1000 metres is best for tea planting, but plantations established in the last decades up to 1800 metres and above have given excellent results, both as regards the quantity and quality of the product.

At present only good types of Assam tea are planted. The old China tea gardens have been mostly cleared out and replanted with broad-leaf types. The vigour of the plants, and the size and colour of the leaves differ according to the variety adopted. Seed gardens are being more and more established in Java where the plants have undergone strict selection and produce descendants of a pure type possessing the properties required for a given plantation, but the production of the existing seed gardens in Java is not sufficient to meet the ever-growing demand for the crop, and large quantities of seed have to be imported every year from British India.

The seeds are generally sown in nurseries and put in about 15 cm. apart at a depth of 2-3 cm. In some districts, if climatic conditions are suitable, the seed may be sown directly in the cleared gardens. In places where prolonged periods of drought are to be feared, the nurseries are covered over with temporary shades to protect the young plants against the heat of the sun.

When the seedlings in the nurseries are of one or two year's growth, they are transplanted to the gardens, which have been previously cleared out (trees removed and soil cleaned of weeds and ploughed). The lines have been determined in advance, following the level on the slopes and leaving a space of about 120 cm. between them, and it is along these horizontal lines that the young plants are put at distances of 90 cm.

Cultivating and weeding must be regularly done ; a system of terraces, drains, and ditches to hold the water and so prevent erosion is established ; the manures considered necessary are applied ; and leguminous crops are planted for green manure. In short, all the necessary steps are taken for the judicious working of an intensive cropping system.

Tea plants in Java are attacked by certain enemies and diseases. The worst trouble is caused by an insect (*Helopeltis* sp.) which by piercing the young leaves totally destroys them ; plants thus affected often fall prey to numerous parasites of animal or vegetable origin ; an orange coloured mite (*Brevipalpus* sp.), though on the whole less injurious than the *Helopeltis*, nevertheless in some districts, especially on high plantations, causes fairly serious damage, of more importance than that due in British India to "red spider" (*Tetranychus* sp.), which in Java is of little account. The roots are often attacked by fungi of different species, which grow on all

kinds of decomposing vegetable refuse and pass from there to the tea plant roots. Plants thus damaged die off and the disease spreads to neighbouring bushes. Caterpillars, plant lice and various fungi often attack the leaves of tea plants ; against these, early and energetic measures must be taken to avoid serious damage being done.

When the plants are 2 or 3 years old they are pruned for the first time, and this operation is repeated every 18-24 months according to circumstances. It is mostly owing to judicious pruning that the bushes come to have their characteristic shape :— single stem, branched more or less near the ground, with plenty of small branches which at a height of 1 or 1 ½ metres form a flat or convex surface of large diameter from which the twigs will spring which will provide the leaves to be picked.

The author then remarks on methods of picking and preparing the tea leaves ; Java tea never undergoes any process or mixing which affects its purity, and it is not scented artificially (1).

It would be impossible to establish, even roughly, any rule for the outlay necessary to establish a tea plantation in the Dutch Indies, and consequently it is very difficult to say how much capital is required to work 700-800 hectares, for example. Everything depends on local conditions, the lie of the land, the nature of the soil the vegetation covering it before clearing, facilities for communications, setting up the factory and, above all, the supply of labour. A well-situated plantation can be worked with a capital of 200 000 to 300 000 *florins* (about 46 000 to 625 000 francs *at par*), while another of the same area will hardly have enough with 600 000 *florins* (about 1 2050 520 francs *at par*).

The experiment station attached to the Department of Agriculture at Buitenzorg is studying many of the questions that arise in connection with the growing and treatment of tea. The result of these investigations is published in a series of pamphlets, *Mededeelingen van het Proefstation voor Thee* (Communications of the tea experiment station). There exists also a tea-examination bureau which examines tea samples from the commercial point of view and gives advice as to modifications which should be introduced into the treatment.

210 – **Brazilian Cocoa**, in *Bulletin commercial de la Section des Affaires économiques et commerciales du Ministère des Relations extérieures*, No. 8, p. 17. Rio de Janeiro, Feb. 1919. (Communicated by Prof. Deoclecio de Campos, Delegate for Brazil to the International Institute of Agriculture).

All species of the genus *Theobroma* are of American origin and were grown by the aborigines before the European conquest.

Chocolate is largely consumed all over the world, and chiefly in the United States. United States soldiers all carry a chocolate ration in their haversacks, and the War Trade Board recognises the importance of chocolate for the use of the army and navy.

(1) Regarding the preparation of Java tea, the observations and experiments made on this subject are described in *R.*, Oct., 1917, No. 955. (*Ed.*)

Before the war, the countries which consumed chocolate on a large scale were the United States, Germany, France, Netherlands, Switzerland and Spain. Since the beginning of the war, Germany found it impossible to import cocoa, and the other countries had to restrict their purchases on account of freightage difficulties. A reduction in consumption therefore took place, and production, which had been continually increasing so as to meet the rising demand, always constant before the war, did not go down, which naturally led to difficulties for the producers. The war being finished, the demand for chocolate should become still greater.

The production of Brazil, which is centred mostly in the States of Bahia and Para, is becoming more and more abundant and by all appearances it will be the foremost in the world in a short time.

The cocoa production for 1918 has been estimated as follows : —

Gold Coast	76 000	metric	tons
Brazil	60 000	»	»
Ecuador	32 000	»	»
St. Thomas	30 000	»	»
San Domingo	23 000	»	»
Trinidad	21 000	»	»
Venezuela	12 000	»	»
Grenada	7 000	»	»
Jamaica	3 000	»	»
Haïti	2 000	»	»
Other countries	28 000	»	»

The total production is over 300 000 metric tons.

The consumption of cocoa has not gone down in any way ; on the contrary it has been always increasing The only effect of the war has been to retard a little its upward curve.

During the years 1914 and 1915 the consumption of the principal importing countries was estimated as follows :—

Countries	1914	1915
	metric tons	metric tons
United States	74 379	84 181
Great Britain	29 038	47 267
Germany	49 707	43 600
Netherlands	32 095	40 955
France	28 140	31 000
Switzerland	10 078	11 311
Spain	6 912	6 512
Austria-Hungary	7 647	5 650
Italy	2 275	4 093
Belgium	6 164	3 800
Other countries	16 463	15 931
Totals	**262 900**	**294 300**

Method of Exporting. — The cacao is exported in bags, the weight of which varies according to the producing country. In Ecuador the bags are of 80 kg.; in Trinidad and Grenada they vary from 80 to 100 kg. and in Venezuela from 50 to 60 kg. Brazil employs a uniform weight of 60 kg., and also the Gold Coast and St. Thomas.

Export from Brasil. — Brazil exported only 20 000 tons of cacao in 1902 but in 1917 the quantity exported came to 55 622 tons, having a value of 48 084 000 *paper milreis* (1) or £2 536 000. The exports of cacao in 1917, by ports of origin, were as follows:

Ports of origin	Kg.	Value in *paper milreis*
Manáos	242 739	181 126
Itacoatiara	221 862	182 435
Belém do Pará	4 255 667	3 811 681
Maranhão	5 210	4 343
Fortaleza	1 771	2 150
Pernambuco	2 288	1 657
Bahia	44 527 063	37 495 015
Victoria	6 600	6 760
Rio de Janeiro	6 202 918	6 253 207
Santos	146 320	146 000

According to counries of destination, the same exports are distributed thus:

Countries of destination	Kg.	Value in *paper milreis*
Argentina	1 110 110	935 609
China	148	144
Denmark	468 000	450 420
United States	37 930 299	32 652 278
France	11 856 822	10 310 228
Great-Britain	274 172	249 125
Netherlands	1 219 000	1 004 129
Spain	274 172	249 125
Italy	265 200	243 030
Japan	1 800	1 746
Norway	482·250	420 091
Portugal	52 371	49 091
Sweden	344 000	293 820
Uruguay	216 000	185 286

211 – **Cultivation of Medicinal and Aromatic Plants in the Royal Botanic Gardens, Naples, Italy.** — *Bollettino dell'Associazione italiana pro piante medicinali, aromatiche ed altre utili*, Year II, No. 11, pp. 164-170. Milan, Nov., 1919.

During the war, the Royal Botanic Gardens at Naples grew many medicinal and aromatic plants, which were studied from the chemical point of view at the Institute of Pharmaceutical Chemistry at the University, and from the physiological standpoint at the Medical and Pharmaceutical Experimental Institute.

The plants experimented with were : castor oil ; digitalis ; belladonna henbane ; stramonium ; mallow : pyrethrum ; balm angelica ; fennel ; *Iris pallida* ; wormwood ; caraway ; patience ; thyme ; camphor tree ; golden seal ; *Rhamnus Purshiana* (cascara sagrada) ; *Convolvolus* sp. ; etc.

A larger area was devoted to castor plants in order to study what would be the best varieties most resistant to drought. By selection fifty varieties were obtained, with a good yield and oil content (from 47 to 58 % in 40 varieties), among which the best are : — *Ricinus sanguineus* in selected forms ; Scafati castor ; some varieties of *R. zanzibariensis* and of *R. Gibsoni* The varieties of the country, namely those cultivated for long in the districts of Verona and Nocera, give an oil yield much higher than that of the Hindoo varieties which before the war provided the greater part of the seed crushed in Italy.

It was found that farmyard manure is a very effective manure to use. Phosphatic fertilisers alone, or better still, along with nitrogenous manures, are good for seed production. Excellent results were got by using silk-worm refuse, alone or mixed with sulphate of ammonia or nitrate of soda. Good results were obtained also with cyanamide.

The light soils of Campania can carry 8 000 castor plants, and give a yield of 16 to 22 quintals of seed, per hectare.

Experimental crops of *Digitalis purpurea* were made on a large scale. Biological estimation of the active principles extracted from the leaves dried in the shade, according to the Focke method (sub-cutaneous injection of a titrated infusion of the leaves in a frog, and observation of the rhythm of the exposed heart) led to the conclusion that nitrogenous manures, as was to be expected, favoured the elaboration of glucosides in digitalis, and that the *fastuosa* and *pelorica* varieties, selected for their stronger growth of leaves, are the most active.

Belladonna (*Atropa Belladonna*) gave two crops of leaves per year, in June and in September. The possibility of using the bracts for pharmaceutical purposes is being studied.

Of henbane (*Hyoxyamus niger*) the type or variety *pallidus* was grown. It requires a fresh, well manured and irrigated soil.

The mallow (*Althaea officinalis*) did well in a rainy year. The roots can be used after 2 years' growth.

Pyrethrum showed itself resistant to drought. It comes up regularly on light volcanic soils.

The officinal balm, wormwood, aniseed, fennel, caraway, patience, valerian, thyme and stavesacre grew regularly and produced large quantities of seed.

The *Iris pallida*, the rhizomes of which were got from Tuscany, grew quite well. Two-year old plants even flowered but this plant is exacting as regards water.

Some specimens of *Rhamnus Purshiana* did well, a fact which indicates the advisability of growing the plant more widely.

On the other hand, the few rare rhizomes of golden seal which the Botanic Gardens were able to procure did not succeed.

The perfume roses (*Rosa damascena*, " Hay's hybrid " and *Rosa centifolia* did very well.

FRUIT GROWING

212 – **A Possible Method for Retarding the Flowering of Fruit Trees.** — DIÉNERT, F., in *Revue de Viticulture*, Year XXVI, Vol. I,I, No. 1328, pp. 379-380. Paris, Dec. 11, 1919.

For a long time fruit growers have tried to get fruit at a time of the year different from the normal crop season. Fruit grown under glass in mid-winter fetches a very high price. By forcing crops in order to obtain these late fruits, however, a rest must be given to replace artificially the natural winter rest ; this is done by menas of anaesthetics or cold.

For certain fruits, it would be of advantage to obtain late crops ; thus, for example, cherries sell much dearer in August than in June. If these could be got in September or at the beginning of October, their sale would be still more profitable (in any case, cherry trees need only a temperature of 8°C. for flowering).

In April, 1919, the author chanced on an experiment that showed how to obtain cherries late in the year. Following on the use of chlorine, the growth of a cherry tree in the open was affected by the vapour and stopped. In September one part of the tree flowered and in October another part. The September flowers yielded fruit about the end of October.

This chance experiment shows that by the proper use of an asphyxiating gas the growth of a tree placed in the open can be arrested and fruit can be had later than the normal season. In this direction there is a field for further investigation.

213 – **Methods for Heightening the Colouring of Fruit.** — TRUELLE, A., in *La vie agricole et rurale*, Year IX, No. 35, pp. 123-125. Paris, Aug. 16, 1919.

Colour counts for a great deal in the market value of fruit, which has to satisfy the consumer not only in taste but also in appearance.

It is admitted that the red colour develops by preference in sunlight and when there are frequent alternations of warmth in the daytime and cooling off at night, as is generally the case in autumn. Morning dew also, according to BECHTLE, has a favourable effect in this respect.

On the basis of these observations, the author advises two operations : — removal of leaves and watering.

Leaves should not be removed all at once or too quickly. They must be taken off one by one and on several different occasions, not by tearing

them off, but by cutting through the middle of the stalk, so as to spare the eyes at the base. They must be removed only in the evening or in dull weather, when transpiration is greatly reduced.

With the peach, which has a very sensitive epidermis, the process must be very gradual, e. g., uncovering the fruit in three operations.

With the finest apple, in particular those of the " Api ,, variety, gardeners grow them in individual bags which they gradually tear off at ripening time. They even turn the apple on its stalk so as to expose several sides to the sun.

Leaf removal is practised also with " chasselas ,, grapes in order to get the golden colour.

Watering consists in spraying with a syringe in the September evenings, when the day has been warm, and aiming preferably at the side exposed to the sun, so as to bring about enlargement and colouring. M. Opoix, chief Gardener at the Luxembourg Gardens in Paris, advises the use of water containing a handful of salt to every 10 litres of water.

214 – **The Forests of Greece.** — Massias, J., in *Revue des Eaux et Forêts*, Vol. LVII, No. 11, pp. 237-247. Paris, 1919. FORESTRY

Extent and Distribution. — In old Greece, as it was before 1913, if all the areas legally considered as forests and superintended by the Forest Service are included, the wooded area would amount to 17-18 % of the territory, a proportion of afforestation similar to that in France. If, however, only the real forest blocks are considered as forests, it may be said there are about 800 000 hectares of forests, or a proportion of about 12 %.

As regards the new provinces, Macedonia, Epirus, Crete and islands of the Aegean Sea, it is estimated that the wooded areas represent about 14 % of the territory. Generally speaking, the forests of Macedonia and Epirus are much richer than those of old Greece. In Crete and in the Aegean Sea islands forests are not very numerous except in a few cases, as for example in the island of Thassos.

It results from the foregoing figures that for the whole of present-day Greece, including the new provinces, the wooded area amounts to about 13 % of the country. From the point of view of ownership, about 50 % of the forests belong to the State, 20 % to convents or to communes, and 30 % to private individuals.

Composition.— For the provinces of old Greece, the only parts for which at present fairly precise data are available, the proportions of the various species is something like the following : — Aleppo pine 30 % ; spruce 25 % ; oak 20 % ; larch 5 % ; beech 5 ; various : — chestnut, *Pinus pinea*, hornbeam, elm, maple, ash, lime fruit trees, etc., 10 %.

Oaks are represented by numerous species, the proportion of which is much as follows : — *Quercus conferta* 35 % ; *Q. pubescens* 35 % ; *Q. Aegilops* 10 % ; *Q. Ilex* 8 % ; *Q. sessiliflora, Q. pedunculata* and *Q. Cerris* 12 %.

Production. — The total annual production of the Greek forests

and the corresponding value may be estimated as follows for the period 1905-1911 : —

60 000 cub. metres of timber, worth	3 000 000	fr.
15 million *zygies* (1) of firewood, worth	15 000 000	»
16 million *okes* of charcoal, worth	2 400 000	»
10 million *okes* of resin, worth	3 000 000	»
8 500 000 *okes* of vallonia, worth	1 300 000	»
Various products (tanning and colouring matter)	300 000	»
Total	25 000 000	fr.

In addition, about 370 000 quintals of lime, valued roughly at 1 million francs are produced in the forests, and grazing for sheep and goats constitutes an indirect product which may be valued at about 7 million francs.

Hence the total yield from the forests of old Greece would represent about 33 million francs, but this is quite a theoretical estimate intended merely to show the part played by the forests in the total national wealth, since a large proportion of these products is not transformed into money.

The foregoing figures show how great a value, in the total production, the by-products have, compared with the main product, namely timber. Thus, in some privately-owned forests, the revenue brought in by the letting for grazing and the sale of resin is much higher than that from the sale of charcoal and wood. This disparity is naturally all the greater, the worse the estates are managed as regards forests. On the other hand, it may be observed how low the proportion of commercial timber is compared with firewood. This is due to various causes : primarily the composition of the woods and the low fertility of the soil, the poor management of the forests, the large number of illegal actions, and in particular the customary rights of the peasants to firewood, with the resulting abuses.

This deficient production of timber necessitates the annual importation into Greece of over 100 000 cubic metres of timber, a quantity much greater than the home production.

Regulations and Administration. — In Greece, all forests, whatever their ownership, come under the forest regulations. There is no forest code, but the laws are the result of a large number of texts, some of which are already very old. During the last few years, however, the insufficiency of these laws has been remarked and attempts have been begun to complete them. Two recent laws in particular deserve mention : one dealing with fires, the other with reforestation.

Greek forests, especially in the low-lying districts where Aleppo pine predominates, are much exposed to ravages by fires, which are sometimes intentionally lighted by shepherds. A law passed in 1914 prescribed excellent measures both for lessening the number of fires and for minimising the resulting damage. These provisions consist mainly in pro-

(1) 1 *Zygie* = 1 000 *okes* ; 1 *oke* = 2.75 lb. (*Ed.*)

hibiting the lighting of fires in any forest during summer,in creating safety fire-belts and in protecting burnt areas for 10 years.

Much will have to be done in Greece as regards the restoration and re-wooding of the mountains. On the slopes of many mountain chains there are huge stretches of formerly wooded ground which have been reduced to the condition of waste land or entirely denuded through abuses in exploitation or in grazing and through fires. The question of re-planting was the object of a special law, passed on May 3, 1918, which provides for the setting up in each commune of a Reforestation Commission including the head of the commune and 4 members: officers or private owners. These Commissions will be nominated to specify the areas where re-planting or protection is necessary. The protection of the ground may consist mostly in forbidding or regulating grazing and exploitation. The work of re-planting will be carried out either by the proprietors or by the State, after the purchase of the ground by agreement or by expropriation.

Two new laws passed by the Parliament December 26, 1918, will allow of several important improvements being realised soon.

The first of these laws regulates the method of management, as regards exploitation, of forests belonging to estates, communes, public and private establishments, as well as of those under litigation and unallotted, it revises and codifies the existing customs with regard to rights of usage; especially the gathering of firewood by the peasants, giving the local authorities the right of determining the enforcement of the provisions; and in connection with taxes, it slightly modifies some of the tariffs at present in force.

The second law establishes the basis of a new organisation of the Forest Service. In future the staff will include 20 inspectors, 120 district chiefs, 50 head foremen, 150 foremen and 850 guards. The recruiting of the lower grades of staff will continue to be done from the two guards' schools, but in order to be able to fill quickly the extremely numerous vacancies that exist at present, the law provides, as a temporary measure, for the admission to the forest service of ex-soldiers, preferably non-commissioned officers, who will be nominated under-guards and will be promoted only after being passed by one of the schools for guards. As regards agents, a measure of this nature is not practicable, and it is only in a few years that the working of the Higher Forestry School at Athens, established in 1917, will enable the present shortage of staff to be made up. Only then will the new organisation be able to be put fully to work and many of the reforms involved be able to be realised.

215 – **The Forests of Madagascar** (1). — GRANDIDIER, G. (General Secretary of the Geographical Society), in *Revue générale des Sciences*, Year XXX, No. 21, pp. 624-629. Paris, Nov. 15, 1919.

Madagascar is not much wooded : the central heights are practically devoid of trees and the southernmost part, where the climate is very dry,

(1) See *R.*, March, 1919, No. 274, p. 275, and *R.*, June, 1919, No. 742, Part XII, p. 758. (*Ed.*)

shows only a scrub with occasional trees and plants adapted to dry conditions. The only really wooded parts are: —

1) First, and mainly the eastern side, along the whole of which extends without a break, from Fort Dauphin to near Vohémar, to a width of 50-70 kilometres, the great eastern forest, composed almost entirely of evergreen trees and cut into by numerous and vast "sahavoka", bare or unwooded, immense glades covered with large herbaceous plants, bamboo, "ravinala" or travellers' trees, and small thickets.

2) Secondly, the western region, where the trees, whose leaves fall during the dry season, form more or less extensive forests, distributed here and there over the whole of this zone, and stretching parallel to the coast from Cap d'Ambre to Onilahy in wide belts which are not continuous and do not present unbroken forest as in the eastern region, but form large blocks intersected by bare spaces or, more often, by plains dotted with isolated trees or thickets.

The author describes these forests of Madagascar and enumerates the chief species composing them (according to the Rev. R. BARON, in the west there is scarcely 4 % of the plants to be found in the east). He then studies, with a historical review of the subject, the lumber trade of Madagascar, the timber itself and its uses, with its commercial value. Lastly he treats of the rubber and copal provided by the plants of Madagascar, and ends up with some considerations of a general kind on the increase and improvement of the forest production of the colony.

216 – **A Study on *Hibiscus tiliaceus*.** — HENRY (Technical Director of the "Société Française des Îles Marquises", at Jaiohae), in *Bulletin de la Société Nationale d'Acclimatation*, Year LXIIV, No. 11, pp. 343-345. Paris, Nov., 1919.

Hibiscus tiliaceus L. (= *Paritium tiliaceum* A. St. Hil. = the Burao of the Tahitians = the Hau of the Marquesans) is the, forest species in the islands of French Polynesia. It is to be found everywhere, in the valleys, on the highest summits, in damp places, in the driest parts, but it always indicates a fair degree of moisture in the subsoil when it is growing in places that appear on the surface to be arid.

Although the forms of this plant are comparatively varied, they appear to belong to a single species (even the *tricuspis* variety, which is doubtless only a dimorphic form, and another variety which is characterised by its wide polymorphy).

The uses of the wood of *Hibiscus tiliaceus* are comparable to those of walnut. It provides knee pieces of value in shipbuilding, and when seasoned it takes on a dark tint and provides a fine wood for cabinet making, especially the small-leaf varieties which have a finer grain and closer fibres. The young stems when ripened in the sun yield strong fibre suitable for making cheap cordage for home use. The wood varies in quality according to the shape of the leaf; the best and hardest is that from small-leaved trees whether they grow alone or along with other varieties.

These characteristics are constant, and generally the different varieties are found growing together in groups.

The *tricuspis* variety appears to be confined to Tahiti and to the Leeward Islands.

LIVE STOK AND BREEDING.

HYGIENE

217 – **The Toxicity of Cacao Husks for Livestock.** — MARCHADIER and GOUJON (Director and Chemist in the Laboratoire Municipal agréé du Mans), in *Annales des Falsifications et des Fraudes*, Year XII, No. 131-132, pp. 283-297. Paris, Sept.-Oct., 1919.

It is well known that the cacao fruit is a fleshy one, in whose pulp the seeds are set, the kernels of which are used in the manufacture of cocoa. The husk or shell of cacao is the perisperm of the seed. It is a membrane of no great thickness which completely surrounds the kernel and is very friable, especially when roasted, as is generally done in the case of husks used for stock feeding. Cacao husks are used on a large scale at the present day in the preparation of theobromine, an alkaloid much used since 1890 in the treatment of heart troubles. Besides this the husks also provide, on extraction with steam, cocoa extracts which are in great demand for confectionery aud which, on account of their high content of caffein, are used also in the manufacture of certain coffee substitutes, such as malt coffee. It is possible also to extract from them a brown colouring material soluble in alkalis and of a fast colour. Finally, as they have a high content of assimilable iron, the husks serve as a basis for certain medicinal preparations used for anaemia.

As regards the use of cacao husks for stock feeding, the authors declare that : —

1) The raw husks are dangerous, at least for horses, and the sale of them should be controlled.

2) The husks, when their extracts have been removed, are of no food value, and the sale of them for stock feeding should be forbidden.

218 – **Haemorrhagic Septicaemia.** — WASHBURN, H. J., in *U. S. Department of Agriculture, Bulletin* No. 674, pp. 9. Washington, May 15, 1918.

Bulletin dealing with the following points: — Characteristics of this disease ; History ; Causes ; Symptoms ; Anatomical changes which it causes ; Diagnosis ; Prevention ; Treatment ; Disinfection of premises.

Haemorrhagic septicaemia is an infectious disease which attacks various species of animals, especially cattle, sheep and pigs Young animals are more susceptible to it than older ones; those which are thin and poorly nourished are most liable to infection. The disease is a poisoning of the blood which often rapidly proves fatal In suddenness of attack and high mortality at the beginning of an outbreak this disease much resembles anthrax.

In pigs the disease is called " swine plague " or contagious pleuropneumonia The acute form is usually fatal within a few hours from the appearance of the first symptoms. The acute form causes gradual weakening and emaciation and may last several weeks.

Fowl cholera is the form of haemorrhagic septicaemia affecting poultry ; it causes sometimes heavy losses among fowls, pigeons and geese. The outbreaks are generally so rapid in their effect that no treatment is possi-

sible. As soon as the disease appears the apparently healthy animals should immediately be separated, placed in clean quarters and given good food and water. In many cases inoculating the healthy animals with Bacterins has proved effective in checking the spread of an epidemic.

In the United States haemorrhagic septicaemia occurred for the first time many years ago in the form of " swine plague ". In 1885, the Bureau of Animal Industry identified the *Bacillus bipolaris suisepticus* as the cause of the disease, identical with the " Schweineseuche " of German writers.

Curative treatment is useless. Preventive treatment by means of bacterins obtained from the same species as the animal to be treated (*B. bovisepticus* for cattle, *B. suisepticus* for pigs, etc), or else by means of an attenuated culture of the living organism, has often given satisfactory results. Isolation of the uninfected animals and disinfection of their quarters are most important measures.

219 – **Typhoid Fever and Infectious Anaemia of the Horse.** — Basset, J., in *Comptes rendus de la Société de Biologie*, Vol. LXXXII, No. 31, pp. 1262-1263. Paris, Dec. 6, 1919.

In previous papers (1) the author has shown : — 1) that typhoid fever in the horse is inoculable, being caused by a filtrable virus ; 2) that the virus is present in the blood, where it remains *in vitro* for over 15 weeks, and *in vivo* for about 5 months ; 3) that a first attack of the disease confers complete and immediate resistance *experimentally* for at least 4 months, and *clinically* for 18 months ; 4) that at the beginning the fever is present alone for 2 or 3 days, and that, consequently, in times of epidemic the thermometer serves to diagnose the start of the disease and ensures forthe patients the best chances of recovery.

As doctors and experimenters have been struck by the close similarity in the symptoms shown by horses affected with typhoid fever and those suffering from the acute form of anaemia, the author tried to find out if it were a case of distinct morbid entities and to compare them. Experiments on the subject show that : —

1) The two diseases are absolutely distinct ; 2) they are very different, because, contrary to typhoid fever, infectious anaemia is essentially chronic ; in the case of anaemia, as in the chronic forms of many diseases due to microbes (tuberculosis, farcy, malaria, etc.) the equilibrium of the organism is at the mercy of a more or less mild, common, or specific cause.

The author proposes to base on these experimental results a method for diagnosing anaemia. Dieases due to parasites visible in the blood having been eliminated, the diagnosis will be based on the remittence or intermittence of the fever. In the absence of spontaneous feverish attacks, these will be brought on by injection, into the blood, of serum from any horse (2).

(1) *Comptes rendus de l'Académie des Sciences*, August 21, 1911 ; *Recueil de med. vétér.*, Sept. 15, 1911, Feb. 15, 1912 ; *Bul. Soc. cent. med. vétér.* March 12, 1912. (*Authors' note*).

(2) And perhaps more simply by the injection of salt water in sufficient quantity (the author has at present no subjects on which he can verify this hypothesis). (*Authors' note*).

It is not at all necessary to bring about several attacks of fever; a single one *brought on*, appearing about 24 hours after the disturbing infection, will assure the diagnosis.

220 – **A Contribution to the Study of Anaplasmosis in Cattle: Sheep and Goats are Susceptible.** — LIGNIÈRE, J., in *Bulletin de la Société de Pathologie exotique*, Year XII, No. 9, pp. 641-651. Paris, Nov. 12, 1919.

Inoculation experiments with *Anaplasma argentinum* on several species of animals showed that :—

1) The guinea pig, rabbit, pig and horse do not seem to be affected by *A. argentinum*.

2) Sheep and goats, on the contrary, are receptive to the parasite, which remains alive in the blood for years.

3) The passage from sheep to sheep or from one goat to another is possible indefinitely.

4) The inoculation with *A. argentinum* of sheep or goats never gives rise to symptoms or lesions of anaplasma, or to typical parasites visible in the red blood corpuscles ; the temperature is not altered, except sometimes about the 30th day, when a rise to 40-41° C. may be found for 1 or 2 days only ; even during this passing fever, when it exists, nothing abnormal is observed about the animal, and the blood colourations do not reveal *Anaplasma* as such ; the parasite, however, exists in the red corpuscules, as proved by inoculation, but the author thinks it is to be found there in so small a form that it is difficult to recognise.

5) The blood of sheep and goats previously inoculated with *A. argentinum* is active when injected into cattle which take anaplasma infection ; there is a posibility of attenuating the *A. argentinum* in the sheep and of using their blood as a vaccine against bovine anaplasmosis.

221 – **Curative Treatment of "Bush Sickness" by Iron Salts in New Zealand.** — REAKES, C. J. and ASTON, B. C., in *The New Zealand Journal of Agriculture*, Vol. XVIII, No. 4, pp. 193-197, 2 fig. Wellington, April 21, 1919.

The authors have made, at Mamaku Farm, a series of experiments consisting in giving medicinal compounds (either in the form of brick-licks or as drenches given by hand or in the drinking water) which contained elements known or suspected to be deficient in the local soil in the lands which caused " bush sickness " (1).

Summarizing the results obtained up to date it appears that, of the mineral preparations tested, the administration of phosphates, or iron salts to cattle grazed on pasture dressed with phosphates, keeps them in good health for a much longer period than would be the case without that treatment and dressing. But, on the other hand, it appears that it is only by drenching (by hand or in drinking water) with a syrup of phosphate of iron that the animals can be kept indefinitely in good health or cured of " bush sickness ". Of organic compounds the double citrate of

(1) See *R.*, March, 1916, No. 316. (*Ed.*)

iron and ammonium cures " bush sickness " more quickly than syrup of phosphate of iron. It is probable that other organic salts of iron would be equally effective.

222 – **Observations on Avian Malaria.** — SERGENT, ÉTIENNE (Pasteur Institute of Algeria), in: I. *Bulletin de la Société de Pathologie exotique*, Year XII, No. 9, pp. 601-603. Paris, Nov. 12, 1919. — II *Do.* pp. 603-605. 1 diagr.

I. — It has always been agreed, with RUGE, that *Plasmodium* is pathogenic for the carrying insect to such an extent that, when experiments are to be made by infecting mosquitos with parasitised blood, care should be taken not to use birds very badly infected.

It appears, in fact, that when the insect shows on its stomach wall a certain number of cystic tumours as large as 60 μ (the stomach being on the average 1 500 μ long and 800 μ wide) these foreign bodies must cause some trouble in the functioning of its organism.

On the other hand, on the basis of the statement that insects fed on blood very rich in parasites are decimated by this excess of virus, it would be logical to believe that, following on a severe epidemic (e. g., with superabundance of blood-infecting *Plasmodium* of human malaria), there would be a diminution in the numbers of infected transmitting mosquitos, a thing which has never been clearly proved.

The author has found in the laboratory that *Plasmodium* is not very pathogenic for the insect carrying the virus. He observed several hundred cases of mass infection by *Plasmodium relictum*, an agent causing malaria in birds, in *Culex* of which each individual carried at least 100 zygotes at their maximum development ; he never observed a greater death rate among them than among the control *Culex* (i. e. those with only a few zygotes in their bodies) or among fresh *Culex* which had not been fed on *Plasmodium* infected blood. Hence the full development of *P. relictum* in *Culex* does not appear to involve disturbances fatal to the insect.

II. — In malaria of birds, after an incubation period of 3 to 10 days, there occurs an acute infection of the blood, during which *Plasmodium* is very prevalent for about a week. Then if the bird survives, the parasites quickly (in 3 or 6 days) become very rare. Some irregular attacks occur for a few weeks and precede final recovery or the state of latent infection which confers comparative immunity, without the parasites being visible in the peripheral blood.

After investigation, the author has found that in avian malaria the blood of the vertebrate is very infectious to the insect for the fortnight following the acute stage, in spite of the low number of parasites in the bird's blood during this period.

FEEDS AND FEEDING

223 – **Concentrated Cattle Foods used during the War.** — GUILLIN, R. (Report on work done in the Laboratory of the French Farmers' Society in 1917 and 1918), in *Bulletin de la Société des Agriculteurs de France*, pp. 173-174. Paris, June, 1919.

The subjoined table gives some interesting analyses of concentrated foods used during the war. A few unusual products will be noticed, which were resorted to on account of the shortage of foods.

Seaweed, washed and dried, has been used as fodder ; chestnuts have served as starchy food ; also bran from various grains has been utilised, some kinds of remarkable composition, others of little value.

Percentage composition of various cattle foods.

	Protein	Fats	Carbo-hydrates	Cellulose	Mineral matter	Water

Buckwheat bran.	7.15	1.16	44.19	30.60	2.60	14.80

(1) Sodium chloride 0.24 % ; phosphoric acid 15.74 % ; lime 20.20 %.
(2) Phosphoric acid 5.76 % ; lime 7.70 %.

The table also shows the composition of dried coffee chicory husks. Coffee chicory is subject to fairly considerable variations in price ; some years, in consequence of super-abundance, there is a fall such that selling does not pay and even is very difficult. In that case, husks of coffee chicory can be used as cattle food ; they constitute a good carbohydrate food, of similar feeding value to sugar beet, although in the chicory root synanthrose predominates instead of saccharose, as in the artichoke.

BREEDING

224 – **Results of Crossing the Zebu with European and Australian Cattle, in British and Dutch India.** — T'Hoen, in *Cultura, Officiel Orgaan van het Nederlandsch Genootschap voor Landbouwwetenshap*, Year XXXI, No. 374, pp. 369-374 + 5 figs. Wageningen, Nov. 1919.

In tropical colonies, repeated of attempts have already been made to cross *Bos taurus* with the zebu, so as to combine the beefproducing capacity and productivity of the former with the adaptability of the latter to the local conditions and its special resistance to disease.

The author describes the results of a series of crosses between the Neellore breed of zebu on the one hand and the Java ox and some European and Australian cattle on the other hand.

The zebu of Neelolre (Madras, British India) is an excellent working animal ; it measures 1.40 to 1.50 metres at the withers ; the female gives a high yield of milk, 8-10 litres per day with a fat content of 4.5 to 5 per cent. From the cross zebu × Java cattle, draught types were obtained but they were poor milkers. By crossing Neellore zebus with Australian or Dutch cattle, animals were obtained which gave a good production of beef and a milk yield which, although less than that of their European dams, was nevertheless above that of the zebus, and such as to make these hybrids of great value in the warm damp coast regions of the Dutch East Indies. The fat content of their milk is 4 % and even over. The castrated males make splendid draught animals ; the author mentions a pair (sold on the Malang market) which measured each 1.50 metres in height and 2.20 metres round the chest.

By using as sires, in these crosses, males of European breed, the zebu characteristics quickly disappear, and in the 3rd generation the progeny cannot be distinguished from pure-bred European cattle.

The importation of bulls and dairy cows from India, Europe and Australia is regulated by the State. The European and Australian types concentrated in the central mountainous territory, where the altitude moderates the temperature and keeps it between 15° and 30° C., can become acclimatised and breed regularly.

The results already given by scattered and un-coordinated attempts promise the best of prospects for the future, especially when the work is carried on according to a uniform method and with a well-planned programme of work.

The example of British India, gives an idea of the results that can really be obtained by the crosses in question. The Montgomery (Zebu) cow has been mated with the Ayrshire bull, with a view to raising the milk yield of the zebu type. While the Montgomery cow yields on an average 8-10 litres of milk per day, at the second generation of the cross a daily yield of 15 litres has been attained.

STOCK RAISING AND ENCOURAGEMENTS

225 – **Domestic Animals in Syria.** — Dechambre, Ed., in *Comptes rendus des séances de l'Académie d'Agriculture de France*, Vol. V, No. 29, pp. 975-976 and 995-1002. Paris, Dec. 17, 1919.

The author (Veterinary Adjutant-Major with the French troops in the Levant) has studied the different aspects of animal production in Syria.

The contour of Syria is very varied ; it includes high mountains like Lebanon and Anti-Lebanon, and vast plains like the Beka, which stretches between the above two ranges.

Except for some parts of the Beka plain, the neighbourhood of the towns and a part of Lebanon, the country is badly cultivated. The soil is fertile in many parts, but suffers from lack of water. In fact, during the whole summer, from April to November, there is no rainfall and the drought is extreme ; growth is practically at a standstill and the ground is covered only with hard dried grasses, mostly spiny. Only in spring is vegetation luxuriant, and many herds are fed on it.

Livestock is one of the main sources of this country's wealth, but on account of the difficult conditions under which it subsists, improved breeds cannot be found there.

Exact figures as to the numbers of animals are not available, the only statistics on the subject dating from 1895.

Cattle. — The type is uniform, constituting a true breed, and has great similarity to that of Lower Egypt, but is rather more developed. The height is small (1.15 to 1.30 metres on the average) ; head rectilinear, nape somewhat prominent ; horns always very short, growing sideways and upwards, turned down only in some cases ; neck short, dewlap much developed ; back straight, rump short, thigh rectilinear, udder very small, sometimes scarcely visible between the hind legs ; colour dark fawn with some white spots ; bulls almost black with shades of fawn on forehead, nape and back ; hair rough, skin thick ; they hardly ever handle well, as there is no covering fat, even on animals in condition ; internal fat scarce, located about the loins. The cows give little more than 80 kg. of meat net, and hardly ever as much as 100 kg.

In the Damascus region much more developed, specimens are to be seen but their race characteristics are similar.

There are also somewhat larger cattle light grey, ash-coloured, and with fairly long turned-up horns. These are likely cattle from the north ; they are similar to the animals seen at Smryna and Constantinople.

Sheep. — These form one of the sources of the wealth of Syria. Unlike cattle, they grow very well on the immense plains that are covered with numerous flocks.

In general the size is fairly large ; the tail is very big, loaded with fat, and quite unlike that of the Barbary sheep (large mass as wide as the back, often reaching to below the hocks, then turning sharply back and upwards, narrowing a little, and ending in a loose part, 20 to 25 cm. long, like the tail of a European sheep) ; generally no horns ; when they are present they are short and turned backwards ; some specimens have very long spiral horns (40-45 cm.) at both sides of the head ; colour white with some brown or black spots, but the colouring may extend over all the head and even a large part of the body. The wool does not cover the face and does not come past the knees or hocks ; it is not too coarse, 7-8 cm. long, wavy and somewhat curly ; the fleece is not thick.

In the south of Palestine, very large sheep are found, without horns,

with long black fleece, tail very big but conical and elongated. These supply almost all the local consumption needs. Their flesh is of fine quality but almost always has a strong disagreeable odour.

Goats. — These are extremely numerous all over Syria, and in many parts fom larger flocks than the sheep.

The type is less uniform and less charactersistic than that of sheep and cattle. There are two distinct breeds, but these are frequently cross bred : —

1) A breed of fairly big goats with very long ears, without horns (or with very small ones turned backwards), of black colour more or less marked with white, with hair very long (15-20 cm.), stiff and hardly waved, udder much developed. This breed is excellent for milk. It is the same breed as is found round about Beyrut, which it supplies with the greater part of the milk consumed there.

2) The immense flocks of goats on the plains of the interior are of a quite different type. The size is less developed, ears are small, and erect, and horns long, in elongated spirals at each side of the head. The coat is black with some white spots. The fleece is shorter than that of the other breed.

Horses. — The number of head is much lower than for the preceding classes. Syrian horses enjoy a worldwide reputation, but requisitions by the Turks have spoiled their future.

These horses are of small size, spare, and muscular, the coat is very light grey, often spotted, or chestnut ; the face has a slight dip in the supranasal bones.

At Damascus there are horses which correspond better with the classic type of Arab horse : big, generally bay, rectilinear outline, face flat supranasal bones not dished, nostrils widely opened and squarely cut.

Mules. — These are fairly numerous, of good size, muscular, resistant, used almost entirely for the pack saddle.

Donkeys. — Very numerous ; small, like those of North Africa at Damascus, a large proportion have absolutely white coats.

Camels. — Much used for transport ; of the humped species numbers reduced by requisitions of the Turks.

Poultry. — Very abundant everywhere. Fowls are of small size, as large as good partridges ; the plumage is mottled white, red and maroon. Before the war Syria exported a large quantity of dried eggs.

Like all poor and arid countries, Syria is a country where only sheep and goats can thrive. It is likely that France might be able to utilise these appreciable resources. The native consumption is not sufficient to require the Syrian flocks. If the Arabs continue rearing without good outlets for their products, it is because, for them, flocks constitute a visible sign of wealth. It is not even doubtful that they would agree to dispose of their stocks for gold or silver.

In regard to cattle, it would be best to consider them entirely as draught animals and use them for agricultural work. When methods of cultivation become improved and when crops become more abundant and more re-

gular, then the grading-up of the herds of cattle will be able to be taken in hand. For this purpose, selection of the native breeds or the introduction of French breeds may be resorted to. It will be advisable, however, to be careful in using the latter method. In order to avoid much loss of time and costly failure, it will be wise to take into account the results to be got by this method, under similar conditions, in North Africa, in Tunis and especially in Morocco.

226 – **The Distribution of High-Class Breeding Stock by the Government, in Saskatchewan, Canada, from 1913 to 1918.** — *The Agricultural Gazette of Canada*, Vol. 6, No. 11, p. 978. Ottava, Nov., 1919.

The Live Stock Branch of the Department of Agriculture for Saskatchewan has published returns on the working of the Live Stock Products and Sale Act. The returns show the net results of the efforts of the government to introduce by means of this new law pure bred and high class grade stock into Saskatchewan. The totals under the different classes of stock show a very satisfactory increase from the year when the law came into force (1913) up to 1919.

In all, 17 261 breeding animals have been supplied to 2 067 farmers on favourable conditions. Table I shows the complete record of animals supplied by the Department since the year when the act first came into operation, and Table II shows the number of farmers who have taken advantage of the assistance and facilities offered by the Department in virtue of this act.

TABLE I. — *Numbers of breeding animals distributed by the Government between* 1913 *and* 1918.

Years	Pure-bred bulls	Pure-bred cows	Grade cows and heifers	Pure-bred rams	Grade ewes	Swine	Total animals
1913	19	18	345	—	1000	—	**1382**
1914	41	14	483	13	482	2	**1035**

HORSES AND MULES

227 - **The Service of State Stallions in Italy during 1919.** — Moreschi, B., in *Giornale di Agricoltura della Domenica*, Year XXIX, No. 37, p. 269, Piacenza, Sept. 14, 1919.

At the end of July, 1919, the State stallions had served 62 977 mares, distributed as follows among the districts belonging to the different centres : Crema — 15 857 ; Ferrara 10 850 ; Santa Maria di Capua 9 815 ; Reggio Emilia 7 815 ; Ozieri 8 670 ; Pisa 5460 ; Catania 5384. As the stallions, contrary to regulations, continued to be used after this date in many districts, the above figures will have to be slightly modified. The total number of mares served in 1916 by government sires was 46 033. Hence there is a considerable increase in the last few years ; in Sardinia it amounted to 50 % from 1918 to 1919. Estimating the number of stallions in service during 1919 at 1 110, each of them them served on the average, 57 mares.

228 - **Mules in French West Africa.** — Loyer, M., in *Bulletin de la Société Nationale d'Acclimatation*, Year LXVII, No. 11, pp. 332-233. Paris, Nov., 1919.

The substitution of animal traction for human porterage is of great economic and social importance in French West Africa.

A mule yoked to a light cart is capable of transporting 500 kg., or the loads of 20 men (a man's load is 25 kg. for 25 kilometres per day, on the average). It costs in food only 25 centimes per day and hiring charges come to 1 franc per day at most, with food and attention included. A mule driver in charge of 3 mules and 3 carts will cost 1 franc (men porters cost from 90 centimes to 1 franc per day, including their return journey).

Mules alone can serve for this purpose, as the African horse is no good for draught on account of its breed, and oxen can take only 100 kg. and do not stand up to long journeys.

Under such conditions it is necessary to breed mules fit to fulfill the conditions of transport in West Africa, and the selection of stallions should be specially investigated. The Poitou jack donkey must be discarded, as it gives a mule that is slow, heavy, too big, a bad resister of heat and one troubled with hoof splitting ; the Pyrenees jack must also be discarded, although it would give a mule of the desired size. The most suitable mule is the medium artillery one, sired by the Spanish or Moroccan jack ; it is of small size and is not liable to foot troubles.

In Africa, the mule exists only accidentally (1) as the natives, although they greatly appreciate the animal, refuse to breed it deliberately under the belief that it is the result of a mating contrary to nature.

It is necessary to breed mules on the spot, because those sent to French West Africa are too expensive. There are suitable animals in French W. Africa, especially in the Volta basin, but service is difficult, as the native jack is indifferent. On the other hand, the European jack donkey and the Moroccan which have already served do not give rise to this inconvenience.

(1) The latest census in French W. Africa (1912) gives 116 000 horses, 7 800 000 cattle, 5 500 000 goats, and 4 500 000 sheep, but mules are not mentioned. — See *R.*, Feb., 1919, No. 146. (*Ed.*)

To the advantages to be gained by using mules for transport must be added those that would be provided in ploughing, which neither oxen nor horses can manage in tropical countries.

CATTLE

229 – **The " Maoilin " Breed of Cattle in Ireland.** — MITCHELL, S. L., in *Hoard's Dairyman* Vol. LVII, No. 11, p. 551, Fort Atkinson, April. 4, 1919.

The Irish " Maoilin " breed of cattle, hornless, with dark brown yellow coat, generally whole coloured sometimes spotted white on the head and shoulders, is very ancient and at the present time there are only 8 or 9 herds. Several skulls of animals of this breed have been found in the " crannogues " (1).

According to some writers, the native home of this breed stretches east of the Shannon through Longford, Westmeath, Kings County and Tipperary ; at the present time it is found chiefly in the west part of the island from Donegal to Cork. The distinctness of the breed is shown by the fact that, however much crossed, it is dominant and recognisable even to the 10 th. generation. It is due to this fact that the breed is not to day entirely extinct. A society has been formed for re-establishing this breed.

" Maoilin " cows are excellent milkers ; they give from 8 to 10 gallons a day in summer and 4 or 5 gallons a day in winter of delicious rich milk. They are not liable to any disease. According to the author the hornless character of some of the present Scotch and English breeds may be due to cattle introduced into East Anglia and Scotland by early Irish colonists.

230 – **Inheritance of Quantity and Quality of Milk Production in Dairy Cows.** — CASTLE, W. E., in *Procedings of the National Academy of Sciences of the United States of America*, Vol V, No. 10, pp. 428-434. Washington, October, 1919.

In 1911, Mr. T. J. BOWLKER undertook, at his farm in Framingham (Massachusetts), an experimental study on a large scale of inheritance in dairy cows by the modern method of crossing pure breeds and looking for a combination, in the 2nd crossbred generation, of the characters differentiating the breeds used in crossing. The breeds which he selected for trial were the Holstein-Friesian (which surpasses all others in the quantity of milk produced) and the Guernsey, which is distinguished for the quality of its milk. He started with the idea that, if the quantity and quality of milk production were independently inherited characters, it should be possible to combine them in a single breed by crossbreeding, in accordance with MENDEL's laws. The experiments were continued at Framingham up to 1919, and will be carried on by the University of Illinois.

The Holstein cows were mated with a Guernsey bull and the Guernsey cows with a Holstein bull. Altogether, between 1912 and 1919, 140 F_1 calves were produced ; by mating F_1 heifers with F_1 bulls, 35 living F_2 calves were obtained, all vigorous and well grown. The F_1 cows calved

(1) The Irish name for a kind of blockhouse used in ancient times as fortresses by Irish chiefs and which were generally built on islands. — Cf. *Nouveau Larousse illustré*. Paris, Librairie Larousse. (*Ed.*)

for the first time at a slightly earlier age than the cows of either pure breed, which is evidence of their vigour and early maturity.

The following data have been taken from the tables showing the milk and butter-fat production for the 1st and 2nd lactation periods of the pure bred cows and of those crossbred :—

Milk and butter-fat production of cows of pure Holstein and Guernsey breeds and of cows bred by crossing them.

Breed	Number of Cows	Average age at calving	Average quantity of milk produced	Percentage of butter-fat	Average quantity of butter-fat produced
		1st. lactation period.			
Holstein	25	2.8 years	7 673 lb.	3.4	261 lb.
Guernsey	8	2.7	4 617	5.0	230
F_1 crossbred	31	2.6	6 612	4.08	270
		2nd. lactation period.			
Holstein	20	4 years	9 475 lb.	—	322 lb.
Guernsey	8	3.8	5 593	—	280
F_1 crossbred	13	3.9	8 663	—	363

In the 1st lactation period, and still more in the 2nd, the F_1 crossbred cows gave results superior to the mean between the results given by the pure breeds producing them both as regards the quantity of milk and fat. But the record of variations relatively to the mean in the case of F_2 crossbred cows must be awaited, unless the quality and the quantity of milk production are transmitted by independent factors ; in that case it should be possible to combine them and to obtain inheritance transmission.

The two reciprocal crosses differed very slightly, and inversely in the two lactation periods ; it seems, therefore, unlikely that any sex-linked factors are concerned.

231 – **Cattle Feeding Investigations in Kansas, U. S. A.** — *Kansas Agricultural Experiment Station, Report for the year* 1917, pp. 28, 29, 39, 40. Manhattan, 1918 ; *Report for the Year* 1918, pp. 40-42. 1919.

Eighty-four grade Hereford calves from the Fort Hays agricultural substation were divided into six lots and full-fed for the production of yearling beef. Four lots were used to compare good sweet-clover hay and green, brown and black alfalfa hay. The concentrates used were shelled maize and oil meal. The black alfalfa had been stacked immediately after cutting without being cured. It was charged at $5 per ton, whereas the price of the other hays was put at $15.

The black-alfalfa lot was given almost twice as much hay as the other lots but ate somewhat less grain. The gain averaged lowest and was the most expensive of any lot with grain. The green-alfalfa hay lot made

slightly better and more economical gains than the brown-alfalfa lot. The lot fed with sweet clover hay made about the same gains as the green-alfalfa hay lot, but these were cheapest.

The two remaining lots were used to compare ground maize, barley, and linseed meal with shelled maize and linseed meal when the roughage consisted of brown alfalfa and silage in both cases. The maize and barley lot made the fastest gains of any of the six lots, but next to the black-alfalfa lot these were the most expensive. The other lot made rather low but cheap gains.

Progress is reported on a project at the Fort Hays sub-station concerning the development of breeding heifers. During the second winter of the experiment the cows which had calved at 3 years made better gains than the group that calved the succeeding spring as two-year olds. In both groups the lots receiving maize and cotton-seed cake in addition to roughage averaged somewhat less than twice the gain of lots fed with only alfalfa hay silage and wheat straw, but at somewhat more than twice the cost In the case of 2-year olds, the grain-fed lot had less trouble in calving.

At the Kansas agricultural station at Manhattan, 5 lots, each consisting of 6 steers and 4 spayed heifers were fed 5 months in winter for the production of " baby beef ". The check lot received the following approximate daily ration: — shelled maize 10 lb., linseed meal 1.7 lb., immature maize and Kafir corn silage 10 lb. and alfalfa hay 4.5 lb. ; the others received some variant of this. A ration in which the maize was ground produced slightly greater gains and more finish than the check ration and the added profit more than offset the cost of grinding. A lot receiving cottonseed meal instead of linseed meal showed inferior finish, although the gains were only slightly decreased. Until the end of the third month the calves receiving cotton seed meal had gained more than any other lot and showed as much finish, but after that time cottonseed meal did not seem to stimulate the appetite in the same way as linseed meal, with the result that they would not eat as much feed and could not make the gains.

A lot receiving no silage but nearly doubling the alfalfa consumption of the check lot, made the least profit per calf of any lot, due partly to the difference in prices charged for alfalfa and silage, and partly to lower gains. A lot receiving neither silage nor supplement but over twice the check ration of alfalfa made the slowest gains of any lot and next to the lowest profits.

SHEEP AND GOATS

232 – Comparison between Rape and Bluegrass as Pasture for Fattening Lambs, in Kentucky, U. S. — Horlacher, L. F., in *Breeders Gazette*, Vol. LXXV, No. 26, p. 1508 and 1510 Chicago June 26, 1919.

In an experiment made at the Kentucky Experiment Station the author has compared rape and bluegrass (*Poa pratensis*) as forage crops for fattening lambs. The lambs sucked their mothers at night and morning ; during the day they were separated from the ewes and placed in the pasture ; they were also given half a pound of a mixture of oats and bran, in the proportion of 2 : 1 per head per day. The test lasted 42 days commencing

each on June 20 1918. One lot of 10 lambs was placed on an acre of bluegrass (which had not been previously pastured) ; their average initial live weight was 62.3 lb. ; they had an average daily gain in live weight of 0.3 lb. per head and they consumed 1,9lb. of grain per pound of gain.

Another lot of 10 lambs which was placed on an acre of Dwarf Essex rape, had a average initial weight of 59,4 lb ; the gain in live weight was 0,38 lb. per head daily ; this lot only required 1,6 lb. of grain to produce an increase of 1 lb of live weight and were in better condition and more appreciated on the market than the other lot.

During the first two weeks of the test, the lambs placed in the rape fields scarcely touched it,with the result that the lambs feeding on the bluegrass made almost double the gain in live weight that was made by those on rape. By the middle of July the pastures were getting dry : the bluegrass was still good for forage, but it was short and brown ; the rape was turning brown and yellow. At the end of the 4th week the lambs on rape had regained, in comparison with those on bluegrass, all that they had lost at the beginning and had taken the lead. The 5th week was constantly wet, which freshened the pastures, and the difference in favour of the rape was therefore not so marked as it would have been if the season had continued normal.

233 – **Goat and Sheep Rearing in Brazil.**— in *Bulletin Commercial de la Section des Affaires économiques et commerciales du Ministère des Relations extérieures*, No. 4, p. 19, Rio de Janeiro, October, 1918. (Contributed by Prof. DEOCLECIO DE CAMPOS, Delegate for to the International Institute of Agriculture).

Brazil is admirably suited for goat and sheep rearing. According to the estimate made in 1916, Brazil possesses 6 919 550 goats, distributed in the different States as follows :—

Alagoas	251 680	goats
Amazonas	7 640	»
Bahia	2 779 820	»
Ceará	464 740	»
Federal District	5 500	»
Espirito Santo	44 980	»
Goyaz	83 800	»
Maranhão	218 060	»
Matto Grosso	18 810	»
Minas Geraes	426 330	»
Pará	17 820	»
Parahyba	841 190	»
Paraná	67 770	»
Pernambuco	710 830	»
Piauhy	420 820	»
Rio de Janeiro	89 670	»
Rio Grande do Norte	352 000	»
Rio Grande do Sul	76 280	»
Santa Catharina	19 039	»
São Paulo	364 601	»
Sergipe	174 680	»
Territory of Acre	1 260	»
Total . . .	**6 919 550**	goats

Brazil occupies the second place in the list of countries which possess herds of goats, as may be seen from the following table :—

Union of South Africa	11 520 744	goats
Brazil.	**6 919 550**	»
Argentina	3 945 986	»
Algeria	3 772 424	»
Germany	3 438 290	»
Spain	3 116 238	»

Denmark	254 428	»
Belgium	185 373	»
Switzerland	171 635	»

Recently the Federal Government of Brazil, recognising that this branch of the industry was not by itself attaining the importance which the splendid natural conditions of the country could confer on it, promulgated a Decree which granted various favours specially to the breeders. The following are some of the provisions made :

Decree of February 27, 1917. — *Art.* 1. — The Government, with the aim of encouraging and developing sheep and goat breeding, will assist the States, Municipalities, Agricultural and Breeding Societies, Animal research stations and private individuals, when approved as perfectly suitable, by granting them the following favours :

a) Payment of a sum equivalent to ⅓ of the purchase price and of transport charges on breeding animals of the two species in question purchased abroad, up to a maximum of 25 animals of both sexes for each breeder.

b) Payment of the amount of 15 *paper milreis* (1) per animal imported and transport inside the country for breeding ewes up to 1000 head.

(1) 1 *paper milreis* = 1s. : 4 *d. at par.* (*Ed.*)

c) Pure-bred ewes or she-goats and rams for breeding, in excess of the number of head mentioned under *a*), will give the right to the benefits indicated in *b*) up to 1000 head in number. —

Art 2 — In order to obtain the above benefits the interested parties will have to prove :

1) That the extent of the land destined for rearing is in the proportion of 1 hectare to every 4 head.

2) That the land is dry and loamy.

3) That the fields are well cleared and no thorns liable to spoil the wool are to be found in them.

4) That they possess abundant and suitable fodder.

5) That they have a supply of pure running water.

6) That they are situated in a dry temperate climate.

7) That they have to hand suitable equipment, such as folds, diping troughs, places for storing and preparing wool.

8) That the regulations of the health authorities have been observed at the time of importation and that the animals imported are not under one year and a half or over three years of age.

Art. 3. — All regulations to the contrary are abrogated.

Foreign Trade. — In 1916, Brazil exported 326 sheep to the value of 4 651 *paper milreis* and in 1917, 126 to the value of 2 600 *paper milreis.*

In 1916 Brazil imported two goats, worth 253 *paper milreis*, and in 1917, 6 animals worth 729 *paper milreis.*

In 1916, the import of sheep was 1412 head valued at 187 091 *paper milreis*, and in 1917, 3 409 head valued at 247 059 *paper milreis.*

All these imported animals are pure stock for breeding.

234 – **The Breeding of "Kamcik" Pigs in Eastern Bulgaria.** — Gancev, G., in *Zemledielsko-Skotovodsto*, Year II, No. 7-8, pp. 154-158. Sofia, Sept.-Oct. 1919 (1). PIGS

With the exception of some unsystematic attempts at crossing with Berkshire, Yorkshire and Mongolitza breeds, all the pigs bred on a large scale in Bulgaria are of native origin. The "Balkanic" breed predominates but it contains local types differing slightly from one another according to the climatic, topographic and feeding conditions of each zone.

(1) In his work entitled *Le razze bovine e suine della Serbia* (Bologna, 1918) E. Mascheroni states that the improvement of native pigs in Bulgaria dates back to 1884. In that year English breeding animals, Yorkshires and Berkshires, began to be introduced, and the Government estabilshed piggeries with boars and sows at the schools of agriculture and at the stud stations. Only in 1906 were piggeries set up (at Kaja-Bouroum and Kula with a view to improving the native breed by crossing with the Mongolitza. The latter seems most suitable for crossing with the native Bulgarian pig, and it could not be otherwise, as pig breeding there is very different from that practised in England : the feed of Bulgarian pigs, and generally of all pigs in the Balkan peninsula, consists mainly of pasturage.

In Serbia, where the native pig belongs to the Balkan breed (the same as most of the pigs in Bulgaria), crossing with the Mongolitza pig has always given good results. The *Matchva* and the black *Morava* pig are improved by crossing with the Mongolitza. Even the Serbian half-wild mountain pigs (*Kostrechke* and *Konjari*) when cross bred with the Mongolitza give excellent progeny.

The Kamčík pig (Kamčüska Svinka) belongs to one of these types. In the valleys watered by the large and the small Kamčik, pig breeding has become a commercial affair. Every household rears from 5 to 20 of these animals and people owning up to 200 are not rare. The chief breeding centres are the villages of Smiedovo, Zlokuceni, Cenge, Novo-Selo, Koprii-Khoi, Goren Ciflik, Arnautlar, Staro-Oriekhovo, etc., situated in the districts of Varna, Prieslav and Pravadia (Eastern Bulgaria).

The Kamčik breed has some wild blood, as wild pigs, which are still fairly numerous in the more mountainous and out-of-the-way districts, sometimes mingle with herds of domestic pigs and stay there for a time. Also, new-born pigs have on either flank dark transversal markings, disappearing with age, which are characteristic of the Balkan wild pigs.

The Kamčik is of medium size : at one year old it is 60-70 cm. high and 0.80- 1 metre in length. It is black in colour, with white and black or yellowish spots. Well-fed specimens at 1 year weigh 80 to 100 kilograms, and with age may reach 150 kg. The pork is very good and the yield on the average is from 45 to 50 per cent.

For the greater part of the year the pigs live in the open in herds, mainly in the great oak forests where they find plenty of acorns, roots and excellent pasture. At 1 year they are fed for fattening, which lasts in all 30-40 days and consists for the first half of the time of acorns, and for the second half, of maize.

Beside so many excellent qualities from the local economic point of view, the native pigs of Bulgaria have the fault of being too small and too short. Hence the author urges the advisability of improvement by cross breeding. The Mongolitza breed would be suitable for this purpose.

235 - **Mineral Nutrients and Maize in Swine Feeding in Kansas U. S. A.** — *Kansas Agricultural Experiment Station Report for the Year* 1917, pp. 13-15. Manhattan, 1918 ; *Report for the y ear* 1918, p. 13. 1919.

In order to study the importance of mineral nutrients in swine feeding, 90 Duroc-Jersey pigs were divided into 15 lots and fed on maize, with various ash and protein supplements. Bone ash was a valuable addition to all rations tried, except those containing tankage, when it proved detrimental. A ration of maize meal and alfalfa pasture did not supply all the mineral required for young fattening pigs.

Six pregnant Duroc-Jersey sows, fed on maize only, and three fed on a similar low ash ration composed of ground maize, wheat gluten, and blood meal produced small litters of poorly developed pigs, half of which were dead in 30 days. The sows were generally in poor condition, and two died about 5 weeks after farrowing. Two control lots, comprising 3 sows each, were fed on a mixture of ground maize 70 parts, shorts 24 parts andt ankage 6 parts with or without extra mineral matter, and produced healthier pigs that grew more vigorously and showed a lower death rate.

Study of the influence of low-ash rations on pregnant sows was made in 1918 with 14 animals, 10 being survivors of the preceding year's work. Eight sows fed on ground maize alone either tap or distilled water pro-

uced 14 dead pigs and 39 living ones, of which only 6 lived for 2 months. hree sows fed on maize, maize gluten meal and blood meal produced 21 ead pigs and no living ones. Three sows fed on maize, shorts and tankage roduced 1 dead pig and 21 living ones, all still alive at weaning, 60 ays afterwards.

Study of the effect of protein and ash supplements to maize in the fat- ning ration was made with 66 Duroc-Jersey pigs weighing at the start bout 45 lb. a head and divided into lots of 6 each. The feeding methods re judged largely by the time necessary for the pigs to gain 150 lb.

Seven lots were fed on alfalfa pasture, and 4 in dry lots. Of the 7 for- ier, the 3 lots in which maize was the only concentrate took longest (104 to)7 days) to attain the desired weight. Additional ash had no apparent ifluence. The most rapid gains (97 days) were made by a lot given % of the concentrate as tankage and which had access to extra mineral utrients. A lot in which shorts and tankage (4 : 1) formed 20 % of the rain ration gained 150 lb. per head in 99 days. Two self-fed lots, one with iaize, shorts and tankage and the other with maize, tankage and additional sh, required 100 and 101 days respectively. Three of the lots not on asture received shorts and tankage (4 : 1) as supplement to maize. A feed- ig period of 112 days was required for two whose grain rations were 70 nd 60 % maize, respectively, and a period of 105 days for the other in hose ration the proportion of maize was gradually changed from 40) 80 per cent. The fourth lot not on pasture had free choice of maize, iorts and tankage and needed 104 days' feeding. Shorts and tankage ere consumed approximately in the proportion 8 : 1 and formed bout 30 % of the ration.

6 - **The Influence of Groundnuts and Rice Bran on the Quality of Pork: Experiments in Texas, U. S. A.** — Burk, L. B., *Texas Agricultural Experiment Station Bulletin* 224, pp. 5-13. 1 fig. College Station, January, 1918.

The purposes of this experiment were to determine : — 1) The value groundnuts as hog feed ; 2) the kind of pork that groundnuts will oduce ; 3) whether soft oily pork can be profitably hardened by feeding grain ration ; 4) whether or not hogs can be prevented from getting soft hen grazing on groundnuts by feeding a half grain ration ; 5) the kind of ork produced by milo maize and rice bran ; 6) the feeding value of the fferent rations.

The experiment involved 12 lots of 10 pigs each, averaging 107 lb. er head. The different lots were under observation at varying intervals, etween October 12, 1916 and January 19, 1917. For 20 days or more revious to the experimental periods all the hogs were fed on a balanced ain ration of milo maize chop and meat meal. All the lots except Nos. 1, 11 and 12 grazed on groundnuts or were fed on groundnuts in dry lots.

The hogs grazing on groundnuts produced an average of 158 lb. of pork er acre, the estimated yield of groundnuts being 19 bushels. The oundnut-fed hogs that were finished on grain were changed gradually om groundnuts in order to prevent the animals from going off feed. The

success of this method is indicated by the fact that every lot made its best gains during the week of the change. The lots on cottonseed meal and milo maize were fed for 80 days without any signs of cottonseed meal poisoning.

Some of the results of the feeding and slaughtering tests are given below.

At the beginning of the test two, hogs from a check lot were slaughtered and placed in a cooler temperature held at 32°F. After 24 hours they were firm. At the end of 40 days four hogs that had grazed with lot 8 on groundnuts were slaughtered and held at freezing temperature. These carcasses were soft and oily both after 24 and 48 hours of cooling. At the end of the experiments the hogs were sold to a packing house in Fort Worth, Texas, subject to a killing test. They were examined after being held in the coolers for 24 hours at from 32 to 38°. The results of this examination are given in the following table.

Effect of groundnuts and rice bran on pork.

Lot	Ration: Grazing crop	Ration: Grain		Daily gains per head: On peanuts	Daily gains per head: On dry lot	Feed per pound of gain	Shrinkage in shipping	Condition of carcass after 24 hours in cooler: Firm	Condition of carcass after 24 hours in cooler: Oily

(1) One pig removed, sick.

In addition to the slaughter test, melting point determinations were made by the station chemist of samples of fat taken from the leaf fat, shoulder and along the back of three hogs of each lot (1). The hogs fed

(1) See *R.*, Oct-Dec., 1919, No. 1200. (*Ed.*)

on groundnuts throughout the period and killing soft, showed a much lower melting point than those receiving a straight grain ration throughout and also a lower melting point than those fed on grain for 30 to 60 days after grazing on peanuts for 40 days. In practically every case the melting point test corroborated the test in the coolers. The hogs were valued at the beginning of the test at 7.5 cents per pound. They sold for 10.9 cents on the Fort Worth market. the soft or oily hogs being docked 1.5 cents per pound. In spite of high prices for feed and labour a profit was made on every lot except No. 1.

37 - **Alfalfa Meal for Fattening Pigs, in Iowa, U. S. A.** — EVVARD, J. M., in *The Breeder's Gazette*, Vol. 75, No. 16, p. 918. Chicago, April 17, 1919.

At the Iowa Agricultural Station two groups of pigs weighing 52 pounds at the beginning of the experiment shortly after weaning time were fed on grain and tankage from a self feeder, free-choice style. Group I, on a ration of shelled maize alone, reached 225 pounds weight in 115 days. Group II, on a mixture of ground maize and ground alfalfa, took 138 days to make the same weight, i. e. 20 % longer time. This group consumed less tankage than the first one, but the figures for the cost of the feeds per unit of grain show that 18.8 pounds of alfalfa and 32.8 pounds of maize equal 10.3 pounds of tankage. Thus, even excluding 23 days of labour,. the group fed on ground alfalfa showed to least advantage.

On the other hand, ground alfalfa gives excellent results as an addition to maize for pregnant gilts, which have to keep in good condition without fattening.

38 - **Castration Due to Feeding Cocks Exclusively on a Meat Diet.** — PÉZARD, A., in *Comptes rendus de l'Academie des Sciences*, Vol. XLXIX, No. 24, pp. 1177-1179. Paris, Dec. 15, 1919. POULTRY

In a series of experiments carried out between 1901 and 1906, F. HOUSSAY (1) studied the modifications produced in cocks and hens by an all-meat diet. Amongst the results obtained, this author found a diminution of sex dimorphism ; — progressive sterility, cocks losing their fighting instinct, hens acquiring spurs, etc.

Having established that sex characters depend on the genital glands, the author was led to investigate whether the facts observed by HOUSSAY were not connected with some modification of these glands, resulting from the kind of feeding. The modifications of sex dimorphism appearing in cocks fed on meat can be interpreted rationally by the work carried out by the author between 1910 and 1918.

The following are the conclusions arrived at from these investigations : —

The variations in sex dimorphism appearing in meat-fed cocks can no longer be attributed to the *direct* influence of the diet. The truth is that an exclusively meaty diet brings about a slow intoxication of the organism, to which the genital glands are especially sensitive and in consequence

(1) F. HOUSSAY, Variations expérimentales. Études sur 6 générations de poules carnivores (*Arch. de Zool. exp. et gen.* VI, 1907, pp. 137-332). (*Author's note*)

of which they may gradually become atrophied or not develop. Then, as a *secondary* effect there appear the well-known modifications which result from castration.

These results may serve as basis for an explanation of the neutralisation of worker bees, or better for the inverse transformation of a worker larva to a virtually fertile queen. In addition, they show that the response made by the organism to the suppression of the testes is unified whatever be the cause of this suppression (physiological, pathological or by operation).

Results of the same nature were obtained by SCHEPELMANN on geese (1906) (1) and by C. B. PAUL on rats (1906) (2). They give a glimpse at the generalisation of the facts connected with castration due to feeding.

BEE-KEEPING

239 - **Bee-Keeping and Honey Production in the United States.** — JONES, S. A., in *U. S. Department of Agriculture, Bulletin*, No. 685, pp. 61. Washington, June 20, 1918.

Statement and discussion of numerous statistical data relating to bee-keeping and honey production in the United States. A series of Tables gives for each State: the number of hives on farms, the percentage of total swarming in the various months, wintering (food and protection against cold), losses from disease and during wintering (causes and percentages), annual production of honey per colony, the total annual honey production, the form of honey produced, the colour of the honey, the disposal of the honey taken (domestic use or for market), the value of the export of American honey from 1911 to 1917, the import of honey into the United States from 1911 to 1917, the principal plants furnishing nectar and pollen with average dates of the beginning and end of flowering periods, the plants furnishing nectar and pollen for surplus honey (as distinct from that which the bees consume). In conclusion the geographical distribution of the more important honies and the conditions and prospects for the 1918 honey season are given.

Dealing only with the general averages for all the States we have the following figures:

INCREASE IN THE NUMBER OF COLONIES IN THE VARIOUS MONTHS OF THE SWARMING SEASON IN PERCENTAGES OF THE TOTAL ANNUAL INCREASE: March 3.5 %, April 16.4 %, May 25.1 %, June 36.2 %, July 14.8 %, August 4 %.

WINTERING. — Usual length of period between autumn and spring nectar flows: 5.8 months: longest period that the bees remain in the hives without a flight in an ordinary winter: — 1.5 months; amount of honey stored per colony at the commencement of the winter: — about 33 lb.; method of wintering: — in cellars 9.1 %; in double walled and packed hives, 9 %; packed or in cellar (not separated), 4.3 %; packed above, 2.5; wrappings of tar paper, etc., 0.9 %; straw covering and

(1) SCHEPELMANN,, Ueber die gestaltende Wirkung verschiedener Ernährung auf die Organen. der Gans (*Arch. f. Entw.*, Vol. XXI, 1900; Vol. XXIII, 1907). — (2) C. B. PAUL, On the Influence Excessive of Meat on the Male Reproductive Organs (*Journ. of Phys.*, Vol. XXXIV, 1906). (*Author's note*).

iscellaneous, 1 % ; total percentage of hives protected against cold, 5.8 % ; (in the southern States this precaution is not necessary).

Losses from disease in summer and winter. — Summer sses : — in 1915, 1.5 % of the colonies ; in 1916, 2.3 % ; in 1917, 3.5 % ; inter losses from all causes : — in the 4 winters of 1914-1915 to 1917 — 918, 12.6, 13.3, 10.1, and 18.7 respectively.

Annual honey production per colony. — Average for all States uring the quinquennial period 1913-1917, 41.6 lb.

Total production of honey in the United States (census of 1909) : 54 814 890 lb.

Form in which the honey is produced (percentages for the 4 years 914 to 1917, respectively). — Comb honey in sections : — 41.7, 40.0, 8.1, 37.9 % ; honey extracted by centrifugal machines, draining or ressing : — 42.1, 41.0, 43.8, 48.4 % ; comb honey more or less broken nd mixed with liquid honey (" bulk " or " chunk " honey) : — 16.2, 9.0, 18.1, 13.7 %.

Colour of the honey. — White 42.8 % ; light amber 29.5 % ; mber 17.1 % ; dark 10.6 %.

Exports and Imports. — For the fiscal years ending June 30, 1915, 916, 1917 and for the 6 months ending December 31, 1917 respectively here were the following values, in dollars, for *exports* : — 114 038, 52 487, 736 139, 1 254 887 ; and the following values, in dollars, for *mports* : — 255 274, 232 896, 455 167, 580 742.

Prior to the war the export was chiefly to Germany, during the war t was mainly to the United Kingdom. Imports came chiefly from in- ular possessions and from Central America. The quantities imported n the above-mentioned years and the average values were : — 303 965 21 224, 427 650, 227 092 gall. worth 41.1—44.1—67.7—112.7 cents per gall.

Plants furnishing nectar. — Percentage of the total honey ollected, furnished by the nectar of each kind of plant : Alfalfa, 7.7 % — lsike clover, 1.4, % ; *Melilotus* 6.2 % ; white and crimson clover, 19.6 % ; ruit tree flowers, 0.6 % ; lime 3.5 ; *Ilex opaca*, 1.1 % ; *Robinia* sp., 0.9 % ; *Diospyros virginica*, 0.5 % ; *Oxydendrum* sp., 1.6 % ; *Liriodendron* sp. 2.8 % ; *Nyssa* spp., 3.1 % ; other trees, 3.8 % ; *Ilex glabra*, 1.6 % ; *Rhus* 0.7 % ; other shrubs, 7.4 % ; *Rubus strigosus* and other species, 0.6 % ; other wild plants with small fruit, 0.6 % ; buckwheat, 2.9 % ; cotton, 4.0 % ; other plants cultivated in large crops, 1.7 % ; aster 1.4 % ; *Solidago virgaurea*, 2.1 % ; *Polygonum persicaria*, 2 % ; *Bidens* sp. and *Coreopsis* sp., 1.3 % ; other miscellaneous plants, 7.6 % — Blends : — Alfalfa + sweet clover, 1.4 % ; mixed clovers, 2.0 % ; clover + lime, 4 % ; other blends, 5.9 %.

SERICULTURE

242 – **The Partial Sterilisation of Mulberry Leaves in Silk-worm Feeding.** — Sacchi, R., in *Le Stazioni sperimentali agrarie italiane*, Vol. 52, Nos. 7-9, pp. 332-348. Modena, 1919.

The partial sterilisation of mulberry leave has been held up as a preventive against " flacherie ,, and as a means of obtaining more silk of better quality.

In order to test the value of this opinion, the author made a series of experiments, of which the ones described in the present study form the last part.

From previous experiments (1) it was concluded that :—

1) If the worms are fed on leaves washed with water or an aqueous solution of lysoform or " tachiol " (silver fluoride), far fewer leaves are consumed than if they had not been subjected to the treatment described.

2) Although silk worms fed on moist leaves eat less they weigh more than those fed on dry leaves.

3) The treatments described did not prevent the occurrence of a few sporadic cases of " flacherie ,, and emaciation.

4) The silk cover of cocoons from silk worms fed on partially sterilised leaves is heavier than that from silk worms fed on ordinary leaves. This increase in weight also occurs when the silk worms are fed on leaves sufficiently well washed with fresh or boiled spring water.

5) The feeding of silk worms with washed leaves has a favourable influence on the quality of the silk, particularly on the length, tenacity, and elasticity, as well as the weight of the reeled silk.

The greater weight of silk and the lower consumption of leaves, previously observed in 1906 by Prof. P. Bucci (*Bollettino della Società degli Agricoltori italiani*, No. 4, 1906), suggested that larvae fed on treated leaves would assimilate a greater quantity of nutritive principles from the leaf.

In order to check the accuracy of this idea, the author made a series of weighings and analyses of the leaves fed, of the leaf residues collected, and of the excreta collected. In this way the data grouped in the subjoined table, among others, were obtained.

The quantity of dry matter ingested and assimilated by the silk worms fed on washed or partly sterilised leaves is lower than in the case of untreated leaves. The surplus weight of larvae and cocoons is due to a higher content of water. When the cocoons are dried, those from silk worms fed on natural leaf weigh more than those from silk worms fed on washed or treated leaf.

These results agree with similar ones obtained by Verson (*Annuario della R. Stazione bacologica di Padova*, Vol. XXXIV, 1917). The author concludes that washing or partial sterilisation of the leaves prevents neither " flacherie " nor jaundice ; it does not assist in the production of silk but on the contrary appreciably diminishes it, and it does not affect the qualities of the silk. Consequently in the present state of things, the practice is not to be recommended.

(1) See *R.*, July, 1917, No. 655. (*Ed.*).

FARM ENGINEERING

AGRICULTURAL MACHINERY AND IMPLEMENTS

3 – **The Application of Electricity to Farm Work in Sweden.** — BJERKNES, K., in *Tidskrift for det Norske Landbruk*, Year XXVI, No 10, pp. 409-425 + 28 figs. Christiania, Oct., 1919.

ELECTRICAL PLANT FOR AGRICULTURE. — The greater part of the ectrical energy is produced in Sweden by hydro-electric stations, of which ıe three following supply considerable quantities of energy for agricul-ıral purposes : — Kungl. Vattenfaldstyrelsens (anlaeg), near Irolhättan ıd Älfkarleby ; the plant of the Electricity Company of Hemsjö, near arlshamn, and that of the South Sweden Electrical Society near Lagan,) the north of Malmö.

The main lines of the Vattenfaldstyrelse have an average tension of) 000 volts, which is reduced to 20 000 volts in the great transformers t the 2nd grade stations, and then to 1500-3000 volts in the 3rd grade ations. This current goes to the agricultural exploitations and serves irectly to drive the large motors, threshing machines, etc., while for light-ıg and for driving smaller motors the voltage is further reduced by uitable transformers to 220 volts and even less.

Each 3rd-grade station serves the country round about within a ra-ius of 3-4 kilometres, where the subscribers form a Distributing Society hich, construets local lines with its own capital.

To facilitate such undertakings the State grants long term loans on ood conditions from a special fund, called the Statens Kraftlaanefond.

The Distributing Societies unite to form District Societies or Cen-ral Societies, with their own engineers who carry out controls and im-rovements and are present in consultation, etc. These societies buy

material in common and wholesale, thus effecting considerable economy on cost prices and obtaining better results as to quality and type of material.

For the cost of electric current, the Vattenfaldstyrelse works a double scale of prices : 25 *ore* (0.345 fr. *at par*), per kilowatt-hour for lighting purposes, and 10 *ore* (0.139 fr. at par) for agricultural purposes. (In addition there is a supplement for the payment of interest and upkeep)

The Electricity Company of Hemsjö works in a similar manner ; only in this case, it is the Company itself which carries out the construction of the local lines, and it exacts in return a higher supplement from the users.

Use of Electric Power on Farmas. — As well as for lighting purposes, electric power serves to drive the following machinery : threshing mills, straw presses, winnowing machines, straw and fodder choppers kibblers, presses, elevators, cheese-making machines, milking machines, etc

Material and Instruments. — A series of notes accompanied by photographs serve to give an idea of the many and varied application of electricity to farm work. There is a detailed description of current transformed to 1500 volts, illustrated with plans, schemes and figures. There are also be mentioned : Small motors carried on hand barrows, a centrifugal pump installation, a very simple and practical elevator for bags, a fodder unloading and storing plant, and the " Comor " electric milking machine, the use of which ensures a remarkable saving of work and at the same time the most absolute cleaness and purity of the milk. These machines are attached to all the cows at the same time and the milking is done simultaneously and rapidly.

244 – **Tractor versus Horse Team.** — *The Pastoral Review*, Vol. XXIX, No. 10, p. 94. Melbourne, October 16, 1919.

The first agricultural tractor trial in New Zealand was held at Dar field, in Canterbury, in 1919.

Six tractors competed in a ploughing test, and four completed the plots, and it was the average work of the latter that was adopted as basis for comparison of costs, etc. The ground operated upon was lea land with a sparse covering of grass. The cost of a tractor was set down at £500, days worked per year 100, and the life of a tractor 500 days. The cost per acre at 5.37 acres per day was estimated at 14 *s.* 5 *d.* The cost for a year of a six-horse team, and an extra horse, was £630 6*s.*, the number of days worked per year 250, and an estimate of 5 acres ploughed equalled a cost of 10 *s.* 1 *d.* per acre, a difference of 4 *s.* 4 *d.* in favour of the horse team over a tractor. Therefore the tractor can successfully supply traction power for farm implements, but it cannot economically displace horses for constant work, on account of its higher cost of operation under present conditions.

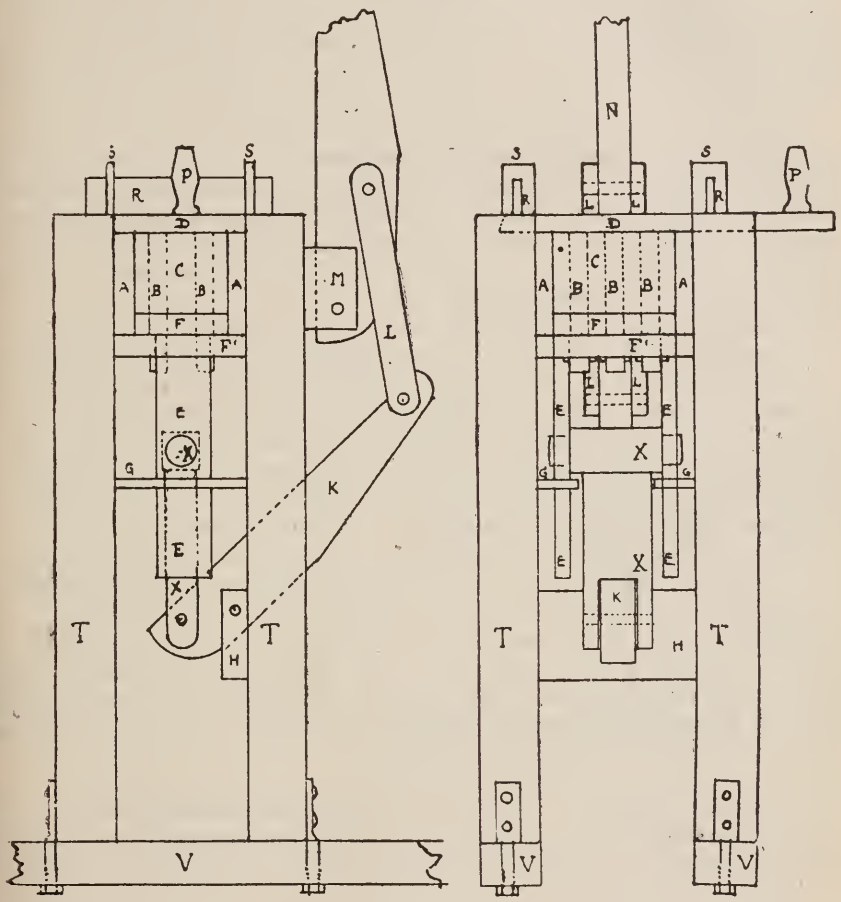
245 – **A Press for Fuel.** — Déjardin, L., in *Journal d'Agriculture pratique*, New Ser., Vol. XXXII, No. 45, pp. 410-911. Paris, Dec. 2, 1919,

This press is intended to utilise, in the form of perforated briquettes, coal and coke dust (1) and also all farm products that are thrown away

(1) See *R.*, Dec., 1918, No. 1416. (*Ed.*)

or are not considered usable as fuel, such as sawdust, dead leaves, paper, wheat and oat husk, etc.

For the purpose it is sufficient to mix the material to be pressed very thoroughly with a binding substance and to press the mixture. As, how-



Fuel press. — Vertical sections.

ever, it would not be appropriate to incur expense in order to utilise rubbish, the choice falls on very "fat,, clay soil an excellent binder which costs nothing and gives very good results when used in the proportion of 10 % to 12 % for coal or coke dust, and 15 % to 20 % for woody material, sawdust, dust from working machinery, husk, leaves, etc. When using paper, it is soaked some days in water, and the size glutinous content acts as a binder.

The following is a brief description of the press in question : —

A chamber *C*, supported on 4 posts *T*, and made to receive the mixture for pressing, is traversed by vertical rods *B*, fastened on to a fixed plate *F'* which are employed for perforating the briquettes. A mobile plate *F'* pierced with holes to let through the rods can be pushed from below upwards by the levers *K* and *N*, through two uprights *E*, guided by grooves *G*, and a connecting rod *X*. A cover *D* closes the top of the chamber *C* and is held solid by clamps *R* which are held in slots *S* bored in iron plates.

The method of working is simple : The mobile plate *F'* is lowered to the bottom of the chamber by raising the lever *N*. The cover *D* is drawn off by the handle *P*. The chamber is filled, the cover replaced and the lever *N* is forced down. Then the cover *D* is removed and, to free the briquette from the rods which have made the holes in it, the lever *N* is lowered to the ground. It remains only to lift off the briquette, by sliding it carefully, and setting to dry.

Pressure is exerted by means of two levers *K* and *N*, connected by 2 connecting rods *L*. The lever *K* acts directly on the rod *X*. The lever *N* acts on the lever *K*. If the arms of the lever *K* are in the ratio 1 : 4 and those of the lever *N* in the ratio 1 : 7, the rod *X* receives a force equal to $4 \times 7 = 28$ times the force exerted at the end of the lever *N*. If a man weighing 75 kg. hangs on to the end of the lever *N*, the matter enclosed in the chamber will undergo a pressure of $75 \times 28 = 2100$ k a pressure which may be increased by lengthening the lever *N*.

The measurements of the briquettes are 0.22 metre × 0.18 metre × 0.07 metre. When dry, they have a mean weight of 3.5 kg. if made of coal dust.

This press is easily made with hard rough sawn wood and bolts. There is no fitting and little iron work. Thus the farm staff which looks after the cart repairs could make it. Moreover, any hands which have not been discharged at the beginning of winter can be set to making briquettes when not otherwise employed.

246 – **Review of Patents.** — *Authorities :* GERMANY, *Landwirtschaftliche Maschinen und Geräte, Arterner Zeilschrift, Artern* (*Province of Saxe*). FOR BRITISH INDIA, CANADA, FRANCE, NEW ZEALAND, SWITZERLAND, UNITED KINGDOM, UNITED STATES, see *R.*, January 1920, No. 110.

TILLAGE MACHINES AND IMPLEMENTS. — *Germany :* 313040 Multi-furrow mechanically drawn plough with arrangement for ploughing on a curve, keeping an even width of furrow ; 313066 Motor plough with driving wheel adjustable on the axle ; 313136 Motor plough with engine self stoping in presence of obstacles ; 313139 Beam (multi-furrow plough) oscillating at too great resistance in soil ; 313179 Motor plough with 2 front wheels, one of which runs in furrow.

Canada : 193735 Harrows ; 193784 Rake tine.

United States : 1318296 Hay tedder ; 1320406 Reaper and binder.

Machines for Lifting Root Crops. — *United Kingdom :* 133157 Potato lifter and sorter.

Threshing and Winnowing Machines. — *United States :* 1317181 Screening machine ; 1317736 Maize huller ; 1320968 Huller.

Machines and Implements for the Transport, Preparation and Storage of Crops. — *Germany :* 313308 Root slicer.

Canada : 193882 Sheaf loader.

United States : 1314694 Cart with arrangement for loading and lifting shocks ; 1314815 Shock loader ; 1316081 Feeder for silo fodder chopper ; 1317882 Hay lifter ; 1318110 Fodder press ; 1318789 Hay-cock maker.

Switzerland : 83809 Straw-press feeder.

Traction of Agricultural Machinery. — *Germany :* 313283 Three-wheel tractor for ploughs and other cultivating implements, attached laterally to the back driving wheel.

Feeding and Housing Livestock. — *Canada :* 193788 Manger ; 193814 Water trough.

United States : 1318159 Pig oiler.

Apiculture. — *New Zealand :* 41374 Syrup container for bees.

Industries depending on Plant Products. — *Canada :* 193466 193542 Flax beating machines.

DAIRYING. — *Canada :* 193858-193859 Milking machines.
United States : 1316072 Milking machine.
New Zealand : 41313 Milk measuring apparatus ; 41978 Milking machine teat-cup.
United Kingdom : 132900 Cheese press.

RURAL ECONOMICS

247 – **Some Points Brought Out by Successive Surveys of the Same Farms (1912-1917) in Different Parts of the United States.** — HAWTHORNE, H. W. (Office of Farm Management), in *Journal of Farm Economics*, Vol. I, No. 1, pp. 24-37. Lancaster, Pa., June, 1919.

The Office of Farm Management of the United States Department of Agriculture, in addition to the annual statistical surveys conducted on a large number of agricultural areas in various parts of the United States, undertook several surveys in 7 different areas, with the object of studying from, the dynamic point of view the organisation and economical results of the areas under survey. The areas chosen were : —

1) The hill section of Ohio.
2) The dairy section of Wisconsin.
3) The corn belt in Indiana.
4) A trucking district of New Jersey.
5) An apple-growing section of the Shenandoah Valley in Virginia.
6) A trucking section of Florida.
7) A citrus fruit section in Florida.

The surveys in the first three areas have extended over a period of 5 years, those in the last four areas 2 or 3 years. The discussions in this paper centre around the first 3 areas, for each of which there are records for 5 years or longer. To facilitate the interpretation of the surveys a brief description of the areas follows : —

1) THE OHIO AREA. — This area in the hill country of Ohio is representative of much of the hill land drained by the Ohio river. The topography grades from rolling to very steep and is often rocky ; large unbroken fields being seldom found. The land is fairly productive and valued at $31 per acre The farms are from 4 to 9 miles from railroad points and the wagon roads are hilly and unimproved. The farms average around 160 acres, 22 % of which is unimproved (woodland and wasteland). Half the land is used for pasture and ¼ in growing crops, of which about one-fourth is in maize, one-fourth in wheat and small grains and one half in hay. Only 6 % of the maize raised was sold, also 35 % of the wheat and 16 % of the hay. Of the farm receipts, 15 % was from crops sales, 6 % from dairy products, 21 % from cattle, 14 % from sheep, 12 % from hogs and 17 % from poultry. Usable records include 25 farms for 7 successive years, but the data for the last year have not yet been tabulated.

2) THE WISCONSIN AREA. — This is an area typical of a considerable part of Wisconsin dairy region, The surface is rolling to hilly, the land is valued at $ 100 per acre, and only the main wagon roads are im-

proved. The farms average 148 acres, of which 11 % is unimproved; little more than one-third of the land is in pasture and a little more than one-half in crops. The crop land is divided almost equally among maize, the small grains and hay. Practically all of the crops grown in this area are fed on the farms, and the crop sales are but 3 % of the farm receipts, half of which come from the sale of dairy products or, in general $^2/_3$ from dairying and cattle sales, excluding hog sales, which represent over $^1/_4$ of the receipts. The records include 60 farms for 5 consecutive years.

3) The Indiana Area. — The area in Indiana is representative of much of the eastern part of the corn belt area. The surface is level to rolling. Much of the land is tile-drained, and it is valued at $ 185 per acre. The wagon roads are improved — most of them gravelled — and railroad points are readily accessible the whole year round. The farms average 127 acres and only 5 % of the land is unimproved. About $^1/_4$ of the land isin pasture and $^3/_4$ in crops. Nearly one-half of the crop land is in maize, one-third in' small grains (mainly oats) and the remainder in hay. A larger proportion of the crops produced in this area was sold from the farms than in either of the other areas. About 24 % of the maize, 80 % of the oats and 26 % of the hay was sold. Thirty five per cent of the farm receipts arose was from the sales of crops, 40 % from hogs and 13 % from cattle. In this area the records are from 100 farms for 5 successive years.

Two-fold object of the discussion. — The surveys further concern the variations in the economic results of the farms studied which took place during the pre-war period and the war period (1916-1917). The years 1912-1915 (inclusive) are taken for the pre-war period because the rapid rise in the prices of farm products in the United States caused by the war did not begin to be felt in agriculture until 1916. Hence in this presentation the war period includes the 1916 and 1917 crops. These data are all that is available as yet for tracing the effect of the war on American agriculture. Hence they are given with some detail.

Variations in labour income over the period 1912-1917. — The labour income variation from year to year in each of these areas is of fudamental interest (Table I).

Table I. — *Labour income variations for* 24 *farms in Ohio,* 60 *in Wisconsin and* 100 *in Indiana, from* 1912 *to* 1917 *inclusive.*

	1912	1913	1914	1915	1916	1917	Average of years before the war	Average of years during the war
Ohio	$ 512	$ 110	$ 190	$ 160	$ 324	$ 635	$ 153	$ 480
Wisconsin	—	214	56	68	626	1 075	113	850
Indiana	—	220	15	225	791	794	153	792

In the Ohio area the labour incomes for the years prior to the war ranged from $ 110 to $ 190. The year 1913 might be considered below normal for the following reasons: — It was the poorest wheat year, the yield

per acre being scarcely more than one half of the averages of 1912, 1914 and 1915, the quantity sold being less than one-half of the year of next lowest production and less than one-fifth of that of the year of highest production. The price was slightly lower than in 1912, 18 % lower than in 1914 and 16 % lower than in 1915. The apple crop was nearer a failure than any other year, the quantity sold being 17 % of that of the next poorest year and only 3 % of that of the best year. The price was from 5 to 30 % lower than in other years. The price of wool was 20 % lower than any other year.

Very low labour incomes are shown for the Wisconsin area in 1914 and 1915, which reflect the prices of dairy products and hogs for those years. In 1914, the prices received for dairy products were lower than any other year. They were slightly higher in 1915 but almost entirely overcome by the lower price of hogs.

The low labour income in the Indiana area in 1914 reflects the low maize yield, which was 10 bushels less per acre than in 1913 and 4 bushels less than in 1915, Hogs were lower in 1915 than any other year, but the crop sales were $ 278 more per farm than in 1914, oat sales were 30 % more than in 1914 and wheat sales almost double.

All the areas show higher labour incomes in 1916 than in the earlier years, and the Ohio and Wisconsin areas still higher in 1917, owing to combinations of higher price levels and increased production. In Indiana the labour income in 1917 scarcely exceeded that of 1916 due to a severe hail storm which swept diagonally across the area studied. If only the records of farms outside the strip affected were considered, the income for 70 would have shown as much increase over 1916 as in the other areas. The difference in actual value of the labour incomes for the years before the war and during the war is less than indicated, because the dollar had less purchasing value during the war than before.

VARIATIONS IN PERCENTAGE RETURN ON INVESTMENT OVER A PERIOD OF YEARS. — The percentage return on the investment after deducting the farmer's labour from the farm income is shown in Table II.

TABLE II. — *Percentage return on investment on* 25 *farms in Ohio,* 60 *in Wisconsin and* 100 *in Indiana from* 1912 *to* 1917 *inclusive.*

	1912	1913	1914	1915	1916	1917	Average of years before the war	Average of years during the war
Ohio	2.8 %	2.2 %	3.4 %	3.0 %	5.4 %	7.8 %	2.8 %	6.6 %
Wisconsin	—	3.9	2.9	2.9	5.8	7.7	3.2	6.8
Indiana	—	4.6	3.8	4.6	6.7	6.5	4.3	6.6

PERCENTAGE INCREASE IN RECEIPTS AND EXPENSES DURING THE WAR. — These are collected in Table III in the form of averages for the two-year period 1916-1917 and for these 2 years separately, for each area and for the 3 areas as a whole, and represent the percentages of increase in the averages for the period before the war, which includes the years 1912-1915.

TABLE III. — *Receipts and expenses on* 25 *farms in Ohio,* 60 *in Wisconsin and* 100 *in Indiana, during the war as percentages of those before the war.*

	Receipts			Expenses		
	Average of 1916 and 1917	1916	1917	Average of 1916 and 1917	1916	1917
Ohio	152 %	127 %	177 %	124 %	111 %	137 %
Wisconsin	155	136	174	129	116	143
Indiana	141	132	150	129	107	151
Average of 3 *areas*	**149**	**132**	**167**	**127**	**111**	**144**

Table III shows clearly that whereas the receipts rose by 49 % as compared with the pre-war period, the increase in expenses, on the average for the 3 areas, was only 27 %. The details of this phenomenon are given in the Table for the 2 years during the war and for the 3 areas separately. It may be deduced that if for 1916 the increase in expenses was only $^1/_3$ as great as the increase in receipts (average of the 3 areas), in 1917 it rose to $^2/_3$, and it may be judged that the tabulation of the 1918 data will show the increase in expenses to be equal to or in excess of the increase in receipts.

HOW FARMERS " SPEEDED-UP " DURING THE WAR. — In setting forth the data in Table IV an attempt has been made to show some of the ways in which the farmers in the areas studied contributed, with little if any additional labour available, to raise production in order to meet the food crisis brought about by the war.

TABLE IV. — *Intensity of production during the war on* 25 *farms in Ohio,* 60 *in Wisconsin and* 100 *in Indiana, as percentages compared with the pre-war period.*

	Before the war	During the war	% increase
The Ohio area.			
Months of labour	17.3	17.6	2
Acres in crops	42	46	9
Number of animal units	14.5	16.7	15
The Wisconsin area.			
Months of labour	22.2	23.0	4
Acres in crops	81	81	0
Number of animal units	16.1	18.2	13
The Indiana area.			
Months of labour	19.4	19.4	0
Acres in crops	40	46	15
Number of animal units	56	59	5

In the Ohio area, with an increase of only 2 % in the amount of labour, the crop area was increased 9 % and the amount of live stock 15 %. In the Wisconsin area with an increase of 4 % in the amount of labour, the crop acreage was maintained and the number of cows was increased by 13%. In the Indiana area with no increase in the amount of labour the maize acreage was increased 15 % and the number of hogs sold increased 5 %. It is readily seen that the farmers in each area, as a whole, increased the volume of their business. There were all sorts of variations on individual farms ; some show much greater increase than is indicated and some less.

The response came along the line of the prevailing type which is the best for the locality or the farmers. In the Ohio area where most of the crops are marketed through live stock, about one-half of the livestock increase was in cattle, which is the major enterprise of the area. In the Wisconsin area, a dairy section, the increase was in the number of cows. In Indiana, an area in the corn belt, where most of the maize is fed to hogs, there was no increase in the crop acreage, but the cropping became more intensive by decreasing the acreage in small grains and in hay, and increasing the maize acreage.

Annual output per man. — During the five-year period in the Ohio area, the quantities of the several farm products that these farmers put on the market annually per man has been worked out. These data are of special interest also, because this area is generally regarded as of much less importance agriculturally than either of the other areas ; yet this region includes a considerable proportion of the rural population and of the farm land in the United States, and in addition to what it produces for home consumption it makes a very appreciable contribution to the food and clothing supply of the nation. These data are summarised in Table V.

Table V. — *Annual output per man on 25 farms over a period of five years, 1912-1916, in Washington Country, Ohio.*

Stems	Quantities
Grain	2 822 pounds
Roughage	6 042 »
Potatoes	3 bushels
Apples	15 barrels
Eggs	486 dozen
Wool	247 pounds
Butter	124 »
Cattle (live weight)	1 850 »
Hogs (*id.*)	1 089 »
Sheep (*id.*)	600 »
Poultry (*id.*)	196 »
Equivalent of cattle, hogs, sheep and poultry in dressed meat	2 293 »

Variations in labour incomes of individual farmers. — Having shown the averages of farmers' labour incomes in the different areas, it is

very opportune to show also the annual variations on each farm, so as to bring out how far individual circumstances, closely connected with the farmer himself, affect the economic results of the work each year. In a final Table, 8 farmers in the Ohio area are placed for 6 successive years in the order which each occupied for labour income. On examining this Table, it is seen that the first 3 farmers showed great uniformity in standing for the 6 years in question. For each of these 3 farmers, the placing in rank is very close. On the other hand, for the rest of the farmers, there were greater variations of which it is important to investigate the causes. Thus farmer No. 4 descended from 1st rank which he occupied in 1914 to 8th in 1912 : farmer No. 5 who occupied 1st rank in 1915 fell to 18th in 1917 ; farmer No. 6 from 3rd rank in 1912 and 1914 to 18th in 1917 ; farmer No. 7 rose from 17th rank in 1914 to 1st in 1916, and farmer No. 8 who was only 5th in 1912, passed to 8th in 1913.

In, 1912 farmer No. 4, on account of sickness in the family, had to reduce his crop acreage by 12 %. In 1914 he was first in relative standing, having increased his poultry flock and gained on colts he bought and afterwards sold. In 1915, he was sixth in relative standing and his income was reduced by the loss of a cow and a horse. In 1916, he was fifth, and his wheat index was lower than in any other year. In 1912. farmer No. 5 was 4th and he ranked lower among his neighbours in wheat yield per acre than he usually did. In 1913, he was higher in wheat yield per acre than ordinarily, and his hogs fed out exceptionally well. In 1914, he dropped lowest in hay yield per acre. In 1916, he went below his ordinary standing in yield per acre of maize. In 1917 he showed greatest variation, through contracting steers for winter feeding on a cent-a-pound advance, while his neighbours who fed steers sold at an advance of 2 to 3 cents per pound over purchase price.

Number 6 dropped very low in 1916. He had a high priced team of work horses which went blind and he stood lower in rank in yield per acre of wheat than any other year.

Number 7, an excellent wheat grower, dropped to 13th in 1914 with his yield per acre of that crop, and he also ranked much lower in yield per acre of maize than ordinarily. In the latter years, however, he ranked better, through the higher price of wheat and wool he obtained on account of the time when he sold.

In 1913, No. 8 improved his position compared with 1912, by renting additional land and so having a larger crop acreage, and in succeeding years he showed a certain uniformity in results.

These illustrations are sufficient for establishing that there must be considerable variation in the incomes of individual farmers, even although the incomes of entire groups from year to year may be fairly constant. The other 17 farmers in the Ohio group show a similar amount of variation, and the Wisconsin and Indiana areas tell the same story.

SELECTING THE BEST FARMS IN AN AREA FROM A SINGLE YEAR'S STUDY. — In the earlier years of farm management it was held to be difficult to select the best farms in an area by observations on the general surroundings.

The following survey work confirms this, and the study of farms for a successive years shows that even after a single year's study there is considerable chance for error in selecting the best farmers, as determined by those with highest average labour incomes over periods of 5 or 6 years. Thus, taking 10 farms out of 100 with highest labour incomes, only 45 % of them will be amongst the 10 with highest average labour incomes over a five or six year period. On the other hand, selecting the 50 best farms, for any one year, there are 76 chances out of 100 that these 50 farms will be among the ones found best. Hence the importance of using wide groupings of farms when data for only one year are available.

INCREASING SIZE OF BUSINESS. — These surveys have emphasised the principle that an increase in the size of a farm does not always give an increase in the farmer's labour income, and that the ability and personal qualities of the farmer are the principal factor. Thus the first consideration for an 80-acre farmer in the corn belt who is making a lower labour income than his neighbours on farms of equal size, is to make good on his 80, rather than to get more land.

SINGLE YEARS' STUDIES VERSUS CONTINUED STUDIES. — The advantages of several-year studies do not in any way lessen those of single year surveys. In a study of the broad economic principles affecting an agricultural area or type of farming, the single year surveys probably have the greater value in that a larger number of farms can be studied than is practicable in continued work. There are, however, a number of well-recognised types of farming carried on in different sections of the country, such as the fruit-farming area of Virginia, the trucking districts of Florida, the citrus fruit districts, the dry-farming districts of the west, where it is nearly impossible to obtain results for one year that will give a true idea of conditions prevailing over a period of years ; only work carried on over a number of successive years gives such results. The continued work also has an added advantage over the one-year study of giving reliable information regarding the trend of agricultural development.

248 – **Economy in Stock Feeding.** — MARENGHI, E., in *Atti della R. Accademia dei Gergofili*, Year CLXVI, Nos. 2-3, pp. 86-97. Florence, August 25, 1919.

1) The use of fodders — economically speaking — should be based on obtaining from them *the greatest transformation value*.

2) Among the various means employed to attain this end, concerning the physico-mechanical preparation of the foods, the use of special condiments and the method of rationing the stock, the latter is of the greatest economic importance.

3) Rationing cannot be determined — case by case — according to absolute rules, on account of the many unknown quantities occurring in feeding phenomena in general.

The *ration factors* (dry matter minimum quantity of protein matter per unit of weight, nutritive ratio, etc.) are only *indices* of very uncertain practical value as compared with the multiplex circumstances under which they must be used.

It appears certain, however, that the most important *factor* in this uestion is the *nutritive value*, that is, the proportion of digestible protein to ernary substances (fats and non-nitrogenous extract reduced to the same hysiological value). The feeding value R is expressed analytically by the llowing formula:—

$$R = \frac{a}{2.44\ g + e}$$

here a, g and e indicate the percentage content of the fodder in digestile *albuminoids*, *fats* and *nitrogen-free extract* respectively. The quanty of fats is multiplied by the coefficient 2.44 to reduce it to the same approximate physiological value as the nitrogen-free extracts, granting that ne feeding power of each is in the same proportion (which is about 2.44) s the respective heats of combustion.

If the food in the ration is not in the most suitable proportion for the ind of animal, the age and the work done (rest, work, fattening, milk production, etc.), the substances which are ingested in excess — in comparison ith the others — are only partly utilised, according to this hypothesis as o their utilisation, in terms of the law of definite proportions. Mixtures are or the essential purpose of preventing these losses or reducing them to ne minimum.

The author observes in this connection that food mixtures, to conform o the economic point of view, should surpass the transformation value f their components ; that is, we should have: —

$(M_1 v_2 + M_2 v_2)$ $(M_1 + M_2) v_3$, where M_1 and M_2 denote the quanties of fodder, and v_1, v_2, and v_3 the respective transformation values of M_1, of M_2, and of the mixture $(M_1 + M_2)$.

The solution of the problem of mixtures (from the analytical point of iew) is very simple. It evidently requires that the *desired relation* be included among the *relations* of the foods to be mixed. The problem may e reduced to the following form :—

$$x = \frac{Ri_1 - a_1}{a_2 - Ri_2}$$

where R denotes the food value which the mixture is to have, a and a_2 dote the quantities of digestible albuminoids contained in the foods M_1 nd M_2 respectively ; i_1 and i_2 the sum of the fats and nitrogen-free xtracts reduced to the same physiological value, also contained in M_1 nd M_2.

4) With feeding stuffs there arises the economic problem of control nd valuation, as with fertilisers, the difference being that, under the ame of *digestible albuminoids*, there is a series of many heterogenous nirogenous substances which are not of the same physiological value. There re also *fats* and *nitrogen-free extracts*. Moreover, the market does not rovide *types of simple foods*, namely foods with a basis either of carboydrates or of fats or of albuminoids, which permit of determining the unit alue of each of the useful principles that have to be bought on the market

for the purpose of correcting the farm fodders which have an excessively wide food value.

This difficulty may be surmounted by admitting that there exists a certain *fixed relation* between the values of the substances indicated and that these are reducible to *units of the same value*, called *commercial units* by the use of a formula of the type : —

$$N = c + K_1 g + K_2 a.$$

where N = commercial units ; c, g, and a = content of the food in carbohydrates, fats and albuminoids respectively ; K_1 and K_2 = *unit value* of the fats and of the albuminoids respectively with regard to that of the carbohydrates considered equal to unity.

The relation between the values of the food principles has been previously determined according to physical and other considerations, and later on by means of a mathematical process, suggested by EMMERLING, based on the application of the Method of Least Squares.

The estimation of fats along with that of nitrogen-free extract, is carried out, in the first case, on the basis of the respective physiological value or in other words of the respective calorific values. The mean ratio which exists between the heat calories is 2.44 : 1, or, by rounding the figures slightly, 2.5 : 1. For albuminoids, the proportion between them and the nitrogen-free extract being, in the commonest normal rations, on the average 1 : 5 or 1 : 6, this ratio is simply considered valid, also for the respective commercial values.

The method followed by EMMERLING is the following: A certain number (fairly large) of foods is taken, their composition and market price being known. Now, supposing x, y and z are used to denote the unit value of the nitrogen-free extracts, the fats and the albuminoids, and granting that the market price (p) of each of the foods depends on the content of these principles (c, g, a), the following equations will be obtained : —

$$\begin{aligned} c_1 x + g_1 y + a_1 z &= p_1 \\ c_2 x + g_2 y + a_2 z &= p_2 \\ \cdots\cdots\cdots\cdots & \\ c_n x + g_n y + a_n z &= p_n. \end{aligned}$$

On solving the system of equations (more than determined) by the Method of Least Squares, the *most probable values* of x, y and z are obtained, and consequently the relation between them also is found, which in the present instance is wanted. In the author's opinion this method cannot be rigorously applied because, if the foods in question have some affinity — as, statistically speaking, should be the case in order that the Method of Least Squares may be applicable — an indeterminate system of equations is arrived at, which is therefore insoluble from the fact that the relation between the homologous coefficients of the unknown quantities is, within certain limits, constant. For foods having the characteristic of affinity, such as the *cake*, *hay*, *straw* and *food grain* classes, the application of the

ethod of Least Squares leads only to a system of equations of this form, hich is insoluble because indeterminate : —

$$x + [b + \varepsilon_1'\ ]\, y + [c + \varepsilon_2'\ ]\, z = [p + \varepsilon_3'\ ]$$
$$x + [b + \varepsilon_1''\ ]\, y + [c + \varepsilon_2''\ ]\, z = [p + \varepsilon_3''\ ]$$
$$x + [b + \varepsilon_1'''\ ]\, y + [c + \varepsilon_2'''\ ]\, z = [p + \varepsilon_3'''\ ]$$

here ε_1', ε_2', ε_3', ε_1'', ε_2'', ε_3'', ε_1''', ε_2''', ε'''... are relatively small iantities.

The author quotes as an example the data for the *cake* class : —

Kinds of cake	Digestible matter			Ratio between content of albminoids, fats and nitrogen-free extract
	Albumin-oids	Fats	nitrogen-free extract	
	%	%	%	
nseed cake	24.64	8.94	32.27	1 : 0.36 : 1.31
)lza "	25.23	7.54	23.74	1 : 0.30 : 0.90
oundnut	23.29	7.15	18.35	1 : 0.30 : 0.78
ndecorticated cotton	17.95	5.24	19.03	1 : 0.29 : 1.06
ape.	25.23	7.54	23.74	1 : 0.26 : 0.93
c. etc.	. . .	. . .	. . .	. . . . .

If, on the other hand, the foods themselves do not fulfil the condition affinity, the system is no longer indeterminate, it is true, but the values the unknown quantities derived from it are liable to very high probable rors, and on that account are not to be accepted as accurate.

The problem may, in the author's opinion, be solved by fixing the proortion on arbitrary criteria, because the results obtained — in practice — ary little, with the variation of the proportion itself (within the ordinary mits of variation. subordinate to the fact that albuminoids are of greater alue than fats, and fats, in turn, than nitrogen-free extract).

The author, by way of example, supposes that linseed cake has been urchased at 40 francs per quintal and that on a check analysis this cake not up to standard, as shown by the figures below :

Useful principles	Composition		
	Guaranteed	Found	Difference
	%	%	%
lbuminoids	22.10	18.00	−4.10
ats	9.40	8.60	−0.80
itrogen-free extract	30.50	30.00	−0.50

The variations in the *compensation* to which the buyer is entitled, by pplying the 5 different proportions adopted in the subjoined table, oscilte between 5.03 and 5.65 francs per quintal. Such a difference suggests hat, in commercial evaluations of feeding stuffs for stock, there is reason

to prefer the proportion 1 : 2 : 3 only because it is simpler to use and not for other causes.

Proportion adopted for the calculation	Commercial units			Price of commercial unit	Compensation
	Guaranteed	Found	Difference or units less		
	U	U'	$(U-U' = d)$	$(40 : U = p)$	$(d\ p)$
1 : 2 : 3	115.60	101.20	— 14.40	0.35	5.04
1 : 2 : 4	137.70	119.20	— 13.50	0.29	5.36
1 : 3 : 4	147.10	127.80	— 19.30	0.27	5,21
1 : 2 : 5	159.80	137.20	— 22 60	0.25	3.15
1 : 3 : 5	169.20	145.80	— 23.40	0.24	5.60

5) Another fundamental economic problem lies in the choice of the foods offered on the market.

The most suitable depends not only on the relative cost price but also on the transformation value at the farm.

By indicating as general terms : —

m_1, m_2	m a series of foods,
p_1, p_2	p_n their market price,
v_1, v_2	v the transformation value
c_1, c_2	c_n the relative suitableness

we shall have : —

$$c_1 = v_1 - p_1\ ;\quad c_2 = v_2 - p_2\ ;\ \ldots\quad c_n = v_n - p_n\ ;$$

and of all these foods, the one to be considered most suitable is that for which c is greatest.

The problems of economic suitability cannot be solved, in a general way, by basing the judgment of worth on the relative cost per commercial unit.

On the other hand, there are no sure data on the physiological value of foods with respect to the greatly varying conditions of consumption.

KELLNER attempted to treat the question by means of a long series of researches, especially on the feeding of cattle, but he succeeded in unravelling only part of the tangled skein.

He was able, indeed, to fix the conception of *valency* and express the physiological value of foods in *starch equivalents*, defining the latter as a quantity of fodder which gives the same yield in fat (250 gm.) as a kilogramme of starch, provided that, the fodder itself be consumed under certain conditions. Hence the idea of *valency* is an idea to which only a relative signification must be attributed.

KELLNER'S researches, however, have served to show how the same quantity of digestible feeding principles (according to the old analytical tables) can give rise to very different yields in terms of the nature of the foods, which he divides into two groups : *a*) those of *full value* : *b*) those of *least value*.

Feeding stuffs of *full value* are characterised by a *feeding power*, so to speak, proportional to their content in digestible *carbohydrates*, *fats* and *albuminoids*, such as oilcakes, meals, etc.; in short, all food substances entirely or almost lacking in fibre.

Fodders of *least value* have, on the other hand, a feeding power which never comes up to the theoretical power, that is, corresponding to the respective content in useful principles, and it is all the lower, the higher the fibre content is. In this group are straw, hay, etc.

The determination of *starch equivalents* of various foods is done in a very simple way by using KELLNER'S experimental data.

The fundamental *valencies* serving as basis for the calculation are the following: —

Useful principles	Starch equivalents
Albuminoids	0.94
Fats of common fodders (hay: straw, etc.)	1.91
Fats of non oily seeds	2.12
Fats of oilseeds	2.41
Carbohydrates	1.00

For fodders of *full value*, the calculation consists in multiplying the content of *albuminoids*, *fats*, etc., by the respective valency and in adding up the products obtained.

In the case of fodders of *least value* the same method is followed except for reducing the number of starch equivalents so found in terms of a particular *coefficient* which is proportional to the fibre content as established by the following figures:

Fibre content	Coefficient of reduction
Under 4 %	0.29
4-6 %	0.34
6-8 %	0.38
8-10 %	0.43
10-12 %	0.48
12-14	0.53
Over 14 %	0.58

KELLNER'S researches have enabled the data on the physiological value of foods to be expressed a little more precisely, but have not solved the problem from the economic point of view. It could not have been otherwise, given the method of the experiments, in which the value itself of the foods is determined by taking as the basis a certain ration, an *immutable* basis, considered as normal.

The yield obtained under these conditions cannot correspond to the effective curve of the phenomenon which, for evident reasons, conforms to the law of diminishing returns.

6) Hence the economic problem of livestock feeding still bristles with many difficulties which will be overcome, little by little, only by multiplying the researches so as to be able to trace, among other things, the *yield curves* of foods under the most usual conditions.

The actual elements to hand at present are confined to regulating — within certain limits, commercial transactions, but they do not help to solve the very important economic problems of the *choice* and *substitutes* of foods. Trying to use them for such a purpose may lead to very grave errors ; but farmers are generally by nature so shrewd and prudent that they very seldom allow themselves to be influenced by false doctrinal conceptions.

AGRICULTURAL INDUSTRIES

INDUSTRIES DEPENDING ON PLANT PRODUCTS

249 – **The Use of Artificial Cold to Accelerate the Maturing of Wines.** — MATHIEU, LOUIS (Director of the Oenological Station of Burgundy), in *Le Froid*, Year VII, Vol. VII, No. 6, pp. 133-135. Paris, June 1919.

In France the great inroads made in the stocks of old wines by consumption at the front during the war, and, the requirements of the whole world in fine wines are entailing the consumption of the recent vintages. Hence the necessity of accelerating the maturation of these wines without depending entirely on time for the requisite mellowness.

In order to obtain such rapid ageing without resorting to the use of processes requiring industrial plant, the author recommends the use of artificial cold, as refrigerating machinery provides at all seasons the action of cold, which brings about the clarification of the wine.

The freezing point of wine, which is between — 6° and — 8° C, may be reached without fear. In case of freezing, which is always partial, the wine must be allowed to liquefy again completely before racking, otherwise the wine from the frozen part would be much weaker than the first lot drawn off, and would have the qualities of watered wine (the separation of the ice can also be used to give concentration), but the wine would have to be racked before warming up again, or part of the substances made insoluble would redissolve.

To the physical action of the cold may also be added the influence of oxygenation at a low temperature. simply by aeration effected by injecting air with a pump. This aeration should be done after replacing the compressing plunger of the pump by a rounded tube of red copper bored with small holes on a horizontal diameter. Small sharp blows are given to the wine pump when empty, so as to send through, not a current of air, but small bubbles at the bottom of the cask. A large volume of air would remove alcohol and bouquet. What has to be got is a momentary saturation with oxygen of the mass of the wine. A few touches of the pump lasting 10-15 seconds are sufficient once or twice daily, as the oxygen in the interval is fixed by the oxidisable elements. According to the amount of oxidation the wine will stand and the agents causing it, these repeated operations accentuate the colour, bouquet and flavour more or less quickly as regards the quality of old wines, and experiments have shown that the

fineness thus obtained is much greater than at a high temperature, which justifies the reputation of frozen Burgundies.

If the wine had not finished fermenting and still contained active yeast, the effects of aeration on ageing would be very slight and might even be counteracted by a renewal of fermentation. Thus it is advisable with such wines to complete the fermentation, first re-activating the yeast by keeping in a warm place.

After racking on the spot the wines exposed to cold, as stated above, it may be beneficial in the case of wines destined to be bottled soon, to clarify them in the cellar in order to give them the right limpidity.

It will be clear that wines having a tendency to deteriorate (casser) must not be exposed to cold and especially aeration, because this would be the means of accelerating the consequences of their high degree of oxidisability.

It is interesting for makers to know the variations caused in the volume of wine by freezing, as these may give rise either to accidents or to losses of wine which might be attributed wrongly to other causes. The action of cold on wine causes a regular contraction in volume down to + 5° C,. then concentration quickly becomes very slight or even almost inappreciable down to the point of solidification. As soon as freezing begins a notable increase in volume is to be observed, which is all the greater as the volume of water solidified becomes more considerable and as the freezing proceeds.

There is another cause to which the increase in volume may be attributed viz., the presence of dissolved carbon dioxide in the wine, for example in the case of new wines before being drawn off their lees or still in process of fermentation. At the moment of freezing the dissolved gas is liberated in the form of bubbles, some of which are shut into the crystals of ice, and are all the greater the quicker solidification takes place. In one experiment the author obtained an apparent increase in volume of 14 % in a white wine still on the lees and slightly frothy at the time of sampling.

The necessary precautions should be taken to avoid loss by leakage through open bung-holes and cracks or through stoppers, especially with sparkling wines.

250 – **The Part Played by Iron in the "Casse Bleue" of Wines.** — PIÉDALLU, A., in *Comptes rendus de l'Academie des Sciences*, Vol. CLXIX, No. 23, pp. 1108-1109. Paris Dec. 8 1919.

The author had occasion to examine some wines that had been carried in tanks of unprotected sheet iron which is liable to be attacked by wines. as these are always acid. All the wines showed the same signs of "blue discolouration" (casse bleue), in this case a real synthetic alteration. Clear at first, they grew turbid on exposure to the air and deposited their colouring matter on the sides and bottom of the bottles, and at the same time the surface became covered with an iridescent film. This shows, as already observed by LAGATU, that blue discolouration can take place perfectly well without the help of diastases (without denying the existence of the latter elsewhere).

The author's observations prove : that all wines travelling, thus deteriorate ; that wines so affected get rid of their iron by oxidation (e. g., by

the addition of oxygenated water) ; that in order to preserve their marketable qualities, it is sufficient to place them in presence of a reducing agent, by simply drawing them off into casks well smoked with brimstone ; and that it is always better to avoid putting wines in contact with iron.

251 – **Manufacture and Chemical Composition of Concord Grape Juice.** — HARTMANN, B. G. and TOLMAN, L. M., in *U. S. Department of Agriculture, Bulletin* No. 656, pp. 26, 1 fig., Washington, May 8, 1918.

Much work has been done on the chemical composition of American grapes, but the available information is restricted principally to the acid and sugar content and is chiefly interesting to viticulturists. Hence the research reported in the Bulletin here summarised on the subject of the manufacture of the juice of the " Concord " grape (a variety of *Vitis Labrusca*) and the chemical composition of this commercial product.

The authors give advice regarding the handling and keeping of the grapes and describe in detail the different stages of the process of manufacture which includes : — Crushing and stemming; heating the crushed fruit ; pressing; sterilising and bottling the juice for storing; siphoning the juice; Bottling and pasteurising for sale.

A series of Tables shows the chemical compsition of the juice as prepared and after 4 months storage ; during this period 100 cc. of juice lose on the average 0.53 gm.of solids ; 0.02 gm. of sugar as invert before inversion ; 0.10 gm.of sugar as invert after inversion ; 0.51 gm. of non-sugar solids ; 0.13 gm.of total acid as tartaric ; 0.24 gm. of total tartaric acid free and combined ; 0.24 gm. of cream of tartar ; 0.12 gm of ash; 13.0 cc. of alkalinity soluble ash, N/10 acid ; 0.04 gm. of tannin and colouring matter. There is then a substantial decrease in solids during storage ; about half is due to the precipitation of cream of tartar and alkaline tartrates and the other half to the precipitation of pectin bodies and gums. There is a definite decrease in non-sugar solids, total acids and total tartaric acid ; on the other hand the sugar content is not materially altered.

Another series of tables gives detailed analyses of 104 examples of commercial juice from 6 different factories. They indicate that a well manufactured " Concord " grape juice contains less than 0.4 % of alcohol (it exceeds this percentage only when the pressing took too long) ; it contains no sucrose ; the polarisation of the inverted solution at 87.7° C is laevorotatory ; it contains about 0.5 gm. of free malic acid per 100 cc. ; it contains free tartaric acid and from 0.36 gm. to 0.79 gm. average 0.54 gm. of cream of tartar per 100 cc.

252 – **The Maple Sugar Industry in the Province of Quebec, Canada** (1). — VAILLANCOURT C., in *The Agricultural Gazette of Canada*, Vol. 6, No. 11 pp. 959-960. Ottawa, Nov. 1 1919.

The maple sugar industry has increased threefold during the last three years in the Province of Quebec. This is certainly due in part to increased

(1) The following articles have been published on the sugar maple in this *Review:* — January 1915, No. 46, GALLOIS, M., *Notes on the sugar maple.* ; February, 1915, No. 194, SOMERVILLE, W., *North American Sylviculture* ; April, 1916, No. 390, SHEDD, O. M., *Variations in the*

price of beet and cane sugars, but also largely to the sugar-making schools established by the Department of Agriculture in different parts of the province, and to the demonstrations given by special instructors in production centres. The three schools are at La Minerve (Labelle county), Beauceville (Beauce county) and St. Louise (L'Islet county). Modern methods of sugar and syrup making are taught in these schools. The courses last 10 to 15 days, and the Department pays the board of the students while they are in attendance at the sugar school.

A summary of the work done at these schools in 1919 is given below.

At La Minerve, 371 gallons of syrup were manufactured; the number of maples tapped was 3500 during the sugar season (March 24 to April 27).

At Beauceville, 14 230 gallons of sap were collected from 3500 maples and 3565 pounds of sugar manufactured (March 19 to April 24). There were 328 visitors and 27 pupils.

At St. Louise, 26 194 gallons of sap were collected from 5000 maples tapped (March 25 to April 27), and 210 pounds of sugar were made, 537 gallons of syrup and 100 pounds of "taffy" (tire). This school was visited by 458 persons ; 28 pupils took the course.

Five instructors gave 94 demonstrations in 18 counties throughout the province, with model apparatus for preparing sugar and syrup during the demonstration. The results of these demonstrations have been most effective, and it is said that about 75 % of the sugar manufactured in 1919 was of first quality.

In 1919, the total crop of sugar was less than in 1918. It would probably amount to 30 million pounds of sugar which, if valued at only 25 cents a pound, makes a total of 7 500 000 dollars. The crop of 1911 was only about 10 million pounds of maple sugar, which shows the great progress made by the industry during the last 10 years.

253 - **An Analytical Study of Spanish Olive Oil.** — FERNANDEZ, O. and BUSTAMANTE, F., in *Revista de la Real Academia de Ciencias exactas y fisicas y naturales de Madrid*, Vol. XVII, No. 7-9, pp. 281-286. Madrid, 1919.

The 33 samples of pure olive oil analysed by the authors at the "Instituto Nacional de Higiene de Alfonso XIII" were of the 1917 and 1918 crops, mostly from the province of Seville. The results obtained are summed up in the following table, which also gives, for purposes of comparison, the constants for Californian and Italian olive oil :—

mineral composition of the leaf and stem sap in American wild vines and sugar maple. ; September 1916, LEWIS T. G., *The forest species of Canada.* ; September 1917, No. 792, SAVOIE, F. V.,, *The Maple Sugar and Syrup Industry Schools of Quebec Province in Canada.*

Comparative table of the constants of olive oil from California, Italy, and Spain.

		Specific gravity	Refractive index	Iodine index	Saponification index	Acidity %	Specific temperature of reaction
Californian oil	maximum	0.9180	1.4718	89.3	194	8.21	109.7°
	minimum	0.9162	1.4703	78.5	78.3	0.20	94°
	average	0.9170	1.4713	85.3	85.3	1.20	101°
Italian oil	maximum	0.9180	1.4713	86.1	86.1	2.79	104°
	minimum	0.9103	1.4705	79.2	79.2	0.57	95°
	average	0.9155	1.4709	81.6	81.6	1.11	99°
Spanish oil	maximum	0.9180	1.4664	89.5	89.5	3.20	97.9°
	minimum	0.9128	1.4629	76.3	76.3	0.173	94°
	average	0.9154	1.4661	83.9	83.9	1.34	95.9°

254 - **The Lumbang-oil Industry in the Philippines.** — AQUILAR, R. H., in *The Philippine Journal of Science*, Vol. XIV, No. 3, pp. 275-285, Manila, March, 1919.

The manufacture of lumbang oil in the Philippine Islands has been so far in the hands of Chinese, who have made no attempt to improve the the methods of production and the oil which they express is dark in colour and of a disagreable odour.

But the oil industry generally in the Philippine Islands is undergoing a radical change, the manufacturers having a strong desire to increase the production and improve the quality of the product. Some of them, hitherto exclusively engaged in the manufacture of coconut oil, are now turning their attention to other oils, among which lumbang oil holds an important place. The object of the present paper is to discuss some of the more important points with a view to the best possible production of the oil.

There are two kinds of lumbang nuts worked in the Philippines for oil : — *Aleurites moluccana*, known as " Lumbang bato " (1), and *A. trisperma* (2) known as " Lumbang banucalag ". The former is more widely distributed and more abundant than the latter and is of greater industrial importance " Lumbang banucalat " is indeed almost unknown in the Manila market, and when the word " lumbang " is used alone it generally means " Lumbang bato ". The Chinese, who are the chief dealers in Lumbang oil are unwilling lo handle the " banucalag " variety because it is supposed that the nuts of that variety cause, on contact, skin eruptions ; but the author is of opinion that there is no foundation for that belief.

It would be interesting to develop the oil of " lumbang banucalag " as a separate industry, but meanwhile no doubt considerable profit would

(1) This is the " Bancoulier " or " Moluccan Walnut " Regarding *Aleurites* and their oils and the different " wood oils ", see *R.*, Apr., 1912, No. 662 ; *R.*, Dec. 1913, No. 1339. *R.*, Oct., 1914, No. 899 ; *R.*, May, 1917, No. 436 ; *R.*, July-Sept. 1919, *N.* 997 and *R.*, Oct.-Dec., 1919, No. 1237 (*Ed.*) — (2) Or *A. tritoba*. (*Ed.*)

be obtained by using the nuts of this species as well as those of *A. moluccana*. The increased production of these oils is important in view of the fact that a similar oil to Lumbang banucalag oil, Chinese wood oil, is highly appreciated in the United States by paint manufacturers. The fruits of both species of *Aleurites* mature and drop from the trees in June and July and the best time for gathering them is July-August. According to information obtained from the Chinese merchants the gathering of lumbang nuts could be much extended in Mindanao, more especially in the Davao Gulf district, where these nuts are known by the name "biao" and where large quantities are not collected. Hitherto there has been hesitation in placing capital in the lumbang oil industry because it was feared that insufficient nuts could be obtained to supply it regularly. But now, although the number of lumbang trees in the Philippines is not definitely known, it is certain that the production of nuts is abundant and quite sufficient to assure a profitable business to the oil industry.

The author deals with *Aleurites moluccana* and *A. trisperma*, their nuts and the oils obtained from them. He draws the following conclusion: — The lumbang oil industry, if properly developed, will be a profitable business.

It is much less desirable to purchase the kernels than the nuts from which to obtain the kernels, because oil from the kernels bought in the market is almost always of inferior quality to that obtained from freshly extracted kernels. No change took place in the oil content of whole uncracked nuts of lumbang bato stored for more than a year; but the content and quality of oil in Lumbang banucalag nuts are considerably reduced when they are stored for a similar time: the shell is insufficient to protect the oil in the kernel from oxidisation by the air and the kernels deteriorate very rapidly.

After expression, both kinds of oil can be kept satisfactorily in proper containers. It is therefore best, in the industrial season during which lumbang oil is expressed, to commence by using the nuts of *A. trisperma* and to store the nuts of *A. moluccana* to be dealt with when the former have been finished.

55 – **The Effect of Alkali Treatment on Cocoa.** — BLOOMBERG, E., in *U. S. Department of Agriculture, Bulletin* No. 666, pp. 20. Washington, May 9, 1918.

In the process of the manufacture of cocoa, the cocoa beans are roasted, the shells removed, the nibs crushed and the resultant product pressed so as to remove part of the cocoa butter. The pressed cake, ground and sifted, forms the cocoa of commerce. The removal of a part of the fat makes the colour of the cocoa much lighter. The manufacturers have tried, by various processes, to darken the colour of the cocoa so that it would more closely resemble chocolate. The commonest methods include the addition of alkalis or alkaline carbonates, ammonium carbonate or carbonate of magnesium. They are called "Dutch processes" from their place of origin. Under "alkali treatment" the author includes all such processes.

The investigations recorded in the present bulletin were under-

taken primarily with a view to ascertaining whether the alkali treatment rendered the cocoa more soluble, and what changes it caused. With this purpose in view the author made analyses of alkali treated and untreated cocoas and he determined the total ash, water-soluble and water-insoluble ash, and their alkalinity, and protein.

The results of the analyses show that the principal effect of the alkali treatment appears to be the increase in the colour of the aqueous solution. Treatment by alkali causes a decrease in the ash-free soluble matter and a slight increase in the amount of water-soluble protein ; this is, however, more then compensated for by a decrease in the solubility of non-nitrogenous substances which are normally soluble in water. A portion of the water-soluble protein of the cocoa treated with alkali appears to differ from the water-soluble protein in the untreated cocoa, since it is rendered insoluble when the water solution is made acid with 1% sulphuric acid. This difference between alkali treated and untreated cocoa may serve for detecting the alkali treatment.

Conclusions. — An alkali treated cocoa may be recognised:— By the high colour of the water solution ; by the presence of a water-soluble protein precipitable in 1 % sulphuric acid ; by the increase in the ash and alkalinity ratios. The assertion that alkali treatment increases the amount of cocoa soluble in water is absolutely without foundation.

256 – **Industrial uses for Cacao Shells.** — See No. 217 in this *Review*.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS

258 – **Meat from Madagascar** (1). — *Ministère des Colonies, Bulletin del'Agence Générale des Colonies* (formerly *Bulletin de l'Office Colonial*), Year XII, No. 142, pp. 601-602. Paris, Oct., 1919.

The cattle in Madagascar are generally estimated at 8000 head. local consumption amounts to 270 000 head at most ; during the 4 years 1914-1917 the five factories then working, delivered to the food departments 16 737 tons of frozen meat and 10 364 tons of preserved meat, representing a total of 215 224 out of the cattle existing on farms in the colony. This came to only 43 044 head per year, which figure, added to that of the local consumption, gives 313 000 animals, a quantity much below that which the Madagascan herds can yield annually.

Four of the factories are situated near the sea : -- Boanamary (Majunga), Tamatave, Antongombata, and Montagne d'Ambre, to the south of Diego Suarez Bay ; one is situated at Tananarive itself ; a sixth, which began to work in 1918 at Antsirabé in the Vahinankaratra on the plateaux, makes exclusively preserved pork. Diego and Tananarive make only preserved products, and Majunga makes preserved and frozen meat.

The production, which in 1914 came to 440 tons of frozen meat and 815 tons of preserved meat, had risen to 16 737 tons of frozen and 10 364 tons of preserved meat by 1917.

(1) See *R.*,fan., 1019, p. 1, and March, 1919, No, 274. (*Ed*).

These factories are supplied only from the herds in the north and centre. The south of the island, although very well off in cattle, has not yet any outlets for its production, and it appears certain that one or more factories could thrive there.

259 – **Experiments in Preserving Eggs in Italy.** — PASSERINI, M., in *Bollettino della Società italiana per lo studio dell'alimentazione*, Vol. I, No. 1-3, pp. 23-30. Florence, 1919.

AGRICULTURAL PRODUCTS; PRESERVING, PACKING, TRANSPORT, TRADE

From the results of a series of experiments conducted in 1918 at the Scandicci Agronomic Institute (Florence), the author concludes that : —

1) Eggs may be preserved dry for over 7 months, provided they have been taken very fresh, carefully washed, have had their shells lightly rubbed with fat (lard) containing 1 % of salicylic acid, and have been kept in a cool dry place. The loss in weight, due mostly to the evaporation of moisture through the shell, amounted to only 5 % in 231 days.

2) By wrapping each egg thus greased in oiled paper, the loss in weight may be reduced to less than 3 % in 231 days. In both these cases the eggs keep their taste and smell almost unaltered and the albumen remains liquid in the same way as eggs preserved in lime water.

3) Immersion in lime water gave excellent results ; with perfectly fresh eggs, carefully washed, and sufficiently pure lime, like that from statuary marble, this method is good for keeping eggs, in a cool place, for 14 months. The slight taste of lye which eggs preserved in ordinary lime water take on in the course of time probably depends, not on the penetration of small quantities of lime into the interior of the egg, but on impurities in the lime, especially alkaline hydrates, as this taste is not found in eggs preserved in sufficiently pure lime water. Some writers think that the liquefaction of the albumen is due to the passage of small quantities of calcium hydrate into the interior of the egg, but the author's experiments show that, even with dry preserving, this occurs. Hence it probably depends on a molecular change in the albumen in time and perhaps also on the beginning of hydrolysis of the albumen concerned.

Partial sterilisation at 60° C., before immersion in lime water did not give good results.

5) Dry-preserving of eggs previously heated to 60° C and., placed in closed vessels gave disastrous results, whether these eggs were or were not coated with fat or gelatin. The same result followed when the eggs were exposed to ether vapour. Probably better results would have been obtained by placing the eggs in containers sterilised by heat, but in order to keep the contents from further taint, difficulties would have been encountered which were too unsurmountable in practice.

260 – **The Prevention of Breakage of Eggs when Shipped in Car Lots.** — PENNINGTON, E., MACLEER, H. A., GREENLEE A. D., assisted by DAILEY, F. X. and ALBIN, H. C., in *U. S. Department of Agriculture Bulletin* No. 664, 31 pp. 8 Pl. 12 Figs. Washington, April, 25 1918.

These investigations were carried out during two seasons on the car lots of eggs sent from different parts of Texas and Minnesota in the eastern States over an average haul of 1200 miles, in order to determine the causes of damage to the eggs during transport.

When the following conditions were realised: — 1) eggs sent in car loads packed in good, well-made, standard cases with new fillers and flats, with properly placed and suitable cushions at top and bottom; 2) cases tightly stowed and efficiently braced; 3) cars handled in accordance with good railroad practice, especially when switching; the total damage referable to transit was less than 2 %.

The size of the egg influences its safety in transit. Eggs which were longer than the cells of the fillers showed 3.71 % damages. The eggs with lightly cracked or dented shells, but with membrane unbroken showed a transit damage of 2.88 % as compared with 1.77 % for eggs with sound shells. Applied to case lots of broken eggs, the increased liability to damage is noteworthy.

Egg cases must be standard, symmetrically made with 5 or preferably 6 cement coated nails at each corner of the sides and bottom and at the centre partition. While cottonwood, gum, and tupelo cases vary but little in strength, but the cottonwood has, on the whole, the greatest number of advantages.

Medium fillers or heavier ones should be used. It is absolutely necessary that the filler be perfectly new. Suitable cushions of excelsior, with a flat, should be placed on the top and bottom of the case. The quarter filler is strong enough and it forms an even cushion. Corrugated board on the top of the case affords practically the same protection as the excelsior cushion, provided it takes up the slack.

More damage occurs in the top layer of eggs than in the deeper layers of the case, and more in the ends than toward the centre.

When cars are buffed with straw at the bunkers there is a slight but clear rise in damage as the cases near the centre of the car. There is also a progressively increasing breakage in the rows as they progress from the middle line to the side of the car.

The location of layers is apparently immaterial. The load of eggs must be a solid unit in the car, fitting without play. This is the most important factor in avoiding damage in transit.

The amount of damage in properly loaded cars buffed with straw is slightly less than in the same cars buffed with wood. When the straw buffing is placed at the bunkers and extends from the top of the load to the floor of the car, at least 50 % of the refrigeration is lost. Braces nailed to the car seldom arrive in place. They cause much damage. Self-bracing of the load by means of suitable strips placed below the cases is most satisfactory. Cars having steel underframes show a slightly greater amount of damage than those with wooden underframes.

The shocks incident to ordinary freight train handling while running, seldom cause damage in well-stowed cars. The shocks incident to switching are sometimes destructive. More care should be exercised in switching cars containing eggs. While the haul in wagons or trucks between the railroad terminus and the warehouse or store may be responsible for some damaged eggs, the breakage is ordinarily not more than 1 cracked egg per case.

PLANT DISEASES

GENERAL INFORMATION

261 – **The Control of *Trogocarpus ballesterrii* a Hymenopteron Injurious to the Pistachio Tree, in Sicily, Italy** (1). — *R. Stazione sperimentale di Agrumicoltura e Frutticoltura, Acireale, Bollettino* 37, pp. 9-10. Acireale, 1919.

In view of the Decree dated September 28 1919 by which *Trogocarpus ballestrerii* (syn. *Megastigmus ballestrerii*), commonly known in the country as the Pistachio Worm, is entered amongst the parasites whose compulsory destruction may be ordered (2), and considering the damage caused by this chalcid fly to the yield of the pistachio (*Pistachia vera*) and the economic importance of this plant in districts where the crop is most extensively cultivated, the Minister of Agriculture issued the following Decree, dated October, 7 1919.

Art. 1. — Combative measures against *T. ballestrerii* are made compulsory in the communes of Caccamo, Ventimiglia, Petralia Sottana and Gangi, in the Province of Palermo; Vita, in the Province of Trapani; Alessandria della Rocca, Burgio, Canicatti, Casteltermini, Caltabellotta, Cattolica Eraclea, Favara, Licata, Lucca Sicula, Montevago, Raffadali, Ravanusa, S. Angelo Muscaro, S. Biagio Platani, S. Giovanni Gemini, S. Stefano Quisquina, Sciacca and Camarata, in the Province of Girgenti; Butera, Mazzarino, Pietraperzia and Riesi, in the Province of Caltanisetta; Bronte, in the Province of Catania, and Rosolini in the Province of Syracuse.

Art. 2. — In the above mentioned communes, proprietors or exploiting parties of pistachio plantations are obliged to destroy in spring all the female flowers of turpentine trees (*Pistachia Terebinthus*) in their plantations or near-by, within a radius of one kilometre.

Art. 3. — Proprietors of turpentine plants situated near pistachio plantations must allow the destruction of the female flowers of this plant by proprietors or exploiting parties of pistachio plantations, without the right to any indemnity or compensation.

Art. 4. — The burning of pistachio fruits attacked by the insect in question is compulsory, both in the case of fruits which fall before harvesting and those which are included in the harvest.

Art. 5. — Those failing to conform to this Order, will be liable to a fine of 200 lire per hectare of pistachio plantation owned or worked by them, ex-

(1) See *R.*, July, 1918, No. 831. (*Ed.*)

(2) See *R.*, Oct.-Dec., 1919, No. 1260. (*Ed.*)

cept for the provisions of Art. 22 of the law of June 26, 1913, No. 888, which defines the steps to be taken in order to foresee and combat plant diseases, approved by the Decree of the Lieutenant Governor of the Kingdom on March, 12 1916, No. 723 (1).

Art. 6. — The Prefects of the provinces concerned are charged with enforcing the present decree, through the district observatories of phytopathology, the mayors and the royal carabineers.

The present decree will be published in the leaflet of legal notices for the provinces concerned and on the notice boards of the communial town halls indicated in Art. 1.

DISEASES NOT DUE TO PARASITES OR UNKNOWN ORIGIN.

262 – **Investigations on the "Mosaic" Disease of the Potato in the United States.** — Schultz, E. S., Folsom, D. Hildebrandt F. M. and Hawkins L. A., in *Journal of Agricultural Research*, vol. XVII, No. 6, p. 247-274, 8 pl. Washington, D. C. Sept. 15, 1919.

The poato "mosaic" although more common and, apparently, particularly destructive in certain sections of the United States, is nevertheless widely distributed in the rest of North America.

The disease has a decidedly detrimental effect on the yield. The characteristic symptoms of the disease are noticeable on the aerial parts of the plant, especially on the foliage. These symptoms may be modified or obscured by differences in environment or variety. Tubers of diseased plants trasmit the disease. Grafting a healthy scion upon a diseased stock, or of a diseased scion upon a healthy stock, may result in the development of the disease in the healthy part.

"Mosaic" may be transmitted by transferring juice from a diseased plant to a healthy plant. The disease can also be transmitted bythe agency of aphids.

"Mosaic" apparently tends to increase the sugar content of the leaves and to reduce their starch content. "Hill selection" has not proved successful for maintaning healthy stock when practiced in fields in which there was a considerable number of plants attacked by "mosaic". On the other hand, pulling up the infected plants before the aphids became numerous was an effective method for checking the spread of the disease.

DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

GENERAL

263 – **Investigations on the "Crown Rust" of Oats (*Puccinia coronata*), in Iowa, United States.** — Melhus, I. E. and Durrell, L. W., in *Agricultural Experimen Station, Iowa State College of Agriculture and Mechanic Arts, Botany and Plant Patholog Section, Research Bulletin* No. 49, pp. 115-144, 6 fig. Ames, Iowa, 1919.

In certain years *Puccinia coronata* Corda, restricts the production o oats in Iowa in a marked manner. It is noticed that this rust show

(1) See: Int. Inst. of Agric. *Annuaire international de législation agricole*, 6th yea (1916), pp. 880-881. Rome, 1917. (*Ed.*)

itself epidemic one year while in the following year the disease is reduced to very small limits. Up to the present time the various factors which influence the growth, development and epidemiology of this rust had not been definitely studied.

From research carried out by the authors during 3 years it has been proved, firstly, that the minimum temperature for the germination of the uredospores of *P. coronata* is 1° C., the optimum temperature 17-22° C. and the maximum temperature 35° C. The optimum temperature for growth of the germ tube is 20° C. The germination of the uredospores produced in the greenhouse is variable. In some experiments less than 5 % of them germinated ; in others a germination percentage of 90 % was obtained. The average of the percentages for all the experiments at the optimum temperature was 21.9 %.

It is essential for the uredospores of *P. coronata* to be in direct contact with water in order to germinate. A saturated atmosphere does not furnish sufficient moisture for germination. Uredospores floating on a film of water germinate better than those immersed in water and for this reason heavier infection may be obtained when the uredospores are blown on to moistened plants than when they are applied in suspension in water.

Ordinary tap water used in the experiments carried out by the authors was found to be noticeably toxic to the germination of the uredospores. Vaseline and paraffin oil in contact with water act as stimulants to the germination of uredospores. Vaseline increased the percentage of germination by 23 % over the controls, while paraffin increased it by 70 %, under the conditions of the experiment. The environment in which the uredospores of *P. coronata* are produced, influences their germination to a certain degree. Uredospores borne on heavily infested seedlings do not germinate so well as those borne on plants approaching maturity. A still, humid atmosphere favours rapid maturation of the uredospores. Uredospores detached from the host plant and kept in a dry capsule at a temperature of from 13° to 20° C. showed increased germination after 6 or 7 days. The biologic form of " crown rust " which lives on oats, has as alternative hosts, *Rhamnus cathartiens* and *R. lanceolata*' which is one of the most widely distributed native species. *R. frangula, R. caroliniana* and *R. alnifolia,* according to the data collected, do not serve as hosts in the intermediate stage (aecidium) of the biologic form of " crown rust " which is found on oats.

R. lanceolata grows generally in the southern half of Iowa and in many localities the bushes are within a short distance of the oat fields.

R. cathartica is commonly used as an ornamental shrub on lawns and in public gardens. It bears annually the aecidium of crown rust and may well constitute one of the means of annually renewing infection.

There are in Iowa two native species of *Rhamnus* (*R. lanceolata* and *R. alnifolia*) and two introduced species (*R. cathartica* and *R. frangula*).

In the United States there are at least 10 native species of *Rhamnus*. However, it is only in a few cases that their relationship to crown rust of oats has yet been established.

264 - **Observations on the Perithecial Form of the "Oak Oidium" in Italy** (1). — PEGLION, V., in *Rendiconti delle sedute della Reale Accademia dei Lincei*, Classe di Scienze fisiche, matematiche e naturali, Vol. XXVIII, Nos. 5-8, pp. 197-198. Rome, 1919.

On October, 1919, the author observed the presence of numerous very small perithecia on the leaves of a pedunculate oak grown from seed, on which, as is usual, a strong growth of oidium was evident. The perithecia were scattered over the mycelial spots existing on the two faces of the blade, but especially on the upper one.

Investigations carried out immediately, near Bologna led to the discovery of a very great number of these fructifications on pedunculate and hairy oak leaves gathered in different localities.

According to the author, the ascophorous form observed by him seems to correspond to *Microsphaera quercina* (Schw.) Burr.

DISEASES OF VARIOUS CROPS

265 - **The Ascomycete *Excascus purpurescens* and the Deuteromycete *Septoria rhoina* causing "Leprosy" (or "Reddening") and "Smallpox" respectively of Sumac (*Rhus Coriaria*): Diseases New to Italy.** — 1) TRAVERSO, G. B., in *Le Stazioni sperimentali agrarie italiane*, Vol. LII, No. 5-6, pp. 213-226, 2 pl.: 2) LO PRIORE, G. and SCALIA, G., *ibid.*, pp. 227-237. Modena, 1919.

I. — In the month of May, 1915, the "Cattedra ambulante d'Agricoltura" of Girgenti (Sicily) notified the Royal Station of Plant Pathology at Rome, by sending some small branches of sumac (*Rhus Coriaria*) which were diseased, the presence of a mycosis attacking the anacardiacions family of plants in that province. Examination of material sent later and researches made on the spot by Prof. TRAVERSO in the following month of June, enabled the disease to be identified and recognised as new to Italy, although this appears not likely to assume great importance from the practical point of view.

The disease, named "leprosy" of the sumac by the author, has been found limited to the Campofranco territory (Commune of Castrofilippo) along the road from Castrofilippo to Naro. The diagnosis of the disease is the following: progressive withering and early drying up of the young branches, but particularly a brownish red colour of the leaves, which finally take on a purple colour with violet shades.

This coloration, which appears first as spots scattered more or less irregularly, sometimes spreads very rapidly to all the leaflets of a leaf; sometimes it affects only a small number of them and not unfrequently it keeps to only a portion of the leaflet, mostly round the base. In the latter case the appearance of the leaflets is very characteristic, as the violet-red portion is clearly separated, without appreciable shading off, from the healthy green part, with an extremely marked contrast.

(1) See *R.*, Nov., 1910, pp. 181-182; *R.*, Dec., 1910, pp. 357-404, 410; *R.*, March, 1911, No. 998; *R.*, April 1912, No. 1298; *R.*, June, 1911, Nos. 1892-1893; *R.*, March, Nos. 576-577; *R.*, April, 1912, No. 742; *R.*, May, 1912, No. 852; *R.*, June, 1912, No. 973; R., Dec., 1913, No. 1395; *R.*, Jan., 1914, No. 75; *R.*, Dec., 1914, No. 1184, *R.* May, 1916, No. 583; *R.*, May No. 494; *R.*, 1917, July, 1917, No. 682. (*Ed.*)

No particular deformation of the leaves is noticeable, except sometimes some slight swelling between the ribs; also the diseased leaves are more fleshy and thicker than the healthy ones. It often happens that sumac leaves, through purely physiological causes, take on a reddish colour which might be mistaken at first sight for the disease in question; but in this case the red colour is lighter and such as anyone familiar with the sumac could easily distinguish from the other phenomenon; and again, this coloration affects preferably the oldest leaves, and it is not accompanied by any thickening of the leaves.

The young branches affected with leprosy gradually turn brown and dry up, without the plant apparently suffering outwardly, so that the resulting damage amounts to no more than a more or less marked lowering of the yield.

Microscopic examination of the diseased leaves, in comparison with healthy leaves, immediately reveals a quite characteristic structural deformation which serves as a diagnosis of the disease even when the parasite that is the direct immediate cause is not in evidence; namely, greater compactness of the spongy mesophyll in the diseased leaves and, more striking, radial lengthening of the epidermal cells.

From investigations carried out, on sections of affected leaves, the author has concluded that the disease in question is caused. by *Exoascus purpurascens* (Robins) Sacc., a species observed hitherto only on *Rh. copallina* in the United States and less authentically on *Rh. pyroides* in South Africa. The fact of the discovery of this parasite in Sicily on *Rh. coriaria* is of remarkable importance, both as regards the novelty of the host and because this is the first time the fungus has ben reported not merely in Italy, but in Europe.

Should the leprosy eventually spread, the author believs that spraying with Bordeaux mixture adding molasses or some other substance to make the solution adhere better to the young leaves of the plant, will be effective.

Since his inspection at Girgenti, the author has observed in several of these sumac plantations another fungoid disease, more widespread than the preceding one but, like it, not constituting a danger, in its present state, to sumac crops. As an effect of this disease, which is also new to Italy, and which the author proposes to call "vaiolo" (smallpox) of the sumac, the diseased leaves turn slightly yellow and become covered with small spots of slightly variable appearance, according to the degree of development of the parasite causing them. Small brown-red points are first seen scattered in variable numbers between the secondary ribs of the leaflets. These points next enlarge, always keeping a more or less circular outline, and generally remain isolated. At the same time the central part of each spot becomes of a whitish colour, due to the tissues dying; thus there result small white spots surrounded by a relatively large browned marginal ring. Lastly there appear, in the form of small black points in the middle of the spots, the fructifications (pycnidia) of a fungus which the author, by means of microscopic and taxonomic examination, identifies

as *Septoria rhoina* (Berk and Curt). Sacc., a deuteromycete which hitherto has been found only in the United States and always on *Rh. Cotinus*.

II. — Under the same "leaf reddening" of the sumac Professors Lo Priore and Scalia describe the disease that Traverso described as "leprosy".

Lo Priore states that he studied this disease in 1907 in the west of Sicily; Scalia later observed it on the Ionian coast but, neither of these authors had published their observations.

According to Lo Priore and Scalia the disease becomes evident between May and June on the youngest twigs; when once it begins to spread it attacks the older branches. The infection mostly affects the terminal leaflets and the corresponding part of the rachis, and appears as a peculiar redness which follows the appearance of black spots on the under side, generally starting from the midrib and covering a large part of the leaflet. The blackening and then the shrinking of the common rachis causes the upper part of the leaf to fall off, and perhaps later the lower part. When the infection is early enough to involve all the buds, the growth of the plant suffers a sharp set back. Then two distinct phases may show up: — *a*) the plant withers and its aerial parts die; the underground parts seldom die, and then only partially; *b*) the plant replaces the dead shoots with new ones and manages to repair part of its losses, if the infection does not spread to other buds. Cases of reinfection are not few in rainy years and on cool ground; they may be found two or three times from the middle of May up to the end of June, and cease only when the hot weather of July comes. The spots on the common rachis may lengthen and leave a part of the rachis intact, in correspondence with which the leaflets remain on after the fall of the opposite ones. Often however, as the spots gain the other side of the rachis, the upper portion of the latter shrinks and falls, with the corresponding leaflets. Infection is completed, if its course is rapid, in 10 to 15 days. In its first stage it is often localised to a small number of leaflets which become red or even black in their lower parts, as well as the corresponding part of the common rachis. The apex of the leaflets themselves may remain intact, but soon withers in consequence of the perishing of the lower portion. The infection often starts on the common rachis and reaches the base of the leaflets across their articulation. Infection of the leaflets constantly starts from the midrib, which is the first to turn red; then it spreads irregularly to one of the two longitudinal halves of each leaflet. The leaves on a single branch may appear partly diseased and partly healthy. On the same leaf there may be infected leaflets and the rest perfectly normal. The infected surfaces of the leaves show a purple red colour, quite different from the green of the healthy leaves. This alteration is accompanied by a slight thickening of the leaf due to hypertrophy of the epidermal cells and of the mesophyll elements. Soon after, the infected leaves change their colour from dark purplish red to a more pinkish colour while the surface seems to be covered with a slight waxy layer. These changes show on full-grown leaves as well as on young leaves which have

ust come out of the buds. The leaflets dry up very rapidly, however, before differentiating. Long, linear spots also of brown-red colour are visible here and there on the petioles. Corresponding with these spots a ight depression may be seen, caused by the outside tissues being affected. On these organs the typical waxy covering mentioned above has never been noticed. It sometimes happens that all the leaves on a twig, still growing, dry up. The twig itself may die off without showing notable symptoms of alteration.

The structural study of the diseased organs at various stages of the progress of the disease led the authors to attribute the cause of sumac leaf-reddening to a species of *Exoascus* which they identify, while awaiting the results of later investigation, with *E. purpurascens* (Robins). Sacc., already referred to.

Comparative trials of treatment with sulphur, Bordeaux mixture and spraying with 2 % solution of iron sulphate carried out at Alcamo (province of Trapani, Sicily), have shown that Bordeaux mixture (Menozzi formula) is the most effective means of checking the disease.

266 – **Diseases of Lettuce and Passion flower new to Victoria, Australia.** — BRITTLEBANK, W. W., in *The Journal of the Department of Agriculture of Victoria*, Vol. XVII, Part 10, pp. 626-269, 2 fig. Melbourne Oct., 1919.

The present paper deals first with the appearance in Victoria of *Marssonia perforans* Ell. and Ev. first described in Ohio, United States, as cause of the lettuce disease known as " lettuce anthracnose " and which brings about the perforation of the majority of the leaves of the plant. So far as Australia is concerned, the disease was noticed in a market garden in a Melbourne suburb in which lettuce seed from the United States had been sown. Lettuces in the same garden grown from seed of a different origin were not attacked. The diseased plants were destroyed and as yet no fresh appearance of the disease has been noticed. Experiments have shown that spraying with Bordeaux mixture will hold the disease in check. Diseased plants should be pulled up and burnt.

In the spring of 1916, numerous stems of *Passiflora* were attacked by a serious disease. An examination than made, revealed that they were affected with *Botrytis cinerea* Pers., and by another disease due to a discomycete (*Sclerotinia* sp.)

In the case of *B. cinerea* it was noticed that the chief centre of infection was at the points where the stem was tied to the trellis wire which supported it. At these points the stem is often slightly damaged by the effect of rubbing and these slight wounds offer a ready opening for the fungus. The symptoms of attack in the case of the passion flower are similar to those of other plants attacked by *Botrytis*. Wilting and death of the part of the plant above the point of infection is rapid, and after death sclerotia were found under the loose bark and in the pith. Experiments in infection by placing the conidia (obtained from the sclerotia found internally and externally on infected plants) or fragments of the mycelium on slight punctures made purposely, produced prompt infection. No infection took

place when conidia or mycelium was placed in contact with unpunctured parts of the plant.

In its action the disease produced by *Sclerotinia* sp. is similar in appearance to that caused by *Botrytis* and might at first sight be mistaken for the latter. In the cultural experiments the sclerotia failed to produce ascophores. As had previously been observed in the case of *B. cinerea*, the mycelium placed in contact with sound tissues of the host plant did not cause any infection ; on the other hand it caused rapid injury and death when placed in contact with wounded tissues. It was noted that the point of attack was at ground level or slightly below it, or at the point where injuries are most likely to occur during cultivation. Sometimes, but not often, the disease was found at the forking of the stem close to the level of the ground. Both *B. cinerea* and *Sclerotinia* sp. have been largely held in check in gardens where their presence had been noticed, by cutting and burning the diseased parts of the host and subsequently carrying out repeated spraying with copper-soda sprays.

267 – ***Polyporus Tsugae* Injurious to *Tsuga canadensis*, in the United States.** — WEST ERDMAN, in *Mycologia*, Vol. XI, No. p5, p. 262-277. Lancaster, Pa., 1919.

For several years dead timber of *Tsuga canadensis* has, according to observations made in Pennsylvania, been destroyed by a peculiar rot which seemed to be constantly associated with the appearance of sporophores of *Polyporus Tsugae* (Murrill) Overholts.

The examination of a group of the conifer along the Raritan river near New Brunswick, in New Jersey, has enabled the author to prove that many of these trees were dead or dying from attacks of *P. Schweinitzii;* some of the trees bore sporophores of *P. abietinus*, but most of the trees which had died recently bore sporophores of *P. Tsugae*, sometimes in great abundance. Further research has revealed the presence in these standing trunks of the same rot observed in stumps and felled trunks of *T. canadensis* in Pennsylvania. *P. Tsugae* had been previously reported in the United States (Vermont, New Hampshire, Massachusetts, New York, New Jersey, Pennsylvania, Ohio, West Viriginia and North Carolina) occasionally on pine, and more frequently on standing or prostrate trunks, on stumps and exposed or nearly exposed roots of *T. canadensis*. Few stumps or dead trunks escape its attacks when it is present in a locality, and as its destructive action is very rapid, it constitutes a possible source of danger for stored timber of *T. canadensis*.

The existence of the rot can generally be detected, at least in the more advanced stages, by the presence of the sporophores of *P. Tsugae*.

The damage which this fungus causes in the wood, and which the author describes minutely, is characterised by the fact that it commences as a sapwood rot (though the heartwood is later attacked,) producing a porous condition with numerous white cracks in the spring wood, and black spots scattered through the whole rotted part.

WEEDS AND PARASITIC FLOWERING PLANTS.

8 – *Cuscuta suaveolens* on the Onion, Carrot and other Plants in Wales, Great Britain. — *The Journal of the Board of Agriculture*, Vol XXVI, No. 8, pp. 836-837, 1 pl. London, Nov., 1919.

The presence of a species of *Cuscuta* had been noted in 10 separate lotments in the Cardiff district, and although onions were chiefly attacked ıe parasite was also found on carrots, parsnips, turnips, bird's foot trefoil, ıdwort, white clover and several grasses.

A flowering specimen of this dodder was examined at the Royal Boıic Gardens, Kew, and recognised as being *Cuscuta suaveolens* Ser. (known so under the names *C. racemosa* Mart, and *C. chiliana* Engelm.), a native Chili but frequently recorded as an alien in different parts of Europe ıd America (outside Chili). It is clearly allied to *C. Gronovii* Wild., ıe common American dodder, which seems indifferent as to its hosts; ıe latter has not been recorded wild in Great Britain, but is sometimes ıltivated in botanic gardens.

It was at first considered possible that *C. suaveolens* had been introıced in onion seed from America and it even seemed likely that the appearnce of the parasite in the Cardiff district might be due to clover seed from ıili. But later, two samples of carrot seed reached the Seed Testing Station which seeds of *C. suaveolens* were found; it is believed that these samples e of French origin.

9 – Mistletoe Observed on the Chestnut, in Switzerland. — MOREILLON, M., in *Journal forestier suisse*, Year LXX, Nos. 9-10, pp. 164-165. Berne, Sept.-Oct., 1919.

In November, 1918, the author found good tufts of *Viscum album* L. ı *Aesculus Hippocastanum* L., in a park in the Canton of Vaud, at an titude of 508 metres.

10 – *Sorghum halepense* as a Weed. — See No. 202 in this *Review*.

INJURIOUS INSECTS AND OTHER LOWER ANIMALS

11 – South Indian *Coccidae*. — RAMAKRISHNA AYYAR, T. V., in *Agricultural Research Institute, Pusa, Bulletin* No. 87, pp. 1-50, 6 fig., 16 pl. Calcutta, 1919. GENERAL

So far the *Coccidae* have not been sufficiently studied in South dia. The author thought that it was not without interest, not only r systematic entomologists but also for planters, arboriculturists, rticulturists and nurserymen, to enumerate all the species of Coccidae far recorded in South India, with special reference to those which have me economic importance. As far as possible he has avoided, both in the xt and in the illustrations, all minute structural details or technicalities garding these insects. Out of 129 species recorded in the paper only had been previously recorded from South India. The first record an insect of this family for South India was made in 1790 and the ost recent was in 1911. Of the remaining 89 species, 18 are new to

science, the others are recorded for the first time from South India and some are new to India as a whole. There is hardly any doubt that a few of them are of foreign origin and must have been introduced into India through nursery stock, fruits, seeds, bulbs, etc.

The great majority of the species recorded in the paper were collected in the plains of Southern India, chiefly in and around the Coimbatore Agricultural College, mainly by the author himself.

RESISTANT PLANTS

272 - **A New Variety of Wheat Resistant to Attacks of the Rhynchote *Cicadula sexnotata* (= *Jassus sexnotata*) in Sweden.** — See No. 192 in this *Review*.

MEANS OF PREVENTION AND CONTROL

273 - ***Leucopis nigricornis*, a Dipteron Parasitic on Coccids and Aphids.** — SCHUMACHER F., in *Zeitschrift für wissenschaftliche Insektenbiologie*, Vol. XIV, No. 11-12, pp. 304-306. Berlin, July 15, 1919.

Leucopis nigricornis is of notable importance as a parasite on coccids and aphids. Certain coccids are very largely attacked by the larvae of this dipteron. According to direct observation and bibliographic investigation done by the author, the parasite in question has up till now been found on the following hosts: —

1) Cocids: = *Eriopeltis lichtensteini* Sign. (Germany); *E. festucae* Fonsc. (Germany); *E. coloradensis* Cock. (United States); *Pulvinaria innumerabilis* Rathv. (United States); *P. acericola* Walsh. and Riley (United States); *P. floccifera* Westw. (Italy); *P. betulae* L. (Germany); *Eriococcus spurius* Mod. (Germany); *Lepidosaphes ulmi* L. (United States); *Chionaspis americana* Johns. (United States); *Ch. pinifoliae* Fitch. (United States); *Ch. ortholobis* Comst. (United States).

2) Aphids: *Aphis cephalanti* Thom — (United States); *A. gossypii* Glov. (United States); *Aphis* sp. (United States); *Pemphigus bursarius* L. (France); *P. transversus* (United States); *Macrosiphum avenæ* F. (United States); *M. sanborni* (Hawaii).

274 - **The Influence of Temperature and Other Physical Agencies on the Insecticidal Properties of Chloropicrin** (1). — BERTRAND G., BROCQ-ROUSSEAU and DASSONVILLE, in *Comptes rendus des séances de l'Académie des Sciences*, 2nd Half year, 1919, Vol. CLXIX, No. 22 (Dec. 1, 1919), pp. 1059-1061. Paris, 1919.

According to the place and climatic conditions, the activity of chloropicrin when used as a parasiticide is liable to be affected by the temperature and degree of moisture in the air. The authors have studied these circumstances and also the possible influence of light. Their experiments were mainly concerned with weevils, but were extended to other insects.

These investigations have demonstrated that in the use of chloropicrin against insects there is no need to trouble about the influence of light or shade or of the degree of humidity in the air, as these circumstances are without effect. On the other hand, temperature, very materially increases the speed of action of the insecticidal vapour as in the case of chemical

(1) See *R.*, Jan., 1920, No. 148. (*Ed.*)

reactions. Hence in practice it is very important to raise, where possible the temperature of the places where chloropicrin is being used for the destruction of insects.

275 - ***Heliothrips rubrocinctus*, a Thysanopteron Injurious to Cacao, in the Island of St. Thomas, Gulf of Guinea.** — *Boletim do Centro Colonial*, Year XI, Nos. 1-3. pp. 7-8. Lisbon, 1919.

Heliothrips rubrocinctus recently caused serious damage to some cacao plantations in the island of St. Thomas, where, up to the present, attacks of this insect have always been of limited intensity.

Experiments in the prevention and control of this insect bring out the effectiveness of spraying with the following mixture: —

Tar	2.8 gm.
Palm oil	4.6 gm.
Wood ash	4.6 gm.
Water	100 litres.

276 - **Diseases and Pests of the Tea Plant in Java.** — See No. 209 in this *Review*.

277 - **The "Lucerne Grub" (*Colaspidema atrum*) Injurious to Vegetable and Garden Plants, in France** (1). — MURATET, H., in *Comptes rendus des séances de l'Académie d'Agriculture de France*, Vol. V, No. 38, (Dec. 10 1919), pp. 970-972. Paris, 1919.

Besides the considerable ravages it occasions in fields of lucerne, *Colaspidema atrum* may cause appreciable damage in gardens and vegetable plots.

On June 26, the author noticed that the larvae of this coleopteron had overrun a garden situated at Blagnac, near Toulouse. They were found in large numbers on several plants which they had partly eaten, especially on the leaves and stems of potatoes, beans, parsley and on marguerite heads. The author then collected some of these larvae and fed them on the plants just named. He found that they attack preferably first the outer flowers of the marguerite (the tubular flowers in the centre remain intact), then leaves of beans, which were almost entirely destroyed, then parsley, only the stalks of which were devoured, the leaf blades remaining untouched. Finally, leaves of potatoes were least attacked.

The garden was between two fields of lucerne and this invasion of *C. atrum* took place after the young shoots of the second crop of lucerne in these fields had been mostly eaten up. It is therefore probable that the "grubs" had emigrated to the garden because their usual food had run short.

To reach the garden the grubs had to cross a vine but they had not attacked it. The author tried also to feed them on vine leaves, but without success.

278 – **The Coccid *Icerya purchasi* and the Coleopteron *Novius cardinalis*, its Natural Enemy, in their Relations with the Leguminosae *Genista aethnensis* and *Spartium junceum*, in Sicily, Italy.** — SAVASTANO, L., in *R. Stazione sperimentale di Agrumicoltura, Acireale, Bollettino* 37, pp. 1-4. Acireale, 1919.

For some years the author had oberved on the hills in the district east of Etna that specimens of *Icerya purchasi* on plants of *Genista aethnensis* were not destroyed by *Novius cardinalis*, but the coccid grew so fast on the host that it sometimes killed the plant. Further investigations revealed, at least so far, the absolute absence of larvae of *Novius* and pupa cases on numerous plants of this leguminous plant examined at various places on the east-coast side of the Etna district. On the other hand, on specimens of *Rhamnus Alaternus* and of *Rh. buxifolius* situated sometimes near or in immediate contact with plants of *G. aethnensis* there was noticed the presence of larvae and pupae of *Novius*. On making a comparative study, on one hand of citrus fruits and other plants almost free of the insect, and on the other hand samples of *G. althnensis* affected with parasites, it was found that the larvae of *Novius* usually attach themselves to the lower side of the leaves of an evergreen species, and sometimes also to the upper surface, provided they can live shaded from the sun. Consequently, the insect does not deposit its eggs on individuals of the *Icerya* existing on *G. althnensis*, because its larvae, on account of the particular conformation of the host plant, are exposed on it to the sun's rays. The mature *Novius* feed only on some *Icerya* on the leguminous plant in question and then deposit their eggs in coccids situated on neighbouring plants wtih large leaves or tufted foliage. The host coccids of *G. aethnensis* being only partly eaten up by the coleopteron, surpass the latter in development and thus succeed, in becoming numerous parasites and drying up the plant, on the death of which most of the *Icerya* then die off, except some which emigrate in time.

Before making these discoveries, the author was informed of an intense spread of coccids on rushes (*Spartium junceum*), on the hills in the east Messina district. No pupa or slough of *Novius* has been found on any specimen of rush examined, ast his plant has a conformation identical with that of *G. aethnensis*.

From the above observations it may be deduced that the coleopteron shows its weak side, since on the two leguminous plants mentioned the *Icerya* multiplies with impunity.

On the basis of a summary examination, it may be taken that the coccid is commoner in the hilly coastal district from Messina to Catania, where the damage is of slight importance. In order to prevent its spread in the middle and higher districts — which would lead to the faling off of a forest product very remunerative to these districts, where firewood and small timber is insufficient for requirements – it is desirable to see to the destruction, in the coastal zone, of the host plants of the coccids here mentioned.

279 - ***Psyche graminella*, a Macrolepidopteron Occasionally Injurious to Vines, in Switzerland.** — FAES, H., in *La Terre Vaudoise*, Year XI, No. 49, pp. 435-437, fig. 1. Lausanne, Dec. 6, 1919.

On May 15, 1919, the author received from Sion (Valais) a package of cases containing caterpillars of the *Psyche graminella*, with a statement that the para ite was attacking part of a vineyard on the Vasère hills. In the vineyard in question, one of the warmest and best situated in the district, the shoots were devoured wholly or in part by the caterpillar, over an area of about 400 square metres.

The author advises, to combat this parasite, besides collecting the cases, the use of copper aceto-arsenite, at the rate of 400 grammes per hectolitre of Bordeaux mixture, which gives very satisfactory results.

The caterpillar was described in 1907 by VALÉRY MAYET as occasionally attacking vines ; up to the present it has never been reported in Swiss vineyards, at least within the author's knowledge.

After describing the morphological and biological observations made on numerous specimens reared in the laboratory, the author adds that it is not to be feared that this insect will ever do serious damage as a parasite in Swiss vineyards. It will remain an occasional pest, attacking the young leaves only when intense drought kills or greatly hardens grass culms, which form its usual food.

280 - ***Cosmopolites sordidus*, a Beetle Injurious to Bananas in Australia.** — FROGGATT, W., W. in *the Agricultural Gazette of New South Wales*, Vol XXX, part II, pp. 815-818, 1 fig. 1 pl., Sydney, Nov., 1919.

Cosmopolites sordidus Germ. was first recorded, for New South Wales, in a banana plantation near Stoker's Siding in the river Tweed district. The district at present infested with the beetle appears to be the Condong Range, where there are a number of plantations more or less seriously attacked. It is not unlikely that the beetle will also be found sporadically in other districts. It has not been possible to determine how the insect reached Condong, but it was probably introduced with young banana plants from Redland Bay, Queensland, before the presence of the pest had been reported in the latter district and before the export of the young plants was, consequently, prohibited.

The beetle deposits its eggs on the host plant just above the ground ; the resulting larvae commence to burrow downwards into the base of the stem, which later, if the larvae are numerous, is transformed into a spongy mass of tissues and finally the plant dies. When full grown the larvae change into pupae at the end of the galleries made by them inside the plant.

The description of the larva, pupa and perfect insect is given.

281 - ***Myelois ceratoniae* and *Ephestia calidella*, Microlepidoptera Injurious to Locust Beans, in Sicily, Italy.** — DE STEFANI, T., in *R. Stazione sperimentale di Agrumicoltura e Frutticoltura, Acireale, Bollettino* 37, pp. 5-6. Acireale, 1919.

From locust bean plants under observation at Palermo the author obtained many adults of *Myelois ceratoniae* Zell. (from the end of April to

mid-August) and of *Ephestia calidella* Guen. (from the end of April to the beginning of September).

In August the locust beans are in the process of drying on the plants. This is the period when the two microlepidoptera (family *Pyralidae*), issuing from the old fruits attack the new ones on the plants which, being gathered in, as is the custom in Sicily, during September-October, will give rise to the first generation in April. On the other hand, the individuals from dried locust beans in store, coming out between April and June, will give rise to two or three generations in the same old locust beans in the stores.

The two insects deposit their eggs only on the beans, near the rib; the caterpillars bore a small hole in the fruits and entering them begin to destroy the pulp; the damage done is severe enough to make the beans so attacked useless. Once their growth is finished the larvae leave the fruits and enclose themselves in cocoons adapted to the places where they have taken refuge.

M. ceratoniae has been got also from dates, dried figs, raisins, and fruits of *Cydonia japonica*. In the larval stage it consumes also the dried-up insects. It is found along all the Mediterranean coast, in Africa, Madagascar, and the Antilles.

E. calidella has also been found in cork trees, as well as in dried figs and raisins. Like the preceding species, its caterpillar consumes the dried-up insects. It has been reported in France, England, Austria, Dalmatia, Germany and Asia Minor.

Organisation of Agricultural Book-keeping in Denmark

by O. H. LARSEN

Professor of Rural Economy at the Royal Veterinary and Agricultural School; Head of the Central Office of Agricultural Book-keeping in Denmark.

I. — LOCAL SOCIETIES FOR AGRICULTURAL BOOK-KEEPING. — The rigin of the first local societies for agricultural book-keeping dates back) the beginning of the twentieth century and was due partly to the)ntrol *societies* that have existed since 1895, and partly to *farm competitions*.

The first society of control was founded at Vejen in 1895, and ;n 918 there were 670 such societies having as their principal object the)stering of the dairy industry. They keep check over milk production nd the content of butter-fat, also on the fodder consumed by each airy cow placed under their control and, by keeping a careful system of ccounts, they are in a position to indicate the most profitable beasts.

Sometimes the book-keeping extends to horses and a check is kept ver their feed and growth; these are the first steps towards a complete ystem of farm book-keeping.

The first society of control that attempted such an extensive system f book-keeping was that of Midt Langelant under the direction of H. C.)UBORG, consulting expert. Since 1907 he has used a system of his wn which, is practically a combination of the single and double systems f entry; the daily entries are not made in the books, but on special forms. /hile the inventory for the year is kept on the double-entry system,

The ledger does not contain many details, nevertheless there are pecial accounts for the more important crops, viz: cereals, root crops, ay, green fodder, as well as accounts for horses, dairy cows, heifers, nd pigs.

When balancing the stock account, this is not debited with the ruling market price of the roughage consumed, but a value is given according to its utilisation by the stock, and the accounts of the various crops are credited with the respective amounts.

Few societies of control have adopted the DUBORG system. Its drawback is the difficulty met with by the controlling officer who has too many farms under his control. He has farm work to attend to besides book-keeping, and it happens with the older societies, that the book-keeping work gets behind. The system therefore could not extend, and it has been found easier to obtain estate subsidies by founding sections of agricultural book-keeping, or local circuits within the already existing agricultural associations.

In the island of Samso there is one of the oldest bookkeeping circuits of this kind; from 1902 till 1908 prize competitions were held there for the best-kept books concerning the various groups of crops. Similar competitions were also held in the following years in other parts of Denmark, but as the interest in complete agricultural accounts grew, so do we find in the majority of places that more branches of the farm were brought under book-keeping control. A system of account-keeping is thus evolved, much alike in principle to that elaborated by DUBORG, although at times differing a little to suit local conditions.

The agricultural society of Kolding adopted the system in 1909, and in 1910 the first independent society of agricultural book-keeping was formed in the island of Samso, this being the development that followed on the institution of farm competitions. In the ensuing years this example was followed elsewhere and since 1910 about 40 agricultural societies have adopted this system of book-keeping, either through the appointment of special book-keeping committees, or by founding independent societies for agricultural book-keeping.

In 1913, the Royal Danish Agricultural Society issued a number of books on the subject, which are very close in their form and substance to DUBORG's; this is therefore the system used by the majority of local societies and circuits of agricultural book-keeping.

The circuits ordinarily do their work thus:— Having first secured a sufficient number of members, the society engages an accountant who will be the consulting expert and whose duties are: —

(1) To help members to establish the system and keep the books.

(2) To guide them in making the daily entries.

(3) To control the entries and make up the monthly cash account, the work book and the fodder account.

(4) To make up the yearly balance sheet.

(5) To make a detailed analysis of all accounts at the close of the year.

The fees which the society charges its members vary from 45 to 100 *ore* per hectare (from about 6*d* to 13 ½ *d*. for 2 ½ acres) according to the area of the farm. Usually the circuits cover a small area, so that one accountant is able to visit each farm of his circuit as often as required

with the exception of the busiest time, when some assistance is needed. There are, however, circuits with more than 1000 members, and in such cases the consulting officer must have one or more assistants.

Since 1915, the societies can apply for a State subsidy amounting to half the salary, office and travelling expenses of the accountant on condition that the government standard of book-keeping be adopted and that the balance sheets be published. The number of State-subsidised circuits for the financial year 1918-19 was about 30 and included 1094 farms with a total of 44.000 hectares ; in 1919 the figures were much higher.

II. — The Office of Agricultural Book-keeping. — It was stated above that it is the rule to publish the results of the accounts of local societies. A general elaboration of the results of of all the societies has not, so far, been prepared, but attempts are being made for each district. The difficulty of elaborating as one whole all the available material for the various parts of the country is partly due to the large number of books, there being more than 1000 in 1918, partly to the lack of homogeneity in the material itself.

In the spring of 1914 the Royal Danish Agricultural Society proposed the foundation of a special office of agricultural book-keeping aiming at procuring all the data for preparing an elementary course on Danish farming. The more complete development of this proposal was entrusted to Mr. O. H. Larsen, Professor of Rural Economy at the Royal Veterinary and Agricultural School.

The principal agricultural societies, after having accepted the proposal in its main lines, constituted in conjunction with the Department of Statistics a special committee, which was to try and establish a special Office of Agricultura lBook-keeping on the lines suggested by Prof, Larsen . The fundamental idea was that this Office was principally to elaborate in a scientific manner, the books of the local societies of agricultural book-keeping, that the Office and the societies should collaborate and that only the best-kept books and those answering the purpose best, should be employed In order to secure homogeneity and reliability, the Office holds every year a course or a meeting where local accountants meet to discuss the systems on which the books are kept and the rules followed for the distribution and allotting of the expenses.

In accordance with the proposal, the first aim of the Office would be to ascertain the :

(1) Amount of capital invested and manner in which it is allotted to the various agricultural enterprises.

(2) Comprehensive budget of gross profits, working expenses, net profits and interest on the capital employed.

(3) Book-keeping of the various branches of the industry showing cost of production, general and working expenses, expenses for horses, implements, etc.

(4) Household expenses.

(5) Income of the farmer and revenue yielded by the enterprise itself.

It may be said that the Office started to work on this principle in the spring of 1916 ; during the first 2 years the work was of a preparatory nature and only in the spring of 1918 was the organisation of the scheme effected and a satisfactory collaboration secured from the local societies. For the year 1919-20 the collaboration comprises a total of 29 societies and the number of books that will have to be elaborated will probably be 350. For the 2 previous years. 1916-17 and 1917-18, collaboration was extended by 6 and 17 more societies respectively with 75 and 235 books. The first report concerning the year 1916-17 was published in the autumn of 1918, and the second, referring to 1917-18, in the autumn of 1919.

The Office is under the supervision of 7 members representing the societies and the institutions which took part in its foundation. At the head of the Office there is Professor Larsen, the daily work is supervised by the consulting accountant IVAR DOKK, who is helped by a permanent assistant and by one or more temporary officers as circumstances may require.

During the first 2 trial years the working expenses of the Office were borne by the Royal Danish Agricultural Society ; for the financial year 1918-19 it received 12 000 *kronen* (1) as State subsidy and 1800 *kronen* as the contribution of agricultural societies which are represented on the Committee. The State subsidy was raised to 15 000 *kronen* for the financial year 1919-20, while the contribution of the societies will depend on the work and whole expenditure.

The local societies of agricultural book-keeping receive besides a free supply of account books, a bonus of from 5 to 6 *kronen* for every book containing data that may be useful to the Office. On the contrary the concerns that correspond directly with it and get assistance from it for their book-keeping, pay a contribution in proportion to their size and to the extent of their book-keeping. It varies from 35 *ore* to 1 *krone* per hectare.

(1) 10 *ore* = 1 *krone*; 1 *krone* = 1s $1^1/_2d$.

AGRICULTURAL INTELLIGENCE

GENERAL INFORMATION

282 – **The Cultivation of Duckweed for the Control of Malaria.** — REGNAULT, F., in *Bulletin de la Société de Pathologie exotique*, Vol,. XII No. 10, pp. 735-736. Paris, Déc. 10 1919. RURAL HYGIENE

When duckweed (*Lemna* spp.), completely covers the surface of marshes, it causes the larvae of mosquitoes to disappear, because these, being unable to come to the surface and breathe, die of asphyxiation. Professor LAVERAN states in his *Traité du paludisme*, (second edition, p. 654), that CENTANNI and ORTA suggested the use of duckweed for the destruction of these larvae, "it is possible that this means might be useful in some particular cases".

In 1917, the author was at Ajaccio, Corsica, and noticed in the neighbourood of that town that some few boggy marshes were covered with duckweed and, consequently, free from mosquito larvae, while a great number of other marshes contained clear water had no duckweed and were alive with larvae among which could be recognised those of Anopheles. The author put duckweed in some of these marshes, but they died; on recollecting that these will grow in water charged with organic matter, he threw in some horse and cow dung after which he sowed duckweed lentils. These multiplied and grew thicker and the mosquito larvae disappeared. When the organic matter was used up the duckweed died. The author was able to repeat the experiments several times with the same result in every case.

It should be easy to grow duckweed In the struggle against malaria it would be advantageous to employ it on extensive marshes where paraffin would be costly.

The disappearance of duckweed is one of the causes of the appearance of malaria in the countries ravaged by the war. Men and cattle have died there, the shepherd takes the place of the agriculturist, the land is grazed extensively where formerly it was intensively farmed. The water, when the organic matter is used up, becomes clear again and suitable as

breeding places for anopheles. Furthermore, the obstruction of drains and irrigation canals, the destruction of trees and cultivated fields favour the stagnation of water.

283 – **Precautions to be taken in Case of Bite by the "Lucacha" (*Latrodectus mactans*), a Small Poisonous Spider of Peru and Various Other Countries.** — See No. 334 of this *Review*.

284 – **The Effect of Milling on the Digestibility of Graham Flour.** — LANGWORTHY, C. F. and DEUEL, H. J. (Office of Home Economics, U. S. Department of Agriculture) in *Proceedings of the National Academy of Sciences*, Vol. V, No. 11, pp. 414-517. Washington, Nov., 1919.

In the United States, the bulk of the wheat used for flour is made into flour which contains 72 % of the wheat kernel, called " patent flour "; part is made into flour containing 85 %, called " entire flour " or " whole-wheat flour "; part is also made into flour which contains 100 % of the wheat kernel, known as " Graham flour ". The flour containing 72 % has a much higher digesfibility then that of the flour containing from 85 % to 100 %, as the coefficients of digestibility in Table I show :—

TABLE I. — *Coefficients of digestibility of flours of various percentages.*

	Tests by other authors.		Tests by the authors.	
	Number of tests.	Coefficients of digestibility.	Number of tests.	Coefficients of digestibility.
Flour containing 72 % : —	31		43	
Protein		88.1		89.5
Carbohydrate		95.7		99.9
Flour containing 85 % : —	23		16	
Protein		81.9		87.1
Carbohydrate		94.0		98.3
Flour containing : —	24		33	
Protein		76.9		84.2
Carbohydrate		90.1		94.4

The method of milling affects the size of the particles and the extent to which the walls of the aleurone cells are broken or weakened (while kneading, the walls of these cells are broken at the weak places). The authors investigated the effect of the various methods of milling on the digestibility of Graham flour. A Minnesota spring wheat was milled in 5 different ways; the flour was made into bread (with small quantities of lard, molasses, salt, ginger and baking powder), and the resulting bread was eaten by men with fruit (oranges), butter, sugar, coffee or tea, in food tests. For determining the results the usual analytical methods were employed. The results of the digestion tests are set forth in Table II, in which the flours obtained by the various methods of milling are classed

in increasing degrees of fineness. They show that the digestibility of the protein increases with the degree of fineness, as might be expected, for it has been shown (*U. S. Dept. Agric. Bull.* 751, 1919) that the protein of bran is digested to the extent of 44 % in the case of fine bran, and 28 % in the case of coarse bran; on the other hand, the digestibility of the carbohydrates varied slightly. In Table II, the estimated digestibility of the protein and the carbohydrate represent the digestibility of these constituents in the flour alone, after allowance has been made for the undigested residues of the other foods in the ration.

TABLE II. — *Fineness and average digestibility of Graham flour milled by different methods.*

Methods of millings	Percentage of flour passing through 100 sieve.	Digestibility of the flour.					
		Digestibility of the entire ration.				Estimated digestibility of protein.	Estimated digestibility of carbohydrate.
		Protein.	Fat.	Carbohydrate.	Ash.		
Laboratory roller mill	8.2 %	72.1 %	94.4 %	96.0 %	70.1 %	70.7 %	95.3 %
Commercial roller mill	22.8	72.1	95.6	95.4	67.6	70.4	93.8
Steel-burr mill	32.4	79.2	95.0	96.1	73.8	78.5	95.3
Attrition mill	36.6	75.5	92.9	96.1	69.7	74.5	95.4
Stone-burr mill	39.2	79.2	96.5	96.6	78.4	78.2	96.8

285 – **Comparison of the Feeding Values of Different Bread-Making Flours.** — *Feuille d'Informations du Ministère de l'Agriculture*, Year. XXV, No. 4, p. 6. Paris, Jan. 27, 1920.

At the meeting of the *Académie de médecine* of Paris held on December 1919, the results of the researches made by Messrs. ACHARD and GAILLARD were communicated, bearing on the effect of feeding animals on different bread making cereals on their development, viz., wheat, maize, rye, barley, rice when added to the normal ration consisting of cabbages and carrots. The addition of bread flour has given various results as regard to the increase of weight and the health of the subjects.

These results could not be directly and principally attributed to the nature of the flour employed. The main conclusion that is drawn from these studies is that there seems to be no difference of any importance, as far as general nutrition is concerned, between the various types of flour. These results could not be extended to the case of man without reservation, all the more so, because in the feeding of human beings these flours are consumed cooked as bread, not uncooked as in the experiments referred to above.

286 – **Direct Replacement of Glycerol in Fats by Higher Polyhydric Alcohols.** — I. LAPWORTH, A. and PEARSON, L. in *The Biochemical Journal*, Vol. XIII, No. 3, pp. 296-300. — II. HALLIBURTON, W. D., DRUMMOND J. C., and CANNAN, R. K., *Ibid.* pp. 301-305. Cambridge, Nov., 1919.

I. INTERACTION OF OLEIN AND STEARIN WITH MANNITOL. — In the extraction of glycerin from fats by ordinary methods the by-products have a very limited application as food-stuffs. To obtain a wider application, it has been suggested, among other processes, that the fatty acids should be converted into their esters (ethyl and others). The author proposed to investigate the results of esterifying with polyhydric alcohols simlar in type to glycerol ; on the other hand, Professor ROBINSON is at present investigating the esterifying with sugars and their simple derivatives. As alcohol, the authors selected for their experiments mannitol ; as fats, olive oil and stearin. They note the following facts : — By distillation of olein or stearin with mannitol, under reduced pressure, in presence of a little sodium ethoxide (which acts as catalyst), nearly all the glycerol present in the original fatty compound is expelled. The maximum yield of glycerol is obtained when the proportion of fat to mannitol corresponds to 2 molecules of the former to 3 of the latter. In both cases the other principal products of the reaction are water, a little alcohol and a substance which, in many respects, is similar to the original fat. When fat and mannitol are used in the above mentioned proportions, or when there is an excess of mannitol, the composition of the product corresponds with that of a mixture of di-oleates (or di-stearates) of mannitan and isomannide.

II. — THE VALUE, AS A FOOD, OF SYNTHETIC MANNITOL OLIVE OIL. — This product, of a light greenish brown colour, has an odour reminiscent of olive oil and has, compared with good commercial olive oil the following constants :—

Constants	Synthetic mannitol olive oil	Olive oil (natural)
Free fatty acids, calculated as oleic acid	4.0 %	2.7 %
Saponification value	159	193
Iodine value.	82.4	84.7

The prolonged, feeding tests, were made with rats placed on mixed diet. Utilisation of 97.8 % for the butter + olive oil mixture ; 96.6 % for olive oil ; 95.8 % for synthetic mannitol olive oil was noted. The latter is therefore practically utilised in the same proportion as natural olive oil. Furthermore, its use is by no means injurious to health and in no way hinders growth.

287 – **Bacteriology of Egg Powders.** — *Feuille d'Informations du Ministère de l'Agriculture*, Vol. XXV. No. 4, p. 6. Paris, Jan. 27, 1920.

At the meeting held on January 6, 1920 by the Academy of Medicine Paris, the results of the investigations by Dr. A. SATORY and D., L. FLAMENT on the microbic flora of dried egg powders as sold in commerce,

were published This flora is important. It is usually aerobic, and includes micrococci which do not liquefy, and others which liquify in gelatines as well as members of the *Bacillus coli group*, etc. These powders are contaminated.

The various brands on the market are not sterilised. In the preparation of creams and many dishes, these powders are not raised to a sufficient temperature for sterilisation.

CROPS AND CULTIVATION

288 – **Weather Forecasing at the Station of Agricultural Meteorology, Montpellier.** — See No. 369 of this *Review*. AGRICULTURAL METEOROLOGY

289 – **Agricultural Meteorological Investigations in Scotland.** — BEDFORD, FRANKLIN, E. in the *Journal of the Scottish Meteorological Society*, Vol. XVIII, 3rd Series, No. 26, pp. 76-83. Edinburgh, 1919.

Having noted the predominant action of the weather in connection with the annual oscillations of the yield, the author gives the results of investigations and experiments with a view to discovering the effect of adverse weather by means of appropriate cultural methods tending specially to modify the hygroscopic and thermal nature of the soil.

TEMPERATURE. — In Scotland, towards mid-February, the soil temperature, is reduced almost to 0°. to a considerable depth, The increasing rise in temperature, helped by the warm spring showers and by sunshine, but hindered by nocturnal radiation and by frequent returns of cold, is rather slow. It is only towards the end of March and the beginning of April, that a temperature suited to growth and vegetation and to bacterial activity in the soil is reached (5.6° C).

1919	Temperature at surface soil.		Temperature at 1yd depth.	
Season	Maximum.	Minimum.	Maximum.	Minimum.
March 10-19	1.67°	—1.39°	1.39°	0.61°
March 20-29	2.50°	—1.11°	1.67°	1.00°
March 30-April 8	10.61°	4.72°	6.56°	5.00°
April 9-18	14.44°	3.89°	7.78°	5.50°
April 19-28	16.67°	3.06°	11 11°	5.50°
April 29-May 8	12.50°	7.00°	10.00°	6.00°
May 9-18.	20.89°	8.33°	13.89°	8.89°

Any cultural method tending to increase the thermal reserves above 5.46° would have a favourable influence on plant development and renewed growth.

By simply using a covering stretched over a plot cultivated with potatoes, the author obtained, at certain hours in the day, temperatures superior to the minimum temperature necessary for growth, while under

the open sky, as a result of the suns' rays, the temperature remained always below 5.56° C. In the case of a protected seed-bed, the seedling stage and the succeeding phases of development are considerably advanced, and the crop of tubers can be obtained three weeks or a month earlier than usual.

Besides methods employed to hinder the effect of the sun's rays, it is possible to employ others tending to increase the thermal capacity of the soil, notably: *rolling* (according to KING the difference between the same types of soil whether rolled or not, is at a depth of 75 cm, about 1.7° C), *manuring* (increase of 1.1° C.) and good *drainage* (increase capable of reaching 2.4° C).

Concerning soil temperature, the April rains are very advantageous to agriculture ; the damp soil is a better conductor of heat, and the heat penetrates the soil more rapidly, raising the temperature in the layer where the roots grow, and where the seeds await favourable thermal conditions to enable them to germinate.

Surface tillage, done with a view to stopping the water from flowing off, and causing instead direct absorption, has also an advantageous influence on cultivated plants.

MOISTURE. — The dryness at the end of the spring and in the summer, accompanied sometimes by dry southwesterly winds, may frequently cause considerable damage. From that time, there is an obvious expediency in encouraging moisture absorption in the first half of the spring in order to be able to cope successfully with the dry period which may follow.

In 1916, a clay-loam meadow was cleared in order to plant potatoes as soon as possible after ploughing and manuring. The rainfall was normal, but there were strong and continuous southwesterly winds which dried up the ground very quickly. The yield was only 12 500 kg. per hectare, with an average of 16 300 kg. for the entire district.

The production of a metric ton of potatoes necessitates about 87.5 mm. of rain, but in the example selected, the plants used only 437.5 mm. of rain, whilst the rainfall in the corresponding period, was 450 mm. more than all the moisture previously stored in the ground.

The following year plans were made to remedy these disadvantages.

Directly after the harvest in 1916, the ground was dug to 45 cm. depth, then left as fallow land during the whole winter, in a fit condition to absorb the rain easily. As a result, the following spring the moisture was 10 % superior in quantity on this plot compared with neighbouring territory. Manure was applied and spring operations on the land were carried out so as to maintain, soon after planting out, a well tilled layer of surface soil, in such a way that the stored-up water would not be drawn to the surface by capillarity, followed by loss by evaporation.

In 1917, as in the preceding year, there were unfortunately strong southwesterly winds, and, during the growing period, the total precipitation was only 375 mm. lower than that of 1916. Nevertheless, the yield was 27 600 kg. per hectare (average of 22 600 for the district) coresponding to 962 mm. precipitation. Thanks to the cultural work carried out, the rains and

reserve moisture in the soil were used to their maximum capacity and the effect can be considered due to a depth of water of 587 mm., the difference between the rainfall during the vegetation period, and the absolute quantity corresponding to the total crop.

290 – **Investigations on the Cooling of the Soil During the Night, with Reference to Spring Frosts, in Scotland.** — FRANKLIN, T. BEDFORD in *Proceedings of the Royal Society of Edinburgh*, Vol. XXXIX, Part. II, pp. 120-136, figs. 3, Edinburgh, Oct. 1919.

In studying the cooling of the soil during the night, the laws which govern this phenomenon and the consequences that it may have for cultivation, the basis almost always used is the temperature taken immediately above the grass which generally covers the ground, without taking into consideration the differences, sometimes very considerable, between these temperatures and those at the surface of the soil itself.

The author gives the results of a series of investigations which he carried out in Scotland with the object of thoroughly studying the phenomenon of the cooling of absolutely bare soil or soil more or less protected by vegetable growth. The cooling of the soil during fine nights is due to radiation, and the effects of radiation are at first counterbalanced by the conductivity of the earth which conducts heat from the deeper layers to the surface and then, when the surface commences to freeze, the latent heat of freezing water is liberated and must be eliminated by radiation before further cooling is possible. It is only when these two factors have been counteracted that radiation can directly lower the temperature of the soil. The temperature at the surface of the soil depends therefore on: — (1) The relative humidity of the air; (2) the dryness of the surface layers; (3) the temperature of the layers immediately below.

The result of the observations made, confirms the correctness of the considerations set forth above. Particularly the rate of radiation of the soil (on calm clear nights when 5th magnitude stars are visible to the naked eye) is a function of the relative humidity. The other causes (condensation, evaporation, etc.) have very little effect on the temperature of the soil.

The temperature at the surface tends to fall rapidly below the temperature at a depth of 4 inches up to the point where conduction from this depth balances radiation. When this balance has been effected, the temperature at the surface should fall at the same rate and in the same manner as at a depth of 4 inches, and if the temperature of the subsoil is high there is little probability of frost.

The difference in temperature between the surface and the layer of 4 inches which establishes the balance between conduction and radiation is probably 10° F. during the winter (when the ground is always moist and of uniform maximum conductivity), but may be as much as 20° F. after a dry period in spring or at the beginning of summer.

According to these data it appears possible to predict frosts by examining observations of the humidity and temperature of the soil taken at noon. Actually four separate values have to be predicted:—

(1) The average relative humidity during the night;

(2) The temperature at a given depth (for example 4 inches) at the time when the temperature at the surface of the soil reaches its minimum.

(3) The conductivity of the layer between the given depth and the surface.

(4) The difference between the surface soil minimum and the minimum in the air immediately above.

The author believes that, taking these phenomena into account and by using sets of electrical resistance thermometers, it will be possible in the near future, to predict with great accuracy the minimum night temperatures.

When the soil is covered with a poor heat-conducting material — radiation is considerably reduced. To determine the specific effect of various covering materials the author has made a series of observations of minimum temperatures under 6 different conditions: —

(1) Bare compact soil (control).
(2) Soil covered with a layer of ½ inch of loose raked soil.
(3) Soil covered with a layer of ½ inch of ashes.
(4) Soil covered with a layer of ½ inch of manure.
(5) Soil covered with a layer of ½ inch of dead leaves.
(6) Soil covered naturally with grass and moss.

The maximum thermal efficiency of these substances was on the average: — 3° F. for, loose raked soil; 6° F. for ashes; 6.5 F. for manure; 7° F. for dead leaves; 10° F. for natural grass and moss.

On the slopes of ditches, near hedges, in the woods, the roots of many herbaceous plants, protected by a surface layer of dry leaves, are very rarely injured by frost. If in such cases, a warm rain, say in December, raises the temperature of the soil to the extent required for growth, these plants may grow and even flower in the middle of a rigorous winter. For example the author has noticed a primrose which, owing to a period of mild weather in December, 1918, had grown through the mossy turf which protected it and managed to flower on February 10, 1919. At that time the leaves and flowers were exposed to an air temperature of 15° F., while in the soil at the level of its roots the temperature was 33° F. or 18° F. higher.

Therefore, so far as the lateness or earliness of spring wild flowers are concerned, it appears that predominance should be attributed to the temperature of the soil, while the temperature of the air has, from the same point of view, much less influence.

291 — **Considerations on the Rainfall in Indo-China and their Consequences from the Standpoint of Cinchona Cultivation in that Colony.** — See No. 331 of this *Review*.

292 — **Unseen Condensation of Water Vapour due to Trees.** — Descombes, P., *Comptes rendus hebdomadaires des Séances de l'Académie des Sciences*, Vol. 169, No. 23, pp. 1106-1108. Paris, Dec., 1919.

When the " Association Centrale pour l'Aménagement des Montagnes " founded by the author at Bordeaux in 1904, took steps to carry on

re-forestation with the object of increasing the resources of " white coal "' the author drew attention to the hydrologic action of forests, and stated that trees cause abundant precipitations without any fall of rain. An enquiry into this statement elicited much interesting information. In California, where there is no rainfall from the beginning of June to the end of September, trees are all the time very damp, the surrounding prairies are green instead of being bare ground (Sir GARDNER REED). Lake Léman is fed by the canton of Vaud and by the Haute Savoie with a proportion of forests of 25 and 28 per cent., respectively, and delivers a quantity of water superior to that due to rain and snow (FOREL). The same occurs on the Haute-Marne-where 31 % of the country is forest. (MOISSONNET).

On Table Mountain, Cape of Good Hope, 1163 metres high Dr MARLOTH placed two rain gauges ; on the top of one he put an armful of brushwood and twigs and, at the end of the experiment which lasted 56 days, he collected 2270 mm. of water in this and only 126 mm. in the control gauge.

Dr. GEORGES V. PEREZ states that abundant unseen condensation occurs in the Canary Islands where the " tils " (*Oreodaphne foetens*) supply Mont-Verde with moisture and where the " garoe ", the holy tree of Iron Island collects enough water to supply the population of the island, which has no springs.

The above-named *Association Centrale* conducted certain experiments at various stations with a cylinder 30 m. high, lined with thick woollen cloth, and with an external surface equal to some 4 times horizontal projection. The following result is worthy of note: — The quantity of dew collected in 1919 by COURTY at the Bordeaux-Floirac observatory was about 4 times larger than the mean recorded by HOUDAILLE at Montpellier with the ordinary dewmeter.

The author calculated on the strength of numerous data the total amount of atmospheric precipitations plus that which is due to condensation on ground covered with vegetation, and situated in a mountainous zone of the Pyrenees where the precipitations average 40 inches per year and where 40 % of the soil is covered with vegetation. Taking this as the annual mean we have for the various cases : 1.16 m., " on ground completely treeless; 1.51 m.," on ground where 5 % of the area is timbered and 5 % is scrub ; 2.97 m." on country with 30 % of forest and 1.62 m.," on ground covered with scrub to the extent of 50 %.

Reforestation requires time and its hydrologic effects are not immediate ; the experience gained by the *Association Centrale* on the Pyrenees and Alps go to show that it suffices to keep away sheep and goats for 5 years from those mountains at the cost of 5 francs per hectare to enhance the growth of many trees and scrub without entailing any hardship on the inhabitants and their flocks. Reforestation plays therefore an impor-tant part in encouraging the gradual increase in " white coal " supplies.

293 – **Hard Pan in the Apulian Soils and its Origin. Researches on Soil Chemistry in the Bari District** (1). — De Dominicis, A., from the *Annali della R. Scuola Superiore di Agricoltura di Portici*, Vol. XV, pp. 39, 1 map. Portici, 1919.

The work was carried out in the laboratory of Agricultural Chemistry of the Royal School of Agriculture at Portici, near Naples. It includes an investigation bearing on the physico-chemical composition of the soil; on the chemical nature of its ingredients; on the chemical composition of the well waters and of the materials forming various layers of the soil selected for the research and of those of the subsoil; on the amount of water absorbed by the constituents of the various layers of the soil in an environment saturated with moisture; on the percentage of water absorbed by the same after 24 hours' immersion (from 10.28 to 20.60 %) on the loss of water through evaporation after immersion (from 9.90 to 23.67 after 36 hours); on the speed and percentage of water rising through capillary action; on the physico-chemical composition of the hard pan (average of 2 samples: sandy matter 9.16, colloidal matter 2.87, calcium carbonate 87.17, organic and volatile matters 20, soluble sub stances,57).

The results of the investigation enable the author to conclude: — When it is undertaken to change the local agriculture or to intensify farming in that part of the country the most essential factor is that connected with the removal of hard pan, " crosta pugliese ". This very hard layer of calcareous crust runs uninterruptedly between surface soil and subsoil, it prevents the roots from penetrating and also interferes with that free play of the water rising or descending, which is so very providential to vegetation. This telluric phenomenon reduces to a large extent the natural fertility of that soil which is washed off the higher ground and the hillsides denuded of timber and accumulates on the plains. These conditions are more uncommon in the country round Bari, where the pan firmly adheres to the rocky tufa. In other parts of Apulia, on the contrary, as in the Tavoliere and about Barletta the subsoil is friable.

The rocky mass constituting the subsoil in the Bari territory possesses a high degree of permeability, owing to its nature of calcareous tufa of pliocene origin. Its hydric capacity, however, is limited, but is sufficient for trees. Nevertheless, rain waters do not penetrate as far down as the water circulating in the soil, which otherwise would have to rise through capillary action. This is principally due to the rainwater, which is not retained through the absorbing power of the soil and cannot penetrate the crust; consequently it runs off along the layer formed by the crust itself and gets lost through the cracks and fissures.In doing so it carries off earthy material thus causing a decrease of the depth of the arable soil. The capillary system i also very active in these rocks; this is why the removal of the crust is considered dangerous by the local agriculturists who, on the contrary, look upon it as the agent preventing the loss of the water reserves below it.

The pan rests on the top of rocky layers and is always next to the arable soil; its origin, therefore, is not connected with the farthest limit

(1) See *R.* May 1919, no. 560; *R.* July-Sept. 1919, No. 822; No. 304 of this *Review*. (*Ed.*)

of penetration of the descending water, nor with the re-deposition through evaporation of the calcium carbonate dissolved in the rising water. Where it is due to the latter circumstance its position not only should be close to the surface, but outcropping altogether ; its position on the contrary is indicated by the layer where the capillary water meets the solution running through the soil. In fact, the ingredients of both waters being found in the pan, its formation is consequently due to the reactions taking place when the two waters mix. The constituents of the crust are the colloidal substances found as hydrosols in the circulating water and the calcium carbonate which is dissolved in the capillary water : the nature of the reaction is that of the coagulations which take place through the action of the electrolytes upon the hydrosols. The proof is that no crust is to be found under the red earth (*terra rossa*) because being of lateritic nature, it is poor in hydrosols. The content and proportion of limestone in the crust are essentially due to the absorbtive powers of the coagulating agent for calcium carbonate. This is taken in the mesh of the coagulating agent, it gradually replaces the water, and reduces the reversibility and swelling of the hydrogels. The whole mass thus takes shape, becomes compact, hard and impermeable. The crust is not altogether impermeable, but the capillarity is nil ; this is due to the nature and properties of a thin coating on the surface of the crust. The formation of this limestone pan is of historic origin because its formation implies absolute immobility as regards environment : such conditions could only prevail where no agriculture existed. These coincide with the 2000 years during which, dating back to the Roman republic, the country was only pastoral.

The problem concerning the possibility and desirability of removing the pan also includes methods the application of which, would lead to a change of climate and soil ; these are : irrigation, nature of the subsoil, dry farming, use of explosives, arboriculture, reforestation, etc.

294 – **On Soil Absorption.** — RAMANN, E. and SPENGEL, A. (Mitteilung der bodenkundliche Abteilung der Königl. Bayerischen Forstlichen Versuchsanstalt), in *Die landwirtschaftlichen Versuchsstationen*, Vol. XCII, Part 3-4, pp. 127-146, 6 plates. Berlin, 1918.

In order to study soil absorption, the authors carried out some experiments concerning the exchange of bases through the action of dibasic solutions, taking permutit (1) as the starting point.

When treating this silicate with neutral double solutions of potassium, ammonium, calcium, and sodium salts, the displacement of bases which occurs has all the character of a chemical action and not that of physical absorption. The exchange of bases takes place according to the laws of chemical equivalence and, in the case of potassium and ammonium, according to the law of mass action ; in fact, for the two latter elements the curves represent-

(1) Artificial sodium zeolite, that is, hydrated silico aluminate of sodium found by GANS : this compound is notable for its absorbtive power for potassium, calcium, magnesium, manganese, iron, due to the exchange taking place between these bases and the sodium of the silicate itself, the sodium passing into solution. (*Ed.*)

ing the ratio between the ions in solution and the ratio between the bases incorporated in the silicate, practically coincide. On the contrary, with the solutions contaning sodium and calcium, the exchange of bases follows as a rule the ratio of the ions of the solution, but the predominance of this or that salt causes divergences depending on an unknown factor.

Potassium and ammonium substitute one another and completely replace the sodium and calcium of the silicate, but the substitution of potassium and ammonium in the silicate by sodium and calcium is incomplete. The ratios between the bases in solution and those in the silicate are various and thes bases, which are present in the solution in very small proportion, may be found combined in the silicate in large proportion. Taking a wider range, it may be said that absolute concentrations of salts in solution have no marked influence on the composition of the silicate and this applies also to solutions of bivalent calcium with monovalent elements. *Mutatis mutandis* the same final equilibrium observed in the case of permutit, very much akin to the soil silicates, exists in the soil itself ; in fact if we take soils in equal conditions, the ratio between the bases is constant, although in the soil solution the concentration may vary.

PERMANENT IMPROVEMENT DRAINAGE AND IRRIGATION

295 – **Electricity and Soil Improvement in Italy.** — I. Elettrocultura, in L'*Impresa Elettrica*, Year XXI, No. 11-12, pp. 451-452. Rome, 1919. — II. Royal Decree-Law No. 1995 of October 2, 1919 containing provisions in favour of the production and utilisation of electrical energy. *Ibid.*, pp. 475-477. — III. Committee for Electroculture. *Ibid.*, pp. 310-511.

I. — There is much to be done in Italy to raise all the territory of the country up to the same level of production. Northern Italy has become what it is, because the waters have been regulated and harnessed, because the soil has been generously manured, and also through the large use of agricultural implements. The agricultural and industrial problems of Southern Italy, on the contrary, will be solved through artificial lakes, forestation and through the improvement of the land. It was once considered impossible to create there any great water reservoirs and that in that part of Italy it would never be possible to produce, carry and distribute electrical energy on a large scale. Electrical enterprises have already proved that by closely studying a problem the impossible may become possible, and, within a few years, if there be no untoward events in the Italian electrical industry, Southern Italy will have hundreds of thousands of h. p. available, and it will be possible largely to provide for irrigation. There are plans for the improvement of unhealthy country which have been waiting for decades and which can be read in the fine volumes of parliamentary proceedings. As they were then studied, they could never be carried out now, as such studies were founded on ideas now obsolete. For the solution of such problems new ideas, new people and modern means are required. Electricity is bound to succeed there, because of the connection existing between the regulation of the water-courses and the creation of reservoirs and irrigation, also because of the use of electric-pumps in all irrigations and works for the drainage of unhealthy country.

II. — The Italian Government signified their intention to make elec-

trical energy available in agricultural districts for the increase of production, and have passed a decree which contains the following provisions relating to Agriculture: —

Art. 13. — Subsidies are granted for 15 years equal to those granted to all existing hydraulic syndicates for irrigation and land improvement which take currents over 2000 volts in their own cables from generating stations for use in agriculture or land improvement. A contribution amounting to 40 % of the cost for the erection of complete sub-stations is also paid by the Government. (Decree of the Lieutenant Governor of February 9, 1919, No. 185).

Art. 14. — A bonus of 0.3 lira per Kilowatt is given to the same beneneficiaries referred to in Art. 13 who utilise electrical energy for the work of cultivation of arable land. This bonus will be granted annually for a period not exceeding 10 years and not after 1940.

Art. 15. — Those who undertake irrigation with water raised by electric power will be eligible for bonuses assigned by this decree or can decide to share in the awards fixed by preceding orders. (Law of Feb. 28, 1886, No. 3734; Law of Jan 10. 1915, No. 107, Lieut. Gov. Decree of May 15, 1919, No. 820).

Art. 18. — Hydraulic or improvement consortia, and consortia of farmers alone or associated, can take up concessions for the construction of central electric stations, keeping the relative accounts separate.

Art. 20. — The " Cassa depositi e prestiti " will set apart a fund for the encouragement of mechanical and electrical applications to agriculture.

III. — The Society among all proprietors of electrical enterprises in the kingdom have appointed a board for the study of electro-cultivation. The board have already initiated their work on the following programme: — *a*) Irrigation improvements by means of electric pumps; *b*) agricultural improvements as a consequence of the former, carried out with all modern machinery worked by electricity; *c*) irrigation, whether by pumping water from the subsoil, or by lifting water to be canalised and distributed for irrigation purposes; all this in connection with the problem for the systematisation of mountain basins, lakes and artificial reservoirs; *d*) motor ploughing; *e*) various applications of electric motors to different farm operations.

Of all these problems it is certain that that which concerns the regulation of water is the most important, because with it is connected the freeing of marshy country from malaria. This question should be considered in relation to the small areas, for with electric pumps, it will be always and anywhere possible at a very small cost to give the waters an outlet, whatever might be the elevation of drains, sewers, etc. compared to that of the largest water-courses, lakes or of the sea. The problem of irrigation is all important, because it would bring about increased production of grain and fodder now so scarce.

Societies for electrical enterprises in Italy have ever taken fresh initiative and in the new work before them, they may be able to do a great deal, specially if associated with the farmers.

The work of the board should be:— to collect all data regarding the various Italian regions; to give directions for the execution of works, and for the supply of electrical energy; to regulate the supply according to the energy available, to study the best machines, to undertake practical experiments even with the assistance of foreign specialists and publish the results; to make suggestions to the Government on matters of legislation; to organise exhibitions of agricultural machinery worked by electricity; to help and in every way smooth the path and encourage the initiative of the individual and above all else to carry on active propaganda.

296 – **Means whereby Soil Erosion May be Prevented in Old Plantations.** — See No. 328 of this *Review*.

MANURES AND MANURING

297 – **New Guano Deposits in the Island of Sardinia.** — De Dominicis, A., from the *Annali della R. Scuola Superiore di Agricoltura in Portici*, Vol. XV, pp. 12 Portici, 1919.

Dr. Altara discovered 6 caves containing important deposits of bat guano in the districts of Dorgoli, Oliena and Orosei. The author states that the chemical nature of this guano participates of the two types, the nitrogenous, and the phosphatic guano, and that though it contains much foreign matter it is a rich manure that can be readily utilised. The following are analytical results (17 samples) showing maximum and minimum percentages:— Water and volatile substances at 100° C: 6.20 to 25.38; organic matter 5.55 to 46.27; mineral substances 30.23 to 75.87; total nitrogen 44 to 7.14; nitric nitrogen 12 to 3.91; uric nitrogen 17 to 4.45. The average percentages are respectively: 15.09, 26.12, 58.77, 2.86, 1.27, and 1.56 %.

298 – **Production of Farmyard Manure in Union of South Africa.** — Hall, T. D. (Lecturer in Chemistry, Potchefstroom School of Agriculture), in *The Agricultural Journal of South Africa*, pp. 9-21, Johannesburg, June. 1919.

The available quantities of farmyard manure from the different classes of animals of South Africa are estimated by the author as indicated in the following Table:—

Kind of animal	Approximate number	Manure produced per annum	Value of manure
Cattle	6 000 000	46 800 000	£ 29 250 000
Horses	720 000	4 320 000	4 334 833
Mules	95 000	2 392 000	—
Asses	340 000	—	—
Sheep	35 000 000	26 250 000	28 328 125
Goats	12 000 000	9 000 000	9 917 500
Pigs	1 090 000	1 853 000	1 474 679
Poultry	10 600 000	465 000	486 312
Ostriches	747 000	—	—
Totals	**66 592 000**	**91 080 000**	**£ 73 588 449**

Sheep furnish the richest manure in fertilising constituents, while cattle produce the largest quantity and the greatest total value.

The author asserts that farmyard manure is the best complete manure for increasing the fertility of South African soils. He recommends the addition of bone meal which greatly increases its fertilising value and gives a handsome return.

299 **Beneficial Action of Farmyard Manure in Preventing the Injurious Effects of Alkaline Salts in the Soil.**— LIPMAN, C. B. and GERICKE, W. F. (California Agricultural Experiment Station), in *Soil Science*, Vol. VII, No. 2, pp. 105-120, Bibliography of 2 works. Baltimore, M. D., 1919.

Experiments in pots made in a greenhouse with barley in clay soil with the object of determining the action of farmyard manure on soil to which had been added in different series: — 0.3 % sodium chloride, 0.3 % sodium carbonate, 0.6 % sodium sulphate before sowing the first crop and additional quantities at the same rate before sowing the second crop ; four successive crops were grown ; the manure was applied at the rate of 20 to 160 tons per acre.

The results, estimated according to the weight of the crops, show the protective action exercised by the manure against the alkaline salts present ; the action varied with the quantity of manure applied and with the chemical nature of the injurious salt ; it also depended on the sum *internal surface of the soil* + *internal surface of the manure applied.*

More positive results were obtained against sodium chloride and sodium sulphate ; in general, they have a practical application of considerable value.

300 – **The Influence of Fertilisers on the Betanical Composition of Pastures. in the United States.** — SKINNER, J. J. (Soil Fertility Investigations, U. S. Department of Agriculture) and NOLL, C. F. (Agronomy Department, Pennsylvania Agricultural Experiment Station), in *Soil Science*, Vol. VII, No. 2, pp. 161-175, 4 fig. 2 pl., Bibliography of 5 works. Baltimore, 1919.

A pasture on loam soil received for 7 consecutive years superphosphate, sodium nitrate, and potassium chloride in a double triangle arrangement of plots with 66 mixtures of fertilisers plus 6 controls ; the total amount of fertilisers applied annually was 50 pounds per acre ; the plots were 10 feet square and were separated by 2-foot paths ; the grass was cut once a year so as to allow natural seeding. The principal forage plants were : — *Poa compressa*, predominant at the commencement, *P. pratensis*, *Phleum pratense*, with smaller proportions of white clover and red clover. At the end of the experiment *Poa pratensis* had become predominant especially in the plots which had received most nitrogen, while *Phleum pratense* was favoured by potash ; clover, however, did better in the plots where there was least nitrogen applied.

The soil of the plots receiving well balanced mixture or mixtures containing principally sodium nitrate remained neutral, whilst when no nitrogen, or only a small amount, was applied it became acid ; this, however,

did not hinder the growth of clover, although in such cases it is favoured by liming.

To sum up, the predominance of a given species of forage plant in a pasture is very probably due to the survival of those species which the fertiliser applied suits best, such fertiliser being possibly at the same time prejudicial to other species.

301 – **Researches on the Velocity of Solubility of Phosphoric Anhydride in Basic Slag and Other Phosphates.** — MASCHHAUPT, J. G. (Rijkslandbouwproefstation te Groningen), in *Verslagen van Landbouwkundige Onderzoekingen der Rijkslandbouwproefstation*, No. 23, pp. 57-78, figs. 5. The Hague, 1919.

The result of previous researches suggested to the author the convenience of determining the velocity of solution of phosphoric anhydride, preferably through repeated extractions (1). Through an adjustment of his own apparatus he could submit to continued extraction the phosphates under study; thus he was able to estimate the rate of solubility of phosphoric anhydride in carbon dioxide solution. The powdery state of the material, however, prevented a constant rate of solubility, but although the method is not strictly scientific, a comparison may be made between the rates of solubility of the phosphoric anhydride of various phosphates.

The results of analysis show that the rate of speed at which phosphoric anydride, contained in the following materials, is dissolved in carbonated water, decreases in the order in which the materials are here named: — Merck's tricalcic phosphate, bone meal, Algerian phosphate, 3 basic slag, 3 basic phosphates and Florida phosphate, another basic slag and "Ceres,, agricultural phosphate. These results are rather unusual, because the Algerian and Florida phosphates, which have a minimum solubility in 2 % citric acid, have a satisfactory rate of solubility in carbonated water, compared with other phosphates.

The opinion is held at present that the fertilising power of Algerian phosphate is much lower than that of basic slag, while that of Florida phosphate is almost nil. If, on the contrary, we were to base the fertilising power on the rate of solubility of the phosphoric anhydride in carbonated water, we should arrive at opposite conclusions and this points to the fact that either the commonly accepted opinion, from certain aspects, is wrong, or the criterion of the velocity of solution, at least as far as carbonated water is concerned, is not sound.

The necessity for fresh and accurate manuring experiments is obvious, and these according to the author, should be made in sand washed with boiling hydrochloric acid in order to eliminate interference from the many unknown factors existing in cultivated soils. Such experiments apart from determining which would be the best criterion to go by, be it the velocity of solubility, or the solubility itself independently of the former factor, would also serve to throw fresh light on the soundness, or

(1) *See R.* 1915, No. 1010. (*Ed.*)

otherwise, of WAGNER'S method based on the solubility in a 2 % citric acid solution of phosphoric anhydride contained in phosphatic materials compared with that in carbon dioxide solution.

302 – **Agricultural Consumption of Sulphate of Ammonia and Nitrate of Soda in the United Kingdom.** — Sulphate of Ammonia Association, Annual Report, in *The Chemical Trade Journal*, Vol. LXVI, No. 1703, pp. 37-38. London, Jan. 10, 1920.

According to the Fertilisers Allocation Committee of the Food. Production Department we have the following data on the development, during the war, in the consumption of nitrogenous mineral fertilisers in the United Kingdom:

Agricultural consumption of nitrogenous fertilisers in the United Kingdom (in tons).

Year	Production of Ammonia as Sulphate of Ammonia	Production of Sulphate of Ammonia as such	Sulphate of Ammonia Exported	Agricultural Consumption of Sulphate of Ammonia	Agricultural Consumption of Nitrate of Soda
1913 . . .	432 600	(1) 372 000	324 700	(1) 40 000	(1) 80 000
1914	426 400	(1) 363 000	313 900	(1) 50 000	(1) 80 000
1915 . . .	426 300	(1) 350 000	294 300	(1) 64 000	(1) 40 000
(2) 1916 . . .	433 700	312 500	160 300	144 600	(1) 5 000
(2) 1917 . .	458 600	283 500	28 500	234 000	(1) 5 000
(2) 1918 . . .	432 600	331 500	38 400	269 000	(1) 10 000

(1) Estimated. — (2) Year commencing June 1.

It should be noted that the agricultural consumption of sulphate of ammonia steadily increased parallel with the decrease in the exports.

Of the 269 000 tons of sulphate of ammonia furnished to agriculture from June 1, 1918 to May 31, 1919, England and Wales consumed 166 500 tons, Scotland 67 500 tons and Ireland 35 000 tons (1).

303 – **Importance of the Sulphur Deposits of Tacna, Chile.** — *Commerce Reports*, No. 289, pp. 947-958. Washington, D. C., 1919.

Sulphur comprises about 71.2 per cent. of the total value of the mineral production of the Province of Tacna for 1916, and is in fact the most valuable single resource of the region. The sulphur mines of Tacna are among the most important in the world. The deposits are estimated at from 10 000 000 to 45 000 000 tons of sulphur.

The exploitation of these vast beds has been greatly hindered by lack of capital and proper transportation facilities. The use of sulphur in the paper manufacturing industry might attract capital from the United States and other countries, while the opening of the Arica-La Paz Railway has provided the necessary means of transport.

AGRICULTURAL BOTANY. CHEMISTRY AND PHYSIOLOGY OF PLANTS

304 – **Factors Influencing Vegetation in Hot Climates.** — I. Rivera, V., Per il Mezzogiorno. Extracted from the *Rivista di Biologia*, Vol. I, No. 2, pp. 9. Roma, 1919. — II. Id. I problemi agrari del mezzogiorno. *Memorie della R. Stazione di patologia vegetale*, pp. 18. Rome, 1919.

Soil productiveness in Southern Italy is a question of climate, which is particularly hostile, through its inconstancy, to green crops, rather than a matter of soil fertility, which sometimes is all that could be desired. Generous manuring, which in the northern Italian districts largely increases the yield, may cause a decrease in the south in a dry year. The application of fertilisers containing nitrogen in a mineral form may in certain years aggravate the consequences of drought and of excessive heat, etc., by causing the drooping and drying up of the aerial organs of the plant (" wilt " of the American agriculturists).

The practices which have brought wealth to the northern Italian districts cannot be generalised in the south, where such unfavourable and uncertain conditions prevail; the question is to find out new and suitable methods, but the problem is not yet solved and in the majority of cases no initiative has yet been taken.

The green crops generally and cereals in particular are connected with the unequal distribution over the surface of the globes of the 2 principal factors in plant life, water and light; they, therefore, should find in southern Italy conditions favouring their production, but the author points out that this belief is destroyed by an analysis of the average wheat yield expressed in quintals per hectare in the wheat-growing countries of the world. The average yield per hectare appreciably decreases with a decrease of the latitude and increases with it. Against the lowest yields in Tunis, where the average of 5 years is 3.4 quintals per hectare, there are the 31.7 quintals in Denmark. Italy shows 14.5 in the north, 9 in the centre, 8.5 in the south and on the islands. What is then the cause of the greater productivity of northern countries? It seems certain that the reason must be found in the existence of certain influences, which change gradually from the equator to the pole.

The factors which favour the photosynthetic activity of the plant's green organs can be summed up as the influence of luminosity, and as this varies with the angle of incidence of the sun's rays and the clearness of the sky, one would be inclined to conclude that photosynthetic activity and production would consequently be greater in Southern countries where luminosity is more intense. This is not so: the author conducted experiments with wheat and maize and it seems that, particularly for wheat, greater luminosity causes a decrease rather than an increase in the yield; the carbohydrates stored in the plants seem to depend more on the number of hours of sunshine enjoyed by the plant, than on luminous intensity. This luminosity, which in southern climates is constantly accompanied by great heat during summer, even limits assimilation, which is the source of production.

Southern countries are not suited for herbaceous crops, and it is necessary to look for more suitable crops and not to persist in growing crops that cannot thrive.

The author expresses the hope that the Institute of Genetics created to deal specially with cereals in Italy may not limit its programme to grain crops alone, which in Southern Italy have neither a scientific, nor an economic basis. Researches should also be initiated and directed to find other crops, even more profitable than wheat, which would be benefited by the strong sunshine in these countries.

305 – **Folk-lore and Use Made of Ferns.** — PRINCE ROLAND BONAPARTE, (membre de l'Institut). in *La Nature, Revue des Sciences et de leurs applications à l'Industrie*, No. 2387. Paris, Dec. 27 1919.

During the late war fresh interest was evinced in ferns as regards the place they might fill in the national and domestic economy. The uses that Pteridophytae may be put to are not as manifold as those of the Phanerogams, nevertheless a number of instances of their usefulness are recorded. Lately Mr. MAXON of Washington published an account of the use that ferns are put to in America.

It is known that several tree-ferns of the genera *Cibotium, Balantium, Dicksonia* carry round their butt and at the base of their leaves hollow hairs which have the faculty of absorbing liquids; for this reason they have been employed to stop bleeding. These hairs come from various countries and are known under the general name of *Cibotium* hairs.

In the old pharmacopoeias the oldest known of these remedies was called the "Lamb of Scithya". It is " the Barometz " or Pengawar-Djambi of the Hindoos, which is obtained from *Cibotium Barometz* J. Smith, quite common in India, Java, China and Cochin-China. The most employed of late is the Paku-Kidang of Java furnished by the *Dicksonia Blumei* Moore. It is like a ball of tangled hairs; often the hairs are free, 2 inches long, light yellow or very brown.

According to Father CADIÉRE the use of " barometz " is known in Annam. When an Annamite wood-cutter cuts himself with his axe or bill-hook he rushes to the bank of the nearest torrent for a plant of *Ciborium Barometz* J. Smith. He takes the beautiful golden yellow, silky tuft which sorrounds the bud at the apex and with it dresses the cut to stop bleeding.

LOURRIERO, in his *Flora Cochinchinensis*, makes extensive reference to this plant and its use. Through the scarcity of straw for litter, attention was drawn to the common bracken *Pteris aquilina*. For this purpose it might be gathered in the months of July and August; good manure could be obtained from it. because of the amount of potash it contains.

In the north of England it was the peasants' custom in certain districts to burn ferns and to make balls from the ashes that took the place of soap. This species of fern is most plentiful in France; it could be cut several times in the year, and the leaves fed to horses and cattle. It might be used in the trenches, because it does not easily get soaked and keeps sweet. The peasants of certain French districts prefer mattresses filled with ferns for their children to sleep on, believing in the fern's healing power for certain ailments. The cost of procuring this fern would al-

most be limited to that of cutting and carting, because in most places nobody considers it of any value. Other uses have been suggested for it.

The rhizome of *Pteridium aquilinum* Kuhn var. *esculenta* Forster is eaten in many countries. According to BAILY the *Platicerium grande* J. Smith, of Australia yields sugar. M. J. CLAESSEN tells us that the natives of the Belgian Congo get salt from *Diplazium silvaticum* Swartz. Father CADIÈRE reports on a variety of uses that ferns are put to in northern Annam, some of which are given betow:

The natives make with wire or bamboo rough shapes of people, birds, beast, houses, tc. They place on these the tufty rhizomes of *Davallia bullata* Wallich, which at the proper season shoot up and the foliage gives the object a most fantastic appearance. These droll curiosities are a new industry of the Annamites and there is quite a considerable export of them to England and America.

The Annamites eat the young shoots of *Diplazium esculentum* Swartz; they boil them in water like asparagus, pickle or fry them; some hold the belief that they cause fever.

The *Stenochlaena palustris* Beddome, has very long and tough rhizomes that last well in sea water; they are marketed in large bundles.

The *Adiantum flabellatum* Linnaeus, is called by the Annam natives the incense stick plant, because of the shiny black, ebonyl ike colour of the rachis. With the leaves they dress cut wounds.

They use the bark of *Gleichenia linearis* Clarke, which is tough and has a beautiful shiny brown colour, to hem the brims of their hats. The whole plant is used for the silk-worm to climb and to make rough partitions in the stables.

They consider the large rhizomes of *Polypodium coronans* Wallich cooked on embers, excellent against stomach troubles.

The *Acrostichum aureum* Linnaeus is of great economic utility to the Annamites. The fronds of this fern, when dry, get hard and parchment like; thatches are made with them for the roofs of their houses. The cost of these thatched roofs is higher than that of the straw thatches, but the roof lasts longer and, above all, the danger of fire is much less. These fern leaves burn quickly, leave a very small quantity of light ashes, which quickly cool down, or blow away before setting fire to the whole of the house and the furniture; when the straw thatches on the contrary, and these take fire, everything is lost. Gathering these fronds and making thatches is the industry of certain villages.

The *Platycerium coronarium* Desvaux, is called the devil's box by the Annamites who worship or rather fear it. Its barren leaves climb up and round the trunk of the tree on which it grows; the ribbons hanging all round give the whole effect the appearance of a mysterious sunshade, suggesting the abode of some redoubtable genius. When they come across one of these *Platycerium*, they never fell the tree that supports it, even if it be the best tree in the forest, but they turn their heads away out of regard for, or perhaps from fear of offending the genius. Although this plant is met with frequently enough in the forest, Father

CADIÈRE never succeeded in getting an Annamite to show him a specimen. The plant is taboo and the profanation would bring evil on the transgressing native.

The stem of *Lygodium* supplies a binding material sufficiently strong, but not durable. Fishermen place a bundle of *Lygodium* in their nets to check the struggles of the fish inside.

Here the author ends his first account of the uses and folk-lore of Pterydophytes, which he intends to continue later, inspired in his work by that of M. ROLLAND on the popular flora of France.

306 - **Effect of Certain Organic Substances on Plants.** — CIAMICIAN, G. and RAVENNA, C. in *Gazzetta chimica italiana*, Year XLIX, Part II, vol. III and IV, pp. 83-126, figs. 20 + 2 tables Rome, 1919.

The authors studied in previous experiments (1) the influence that certain organic substances have on germination and particularly on the development of plants; they also dealt with the changes, especially auto-oxidisations, to which certain compounds are subject through the action of catalysts contained in plants. The work now under review concerns another set of experiments : in its first part they investigate the action of some more organic substances on plant growth; in the second part they deal further with the question of auto-oxidisation.

Young French beans plants were selected for the experiments, and grown on cotton wool ; this was daily moistened either with solutions of the substances which were the object of experiment, or twice a week alternately with a nutritive solution. The influence of the various solutions on the assimilation process was investigated by noting the distribution of starch in the leaves. To this end certain leaves were partially covered in the evening with a strip of black paper, so as to show up the coloration of the portions not covered ; on the following day they were collected during the hours of the most intense luminosity, dipped for a moment in boiling water, decolorised with alcohol and finally treated with a solution of iodine and potassium iodide. The starch completely disappeared from the covered portions of the leaves, if the leaves were in normal condition ; but if these were not under normal conditions or were at all sickly, the starch did not disappear altogether. By the system adopted, any alteration which the leaves had suffered was made manifest.

The substances tested and their effect on the plant were :

Monomethylamine. — Poisoning effects, though not very pronounced.

Dimethylamine. — Poisoning effects more pronounced than with monomethylamine.

Trimethylamine. — Stronger and swifter poisonous action than that shown by the two other amines ; it manifests itself in the drying up of the leaves.

Isoamylamine. — The first simple leaves dry up rapidly ; the first compound leaves appeared almost deprived of chlorophyll and soon withered.

(1) See *R.*, Dec. 1917, No. 1136 ; *R.*, Apr., 1918, No. 853 ; *R.*, Jan., 1919, No. 30. (*Ed.*)

Tartarate of tetraethylammonium. — Plants took on a peculiar appearance; slight poisonous effects.

Ammonium salts. — Normal development.

Urea. — Vigourous growth.

Guanadine. — The young plants were evidently sick; leaves faded first, then stems drooped.

Cyanamide. — Remarkable effects of poisoning; leaves fade, and growth suffers a check.

Potassium cyanate. — Growth is checked, the leaves become wrinkled; and then stems begin to droop.

Potassium cyanide. — Growth is delayed; leaves wrinkle and fade, stems remain erect.

Potassium salicylate. — It causes some delay in the growth of plants, but these reach the flowering stage and ripen some of the seeds.

Methyl salicylate. — Poisonous effect is quite plain; it manifests itself after the appearance of the second compound leaves.

Pyrocatechin. — Plants quickly show ailing symptoms, but live on though very poorly.

Guaiacol. — Growth stops when the first compound leaves are about to appear, and the young plants die off shortly after.

Aniline. — Remarkable poisoning effects manifesting themselves in the leaves; growth is checked a few days after the first treatment.

Acetanilide. — Leaves turn yellow, stems become soft, growth is checked. Plants begin to decline sooner than is the case with aniline treatment.

Methylacetanilide (Exalgine). — Poisoning effects similar to those caused by acetanilide, though more pronounced.

Indole. — Stems wither, the young plants droop and die off quickly.

Methylindole. — Effects similar to those caused by indole, though not so swift, perhaps because methylindole is sparingly soluble.

Pyridine. — Normal vigorous growth.

Piperidine. — Slight check of growth; leaves show a few yellowish spots, but the young plants go on growing vigorously enough.

Methylpiperidine. — Remarkable poisoning effects manifesting themselves through blotches on the leaves and recumbent stems.

Acetyl-piperidine. — Manifestation of poisoning effects through the fading of the leaves; stems remain upright.

Piperine. — Effects not unlike these produced by methylpiperidine; leaves fade and stems droop.

Conine. — The young plants soon start ailing; leaves dry up, but stems continue to stand straight.

Tartarate of dimethyl-piperylammonium. — Peculiar appearance of the plants similar to that caused by other quarternary bases, though less pronounced. Limited poisonous effects.

Nicotine. — Withering of the simple leaves, albinism of the first compound leaves.

Morphine. — Effects of poisoning not very remarkable.

Codeïne. — Poisoning effects more pronounced than in the case of morphine; many blotches cover the leaves which dry up.

Heroïn. — Remarkable effects of poisoning on the leaves, which turn yellow.

Papaverine. — The young plants gradually wither; leaves dry up round the margin.

Narcotine. — Effects similar to those caused by papaverine.

Cocaïne. — Leaves become covered with brown blotches, the young plants die off before the growth of compound leaves.

Atropine. — Leaves first get wrinkled, then full of spots. The more advanced young plants are very sickly, nevertheless some of them reach the flowering stage.

Sparteïne. — Leaves become full of brown blotches and dry up quickly.

Caffeïne. — Leaves become covered with yellow spots and dry up rapidly.

Theobromine. — Poisonous effects not very pronounced, which are made manifest through the albinism of the simple leaves.

Methlyl-uric acid. — Limited poisoning effects; the first symptoms manifest themselves after the emission of the second compound leaves.

Uric acid. — Vigorous development.

Quinine. — Vegetation is checked, leaves become wrinkled, stems droop.

Cinchonine. — Although less remarkable, poisoning effects are similar to those caused by quinine.

Strychnine. — Growth is checked when the second compound leaves make their appearance.

The results above reported led the authors to the following conclusions: — Methyl-radicals, far from having a protective influence on the reactive groups such as hydroxyls, amino and imino groups heighten the action of the fundamental substances that contain them. Methyl groups are not the only ones, which modify the action of organic compounds on the plants experimented upon, as other radicals manifest an action of their own, *i. e.* the propyl radical of conine, the acetyl in acetyl-piperidine acetyl-morphine and acetanilide and again the radical of the piperinic acid in piperine.

One is led to believe that plants start from the simplest fundamental compounds and that they combine with alkyl or acid groups and lateral chains detailed to special functions.

The poisonous substances experimented with, interfere in certain cases with the formation as well as the migration of starch; the leaf treated with iodine reagent takes on a peculiar and different appearance in each case of inhibition.

The experiments described in the second part aimed principally at comparing the oxidisations determined by plant enzymes with those which Ciamician and Silber produced by the action of light (*Memorie della R. Accademia delle Scienze dell'Istituto di Bologna*, Series VI, Vol. IX, pp. 168; Series VII, Vol. II, p. 188; 1914-1915). A mash made with spinach was

mixed with the water solution of the substance under study ; the mixture was left for a while to stand and submitted to a slow current of oxygen. In a water extract of the mixture were sought the newly formed bodies.

It was noted that in general the oxidisations caused by light and those caused by enzymes are not the same ; thus toluol, which through the action of light yields benzoic acid, by auto-oxidisation undergoes no change through the action of enzymes in spinach leaves. Among the acids that were examined, oxalic acid is almost entirely oxidised through the action of light and through that of enzymes. Succinic acid under the influence of light yields small quantities of glyoxal together with acetic aldehyde, acetic and propionic acids ; through the action of enzymes, succinic acid produces neither glyoxal nor volatile acids but only acetic aldehyde, while a portion of it is changed into a compound that emulsin can split. Lactic acid undergoes auto-oxidisation through the action of light and gives aldehyde and acetic acid; with the enzymes, lactic acid produces only the aldehyde. Light causes the auto-oxidisation of mandelic acid, which yields benzoic and salicylic aldehydes ; but the enzymes transform mandelic acid almost completely in a compound, which after hydrolysis with sulphuric acid, produces mandelic acid once more.

The action of light and also oxygen change coumarin into its dimerous form, the hydrocoumarin of Dyson ; this polarisation does not take place with spinach enzymes.

Amongst the ketones, acetone and probably also methylethylketone behave in a similar way under the influence of light or of the enzymes. The difference between the two agents was most marked when cycloketones were employed ; *i. e.* cyclo-hexanone, the isomerous 3 methyl-cyclohexanones and menthone. Light in these three cases is accountable for the hydrolysis which produces the respective fatty acids and for the oxidisation leading to the dibasic or ketonic acids corresponding to the ketone employed. With the enzymes, on the contrary, the authors could never obtain the dibasic acids corresponding to the ketone employed, but they always obtained lower fatty acids, butyric, propionic, acetic, and formic acids. Small quantities of succinic acid were also identified among the oxidisation products of menthone and meta-methyl-cyclohexanone. It is confirmed therefore that the enzymes of spinach leaves have an selective oxidising action which sometimes remains in abeyance, and in other cases goes further than that caused by light.

In living plants the oxidisation is more energetic than that produced by enzymes, which are active even in dead leaves. Substances, in fact, that greatly resist oxidisation, such as pyridine and benzoic acid, after inoculation in a maize or tobacco plant, are found but in small quantities in the extract made from them, while spinach enzymes in presence of oxygen do not affect them.

The energetic oxidising faculty of plants, especially that of living plants cannot be attributed to the known oxidases, but more probably to protoplasmic enzymes insoluble in water and to all appearances insoluble in glycerine These statements prove that plants have a very efficient way

of eliminating waste organic products, viz., oxidisation. If in some of them certain substances are found which are termed accessory, such as glucosides, alkaloids, etc., these bodies cannot be regarded as waste products, because plants would not, eventually, lack the means for their elimination.

307 – **On the Biological Meaning of Tannic Bodies. Variations of Tannin Content in the Bark of Chestnut tree According to Months and Seasons.** — De Dominicis, A., in *Le Stazioni sperimentali agrarie italiane*, Vol. I,II, pp. 305-311. Modena, 1919.

The author reviews the controversial opinions concerning the biological meaning of tannic substances in plants; he relates his own experiments and observations on the bark of chestnut trees consisting in the determination of the content of tannin at various ages and in various months of the year and dwells on the influence of acids on the coagulation of the white of egg through the agency of tannin. He also discusses a number of facts for the interpretation of the results of his own experiments in relation to those obtained by others, and reaches the following conclusions:

As regards their origin, constitution, physical and chemical properties, tannic bodies are of the nature of glucosides. The esterification takes place between a more or less simple or complex aromatic oxyacid of fundamentally gallic and protocatechic type and a sugar, which, more frequently than not, is glucose. Biogenetic, synthetic as well as optical reasons prove this assertion.

Tannin is a strong poison for protoplasm because it is an energetic coagulant of albumin; on the other hand we see it appear, increase and remain during the germination of seeds that first contained none of it. Tannin therefore is not a reserve-substance stored up, either for the sugar that it contains, or for those compounds, which of themselves would be injurious, were they to accumulate in a free state. Tannic substances should be considered secondary products of metabolism. This interpretation with regard to tannin cannot be extended to the esterification of phenolcarbonic acids, which represent the nucleus of tannic substances. The same biologic reason does not apply to the formation of other glucosides, that is, to the neutralisation of the toxic properties of the products of plants metabolism. Gallotannic acid, in fact, is more toxic than gallic acid.

Tannin is readily absorbed by wood, gallic acid hardly at all. The easier elimination of tannic bodies in the form of glucosides, through the absorbing action of the cellulose of the wood, is not the only, nor the principal reason for their formation. Firstly, if the tannin absorbed became an intimate part of the substance of the wood, it could not be extracted by water; secondly no explanation is offered with regard to the cycle and destination of tannic bodies in plants and in their non-ligneous organs.

The results obtained by the author suggest the following explanation:— The principal reason for the formation of tannic glucosides is that these are more readily oxidised than the phenolcarbonic acid from which they are derived. Tannin in fact burns more easily than gallic acid. This is

a very important reason when viewed in connection with plants, which are without excreting organs, because it provides a means whereby plants can get rid of products, some of which are very poisonous. Thus tannin is eliminated from fleshy fruits through complete self-oxidisation, when its coagulating energy is no longer neutralised by the stabilising action of the free organic acids, which gradually disappear with the progress towards maturation. In other organs the tannin formed, or migrated thereto, is balanced by that which combustion destroys. In the case of a peripheral organ, such as the bark, directly exposed to atmospheric oxygen and to atmospheric changes, that balance is liable to be affected, as for instance, when the oxidisation of tannin increases as the temperature rises, reaching its maximum in summer's hottest months.

Tannic substances in the form of glucosides represent a waste product which the plant easily destroys, but it utilises the combustion process for vital purposes.

308 – **Relative Resistance of Various Crops to Alkali.** — HARRIS, F. S. and PITTMAN, D. W., in *Bulletin* No, 168, *Utah Agricultural College Experiment Station*, pp. 1-23 + 69 fig. Logan (Utah), July, 1919.

Different plants show considerable variation in their resistance to soil alkali. Some wild plants grow only where the salt content is high. On the other hand, most cultivated plants suffer continually in the presence of very large quantities of soluble salts ; there are a few exceptions to this rule, e. g., the date palm.

In many of the arid regions of the world the presence of alkali is one of the chief obstacles to the development of agriculture.

Between tracts completely free from alkali and those where the salt concentration is such as to prevent crops, there are very large zones of intermediate character where it is possible to introduce crops relatively less sensitive to the injurious action of alkali. The experiments described in the Bulletin under review were made with the object of studying the germination and growth of various crops in alkali soil ; they dealt with numerous species of cultivated plants and several varieties of each species.

Glass vessels were used filled with a calcareous loam soil of the " Greenville loam " series, in which the concentration of certain salts was varied. In each vessel 10 seeds were sown. Three weeks after the plants came up, they were harvested and the dry weight determined as a measure of the total growth.

SALTS USED. — Sodium chloride, sodium carbonate, and sodium sulphate in the concentrations indicated in the adjoining Table.

CROPS TESTED : — 14 varieties of oats, 8 varieties of wheat, 3 varieties of barley, rye, 7 varieties of maize, 3 varieties of millet, 5 varieties of sorghum, 8 tpes of forage legumes, 4 varieties of beans, 7 varieties of fodder grasses, 5 kinds of vegetables sugar beet, buckwheat, hemp, flax, rape.

The different varieties of oats did not show any great difference in their resistance : — *Boswell Winter*, *Red Rust Proof*, *Black* and *White Tartar*, and *Colorado No.* 9 were slightly less resistant than the others. The lower

Concentration of salts used (in millionth parts of dry soil).

Number	Sodium chloride	Sodium carbonate	Sodium sulphate
1.	—	—	—
2.	333	666	1 000
3.	666	1 333	2 000
4.	1 000	2 000	3 000
5.	1 500	3 000	4 500
6.	2 000	4 000	6 000
7.	2 500	5 000	7 500
8.	3 000	6 000	9 000
9.	3 500	7 000	10 500
10.	4 000	8 000	12 500

concentrations of salts stimulated growth, and this stimulation continued up to 1000 millionths for the chloride, 2000 for the carbonate and 3000 for the sulphate. Above these limits the number of plants obtained and their growth declined rapidly.

For wheat, similar conditions as for oats were observed. *Turkey Red* was the most resistant and *Velvet Don* the least resistant.

Among the varieties of barley tested *Black Hulless* was the most resistant and *Utah Winter* the least.

Only one variety of rye was tested and it showed itself very resistant.

The maize showed effects of toxicity at low concentrations but was, however, resistant and was able to grow considerably even at very high concentrations. In comparison with other crops it seemed to be more sensitive to the action of sodium chloride than to that of the sulphate or carbonate. Millet showed similar resistance to maize.

Among the varieties of sorghum tested, *Collier's* showed itself most resistant, and *Milo Maize* the least so. *Vicia villosa* showed tolerance for chloride.

The growth of alfalfa ceased at a concentration slightly lower than that required for stopping the growth of *Melilotus alba*.

Of the grasses, the rye grasses were the most resistant though very sensitive; *Poa pratensis* was the least tolerant and is extremely sensitive: *Dactylis glomerata* was only slightly more resistant.

Rape was more resistant to chloride than to carbonate and sulphate; on the other hand, sugar beets were stimulated by low concentrations of carbonate, but injured by chloride and still more by sulphate of sodium.

Kohl rabi was very resistant to sulphate at low concentrations but was very sensitive to carbonate even of low concentration, and a concentration over 3000 millionths stopped growth. Taken altogether the data collected lead to the conclusion that the application of salts at concentrations higher than 4000 millionths for chloride, 8000 for carbonate and 12 000 for sulphate is injurious for ordinary crops. These figures would have

to be modified if they were obtained from analysis of alkali soil, since the relation between alkaline chlorides and carbonates is not the same for "salts added" to the soil as for "salts extracted" from the soil.

In any case in land rich in salts the most suitable crops are cereals and the least suitable forage grasses. Of the forage crops may be recommended:— Vetches, *Melilotus alba*, alfalfa, and *Vigna Catjang*, but Timothy grass and Alsike clover are not be advisable.

309 – **Influence of the Soil and Manure on the Nitrogen and Ash Content in Crops.** — MASCHHAUPT I. G. (Rijkslandbouwproefstation te Gronigen), in *Verslagen van Lanbowkundige Onderzoekingen der Rijkslandbouwproefstations*, No. 23, pp. 40-54. The Hague, 1919.

Results for the year 1917 of the experiments started in 1909; the results up to 1916 have already been reported (1).

It is confirmed that phosphoric anhydride used as a fertiliser is little, if at all, utilised by plants on reclaimed land: the reasons of this interesting question will be the subject of further researches.

The corroboration of previous analytical data with regard to potatoes confirms the fact that systematic ash analyses makes evident the relation between the nature of the soil and the composition of the plants grown in it. This is important from the soil science and from the manurial point of view.

It is to be borne in mind that the influence of manuring on the plant ash may be properly estimated only when crops do not differ much as to the time of their harvest and as to the quantity of their yield.

PLANT BREEDING

310 – **On the Behaviour of Hybrids Resulting from the Crossing of a Mutant with the Original Variety** — FRUWIRTH, C., in *Zeitschrift für Pflanzenzuchtung*, Vol. VII, No. 1, pp 66-73. Berlin, June 1919.

The author reports on some crosses between a mutant and the variety from which it originated by mutation.

Lupinus angustifolius has seeds with brown-black, grey-green and light brown, marbled tints due to brown pigment held in a certain part of the spermoderm. The thicker the pigment-layer, the darker and more evident the marbled patches.

In 1909 the author picked out a plant of *Lupinus angustifolius* with 4 seeds of uniform grey-greenish tint. There are other seeds on the same plant with hardly noticeable patches and it was believed at first that these were ordinary instances of modifications or fluctuations, but the behaviour of the progeny and, more so, that of certain hybrids between the "variants" and the original form revealed the difference existing in the genetic composition.

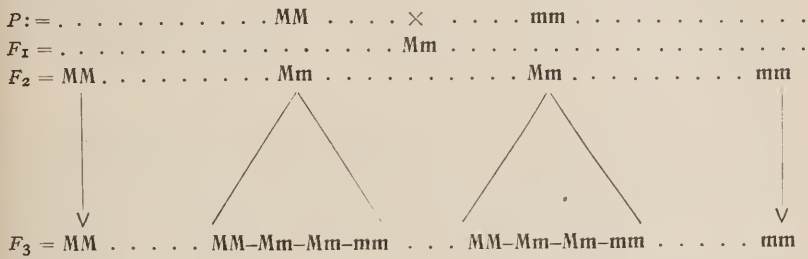
The normal type would have, besides the determinant F responsible for the spermoderm coloring in general, also the factor M because this is accountable for the distribution of the pigment itself, to which are due the peculiar marbled patches.

(1) See *R.*, 1919, No. 579. (*Ed.*)

The normal type would have the gametic formula FF MM; in the "variant" seeds, on the contrary, the factor M is lost and the formula FF mm woould express the issue.

The presence or absence of the factor M is responsible for the difference, therefore when studying hybrids between the variant and the original form, we should solely refer to this factor.

The following is the plan for F_1, F_2, and F_3 of the cross between lupin with marbled seeds (original form = MM) and the lupin with seeds of uniform tint (variant = mm).



The composition and nature of the descendants, on the whole, are are those corresponding to a monohybrid as shewn on the above plan.

Nevertheless in many cases there are exceptions to the rule and the following may be quoted: —

1) The "marbled" character is dominant in F_1 when the female parent is marbled; it is recessive when the female parent is of uniform tint. This occurs in spite of the composition Mm identical in both.

2) The dissociation in F_2 takes place without exception in all hybrids of the F_1, whether marbled or of uniform tint (constitution mm: see later).

3) In the successive, plants up to F_6, with marbled seeds may either dissociate or keep constant through their progeny; but it may happen that certain plants with the marbled seed character keep constant according to the plan, while others dissociate against all expectations.

4) Plants with marbled seeds may keep constant through one generation, dissociate in the next, and afterwards become constant again.

5) Plants with seeds of uniform and constant tint (the result of dissociation) may dissociate in 2 generations, then become constant through the successive issues.

6) In certain cases there is no rule concerning the numerical proportion of dissociation; there may be prevalence of plants with seeds having uniform tint, or there may be prevalence of the one or of the other type alternately.

These departures from the rule might be explained in the following manner: —

A) With regard to the predominance of the female parent's character, there may be 2 alternatives; —

a) M, being the male parent's progeny, has no influence on th combination M m and is completely separated from m, thus having M ! m

b) Spontaneous change, because factor M, is inactive when issue from the paternal side.

B) First generation hybrids have always the formula M m. I the case though of M ! m the issuing hybrid will have uniform tint, as i its composition were m m; while in M m, on the contrary, the issuin hybrids will be marbled with M dominant. In F_2 there will occur in bot cases identical dissociations.

C) Considering that a plant M ! m presents itself as m m, it is nc surprising if, from individuals having seeds of uniform tint and the appa rent constitution m m, but really with M n constitution, will give disso ciated descendants.

D) At times, the normal association of the determinants remain through one generation, but is discontinued in some individuals in the ge nerations after that: thus the passage from M m to M ! m, or from M ! n to M m will explain the irregularities quoted in paragraphs 4 and 5.

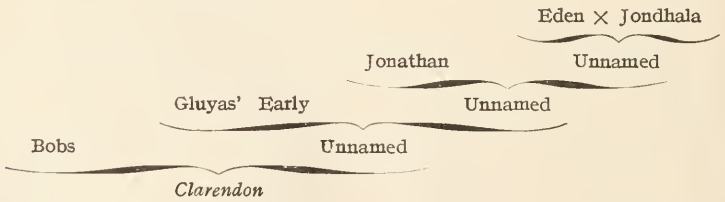
E) The possible irregularities referred to above will explain th absence of any numerical order at times connected with character disso ciation through successive generations of hybrids derived from the cros of a mutant with the original form.

In conclusion, by crossing a mutant formed through the loss o the determinant M alone, a monohybrid is obtained, the descendants o which can be explained on the main lines of a monohybrid plan. There are however, numerous cases that do not fall within the bounds of this plan an in all likelihood, such cases are due to spontaneous changes in M, or t the existence of differentiated groups M ! m and M m.

311 – **Australian Varieties of Wheat Obtained by Hybridisation and Selectio** — PRIDHAM, J. T., in *The Agricultural Gazette of New South Wales*, Vol. XXX, Part. pp. 641-642 + 2 figs. Sydney, Sept., 1919.

Description of 3 varieties of wheat obtained by crossing and selection: – Clarendon, Hard Federation, and Warden.

CLARENDON. — The pedigree is as follows :—



Matures early: straw fairly tall, white and not very strong. Ear erec slightly awned at the tip, fairly open; glumes long and pointed; gra white, medium hard, in quality slightly superior to Canberra.

Clarendon wheat is resistant to rust, partly owing to immuni inherited from its ancestor Gluyas Early and partly owing to its earlines It is less liable to lodge than Canberra.

HARD FEDERATION :— Obtained by selection from Federation (which is believed to be the product of a natural cross), and from which it is distinguished by the ears being less dense, ; early ripening (a week earlier) ; vigour and development of the culms which, although slightly less robust than those of its ancestor, are little liable to lodging. The grain, hard and heavy, contains 11 % of gluten. Hard Federation grows well in the western and south-western districts ; in the southern districts, however, its yield is less than that of Federation.

WARDEN — The result of a cross made by PYE at Dookie College, Victoria. Its pedigree is : —

Quartz × Wards' White

Unnamed × Bordeaux rouge

Warden

It is *par excellence* a forage wheat. It remains green for a long time. Ear white, erect, pointed, open ; glumes firmly attached, grain soft, elongated, pale red. It yields abundantly and is easily threshed.

312 – **Experiments in Hybridisation Between Certain Kinds of Wheat in New South Wales, Australia.** — PRIDHAM, J. T., in *The Agricultural Gazette of New South Wales*, Vol. XXX, Part. 9, pp. 625-626 + fig. 2. Sydney, Sept., 1919.

The Federation variety of wheat is characterised by its high yield and by the robustness and fine growth of its straw ; its grain is of excellent quality.

The Cowra No. 15 variety, with somewhat complicated pedigree, has broad, dense (compact) ears, straw of medium height and an erect habit until the harvest ; its grain has slight defects in quality and structure.

The author undertook, in 1914, the cross *Federation* × *Cowra* No. 15 with the object of combining the qualities and type of grain belonging to the variety Federation with the excellent characters of Cowra No. 15. The experiment is in progress ; the F_5 generation has already been reached ; some of the selections have a brown ear like Federation, others on the other hand a white ear like Cowra No. 15, but the great majority have brown ears indicating the dominance of Federation.

The author proposes to continue his experiments with the object of isolating types and forms in which the desired characters are combined in the best proportions and in a homozygous state.

Both Cowra N° 15 and Cowra N° 19 belong to the group of FARRER crossbreeds. In 1916 these two varieties were crossed with the object of obtaining an early or moderately early type, with grain of medium soft character. As in the previous case a large number of forms was obtained and it is hoped to isolate some with the desired genetic constitution.

313 – **Synthetic Production, by Selection and Crossing of Varieties of Maize Very Rich in Gluten, in the United States.** — HAYES, H. K. and GARBER, R. J., in *Journal of the American Society of Agronomy*, Vol. II, No. 8, pp. 309-318 + 1 pl. Washington D. C., Nov, 1919.

Results of a series of experiments carried out at the Minnesota Agricultural Experiment Station, commencing in 1915, with the

object of creating a type of *Minnesota* No. 13 maize with a high protein content.

The experiment commenced with the self-fertilisation of a certain number of ears and the determination of the protein content of each; the ears with the highest protein content were used as parents for many lines: it was determined experimentally which of these lines when crossed gave the best yields. The best yielding cross was then sown in an isolated plot and selected for vigour. The results so far obtained show that the method is reliable.

In 1918, self-fertilised ears were obtained from F_1 crosses between high protein strains. A negative correlation exists between the number of grains per ear and the percentage of protein. Table I gives an idea of this correlation.

TABLE I. — *Correlation between "number of grains per ear" and "percentage of protein".*

Percentage of protein.

Number of grains per ear.	12.75	13.25	13.75	14.25	14.75	15.25	15.75	16.25	16.75	17.25	17.75	*Totals*
25	—	—	—	—	—	—	—	—	2	—	—	2
75	—	—	—	—	—	—	—	—	—	1	—	1
125	—	—	—	—	—	—	1	3	2	1	2	9
175	—	—	—	—	—	—	3	3	4	2	—	12
225	—	—	—	—	—	—	2	3	2	—	1	8
275	—	2	—	1	1	4	3	3	1	—	—	15
325	2	—	1	—	3	2	4	3	1	—	—	16
375	—	—	1	1	1	—	—	1	—	—	—	4
Totals	2	2	2	2	5	6	13	16	12	4	3	67

The correlation coefficient $r = -0.601 \pm 0.053$.

The effect of foreign pollen on the protein content, in the year in which a cross is made, is little or none, as is shown in Table II which gives the data relating to self-fertilised ears belonging to high and intermediate strains and the data relating to ears of the same strains crossed.

TABLE II. — *Average protein content in self-fertilised ears and in ears of crosses.*

Strain	Number of years self-fertilised	Average protein content
	4	14.92 %
	4	15.46
	4	16.76
	4	15.09
	4	12.97
	4	12.53
Average of 1 or 2 × 3 or 4	—	17.14
Average of 1 or 2 × 8 or 9	—	16.89

In all crosses high protein content hybrids were obtained, even when using pollen of relatively poor strains (Nos. 8 and 9 with 12.97 and 12.53 % respectively).

Table III compares some data showing that it is possible, by adopting the method proposed by the author, to obtain types of maize with percentages of protein higher than that of the original strain (in the case of *Minnesota No.* 13).

TABLE III. — *Comparison of protein contents in different types of maize.*

Strains and their crosses	Average protein content		
	in 1916	in 1917	in 1918
1	15.82 %	14.03 %	15.10 %
4	14.47	13.06	14.93
Minnesota No. 13 (original strain)	—	**10.17**	**10.25**
1 × 4 F_1 Ear *A*	—	—	12.25
1 × 4 F_1 Ear *B*	—	—	12.44
1 × 4 F_1 Ear *C*	—	—	12.81

In 1915, one hundred and twenty seven self-fertilised ears were obtained; 2 strains were isolated (Nos. 1 and 3) which had a much higher protein content than the normal, and these 2 strains preserved their characters unchanged during the period 1916-1918. In 1917, some crosses were made between these two strains and hybrids were obtained containing at least 2 % more protein than Minnesota No. 14. These crosses are also superior in yield to the original strains.

314 - **Improvement of Potatoes through Hybridisation and Selection of Bud Mutations.** — AUMIOT, J., in *Comptes rendus des Séances de l'Academie d'Agriculture de France*, Vol. V, Year 1919, No. 35, pp. 905-910. Paris, Nov. 19, 1919.

The author describes work carried out in 1919 aiming at the improvement of potatoes; his experiments included: — I) Rearing potato seedlings; II) crossing and hybridising; III) cultural bud mutations.

I) REARING POTATO SEEDLINGS. — Between April 9 and 13, the author sowed about 10 000 potato seeds in pots, keeping them on hot-beds and under frames. All these seeds were the results of crosses between cultivated varieties, others were the result of hybridisation between *Solanum Commersonii*, wild *S. Maglia* and *S. tuberosum*; a small number were the product of natural pollinisation; the experiments were therefore carried out with cross-breds and hybrids.

He obtained 3117 seedlings, which were all re-potted once and 483 of them were potted on a second time before being planted in the open. They struck roots in a most satisfactory manner. The young plants showed a remarkable hardiness and vigour during the long drought which preceded and followed the planting. Their growth was marvellous; the stems stood from 56 to nearly 61 inches high with a diameter of as much as four-fifths of an inch near the ground and carried numerous strong upright branches. The blossoming was gorgeous and lasted long; fruits were extremely plentiful. The crop was harvested at various dates, a start being made with the earlier varieties; the yield in a large number of cases corresponded to the vigorous growth. The seedlings originated from 24 crosses btween 10 varieties of cultivated potatoes and one hybrid: *S. Maglia S. tuberosum* var. Enowflack.

The vigour and productivity of cross-breds are infinitely greater than those originating from natural fertilisation and are all the greater as the characters of the parents differ. Since its introduction the potato has been propagated from tubers; this doubtless explains the extraordinary growth of cross-breds in which the effects of cross-breeding (heterozygosis) are added to those of the propagation by seed.

In the subjoined table some figures concerning the yield are given: —

Crosses	Number of tubers	Crop per plant	Weight of the heaviest tuber	Crop calculated at the rate of 33.000 plants
		kg.	gm.	kg.
Beurre × Maréchal Vaillant	70	2.730	152	89.090
Enowflack × Industrie	11	1.640	355	54.120
Beurre × Blanchard	61	1.802	90	59.466
Jaune d'or de Norvège × Beurre	—	1.750	76	57.750
Wonder of the World × Bolivienne 10 bis	40	1.667	139	55.010
Beurre × Bolivienne 10 bis	29	0.715	59	23.595
Enowflack × Beurre	28	0.860	110	28.380
Wonder of the World × Beurre	17	0.950	188	31.350

The author took into consideration other characters besides vigour and productivity, such as shape, colour of the skin and colour of the pulp. Several crosses with *Bolivienne* 10bis are proof against *Phytophthora infestans* even under really unfavourable conditions. *S. Maglia* × *S. tuberosum* var. Enowflack produces a hybrid with intermediate characters to those of the parents, although nearer to *S. tuberosum* than to *S. Maglia.*

II) Crossing and hybridising. — In 1919 the author made 1370 pollinisations and recorded 458 successful ones. The following varieties entered into the combinations : —

a) 15 *varieties cultivated in Europe :* —Industrie, Institut de Beauvais, Professor Maerker, President Krüger, Early Rose, Doctor Lucius, Beurre, Garibaldi, Reine des Farineuses, Géante Bleue, 1915 Seedling, (with long yellow tubers) Enowflack, Prince de Galles, La Tour d'Auvergne, Yellow Malta.

b) 3 *Bolivian varieties:* — Nos. 6, 10 *bis* and 17.

c) 1 mutant : *S. Commersonii* mutated in 1917.

d) 11 crosses of the year : Beurre × Marechal Vaillant, Beurre × Jaune de Norvège, Beurre × Blanchard, Beurre × Bolivienne 10*bis* Bolivienne 6 × Beurre, Blanchard × Enowflack, Blanchard × Beurre, Enowflack × Beurre, Enowflack × Bolivienne 10 *bis*, Enowflack × Bolivienne 17, Jaune d'or de Norvège × Beurre.

e) 1 *hybrid* : — *S. Maglia* × *S. tuberosum* var. Enowflack.

f) 3 *wild forms* : — *S. Maglia* Schlecht, *S. Commersonii* Dun., *S. Caldasii* Kunth.

g) 1 sort of doubtful origin : — *S. tuberosum* Sutton.

The author was prevented by mishaps and unfavourable circumstances from getting some very good varieties through to the bearing stage, but he is confident of doing so ; his material for experiments is rapidly increasing and later on he will resume his observations bearing on the genetic side.

III) Cultural bud mutations. — The experiments with mutations of tuber-bearing wild *Solanum* were extended to 200 potted plants. The observations confirmed those of previous years : — every row propagated by tuber, with the exception of some cases of retrogression, keeps the characters already acquired in its environment, or changes more and more in the mutative sense.

Number 25 (*S. Maglia* modified in 1916) has distinctly mutated to cultivated *S. tuberosum.* Its aerial and underground organ are those of the common potato. On September 13, growth being near its end, the plant was dug up, and had grown 6 small tubers on 3 very short stolons not longer than ¼ inch ; the tubers were of spheroidal or slightly elongated shape with shallow eyes, purple-red skin and white pulp.

Numbers 118, 119 and 120 *S. Commersonni C N E* have also produced " mutated " plants of beautiful appearance, healthy and even with well grouped tubers, oval or oblong, shallow eyes, yellow peel and white pulp.

The author obtained mutations that do satisfactorily under cultivation. the *S. Commersonii* mutated in 1915 and 1916 are disease-proof and yield

an average crop. Among them worthy of note is *S. Commersonii* (mutated in 1916) which is bound to take a prominent place among the varieties most largely grown ; its characteristics are:— vigour, immunity to disease, large crops ranging from 1 lb. 14 oz. to 3 lb. 14 oz. per plant, fair appearance, nice shape, good quality.

The author did not anticipate that good sorts coming well up to the agriculturist's expectations could be obtained starting from wild species with long threading stolons that carried small, non-edible tubers ; but experience shewed how this is possible by means of cultural bud mutations.

315 – **Investigations on the Variability and Heredity of the Characters of Certain to Species of *Lolium*.** — HESSING, V. in *Zeitschrift für Pflanzenzüchtung*, Vol. VII, No. I, pp. 53-57. Berlin, June, 1919.

Results of genetic and biometric investigations bearing on the variability and heredity of the characters of *Lolium italicum*, *L. italicum* var. *Westerwaldicum* and *L. perenne*.

Within the uncertain bounds of the species these plants have a great number of types and characters which, though relatively constant, largely overlap and are grouped in the most varied combinations.

The separation of varieties and of species itself is often impossible, because of such fluctuations ; take, for instance, *Lolium italicum ;* it has closed leaf-buds with laminae folded, while buds of *L. perenne* have rolled up leaves, though in many cases it is quite the reverse. There is uncertainty also with regard to the number of inflorescences, number of spikelets on the inflorescence, length and width of leaves, presence or absence of awns, length of haulms, etc :

HABIT OF GROWTH. — The author classifies into 3 groups the various habits of growth between which there are many intermediate forms :

a) Erect, V branched and fairly tall.

b) U shaped with larger and open stool.

c) Lower stool shaped almost like a rose.

They are conventionally distinguished thus : V = a ; U = b ; — = c.

Isolation and selection by pure lines proved that habit of growth is hereditary.

On a plot of *L. italicum* of the 0173 family, obtained from a U plant, out of 42 individuals 38 had the U habit ; out of 46 in the 0174 family the U type was reproduced in 42 ; finally in the family 0167 out of 55 plants 52 had the habit of growth of the parent U.

Similar results were obtained for the V type, thus 48, 54 and 56 plants, belonging respectively to the families 0227, 02230 and 0283, all issued from a V parent, plant (—), 46, 53 and 54 plants reproduced the V habit of growth.

As to (—) 55 individuals taken from family 0212 issued from a (—) parent and 53 out of that number inherited the (—) habit of growth.

WIDTH AND LENGTH OF LEAVES. — For *Lolium italicum* we have average maximum length 7.09 mm., the maximum being 9 and the minimum 5. Minimum average breadth was 3.6 with a maximum of 5 and a minimum of 2.5. mm. Maximum average length is 183 mm. with a maximum of 265

and a minimum of 120 mm. Average minimum length was 175 mm. with a maximum 195 and a minimum 101 mm.

For *L. perenne* the maximum average width is 3.09 mm. with a maximum 4 and a minimum 2 mm. The average length was 143 mm. with a maximum 255 and a minimum 115 mm.

Shape and measurement of ears. — Poor specimens often bear robust inflorescences which carry many flowers. Selection of these ears did not lead to a real improvement of the variety. In fact on a plot thus raised, the author obtained 68.5 % of weaklings, while out of one, on which no selection was made, the percentage was 47.63.

On many ears of *Lolium italicum* the glumes often change into spikelets, the ear thus becomlng branched. The author calls it " Ernärungsmodification " that is, a metabolic modification; nevertheless, he considers that under suitable conditions the tendency to reproduce this modification would be hereditary.

The ratio between the length of the floral axis and the number of spikelets, or in other words, the density of the ear, is also a most variable character. The following figures represent the calculated averages for *L. italicum :* —7.11 ; 8.96 ; 9.64 ; 12.64 ; 6.21 ; 11,65 ; 12.4 ; 12.11 ; 7.25 and 9.65 ; for 2 sorts of *L. italicum* var. *Westerwoldicum* the figures are 11.89 and 9.51 ; for *L. perenne* 9.3

316 – **Crosses between the French " Chevrier " Bean with Green Seeds and other Varieties.** — Von Tschermak, E., in *Zeitschrift fur Pflanzenzüchtung*, Vol. VII, No. 1. pp. 57-61. Berlin, 1919.

The French " Chevrier " bean is largely grown in the neighbourhood of Paris. The tegument of the seeds, that is, the spermoderm, keeps green even when these are fully ripe ; so do the cotyledons. The shells have a tendency to keep green, fresh and succulent much longer than in other varieties. Crossing Chevrier with types having yellow cotyledons and pigmented spermoderm ♂, we will find on the same mother-plant seeds with yellow cotyledons. This is a plain example of embryoxenia.

The pigmented character of the spermoderm is dominant in F_1, but in F_2 the usual ratio remains, viz. : 3 : 1 (810 : 239 = 3.39 : 1.00).

The positive relation between green spermoderm and the permanence of chlorophyll in the ripe shells is very interesting ; this is observed in F_1 and F_2 when crossing sorts with yellow cotyledons, but there is no relation between the green of the shells and that of the cotyledons. The correlation is therefore quite restricted to organs of permanent natural origin : the spermoderm and pericarp organs originated on the female side. The valves of legumes with yellow cotyledons will keep green and tender till maturity because of embryoxenia.

In F_1 in which the white or pigmented spermoderm dominates over the green, the colour of the pods fades as maturity approaches, but they always contain seeds with yellow and green cotyledons in the ratio 3 : 1. In F_1 only plants with green spermoderm have pods always green, the colour never fading. There may be the combination of valves

that fade, with white spermoderm and green cotyledons ; it is easy to pick out the looked-for combination of green spermoderm and green cotyledons through the deep green colour, while seeds with green cotyledons inside a white spermoderm are light green in colour.

Types which are the result of dissociation, are to be found in F_2 and onwards ; the colours of their valves and spermoderm vary from light to very dark green. This might be explained by the presence of 2 factors, one with a direct and decisive action, and the other acting as an intensifier through a purely catalytic action. The ratio 3 : 1 is but apparent, the real ratio being 12 : 4.

The Chevrier French bean is a first class vegetable. Unfortunately the leaves are damaged by red spider (*Tetranychus telarius*,) while a fungus, *Colletotrichum Lindemuthianum* affects the pod and seeds.

The author is hybridising the Chevrier variety with the varieties Princess, Flageolet, Victoria, Parisien blanc, Wachsdattel, etc., in order to produce resistant and early types with larger seeds keeping at the same time the fine qualities of Chevrier. Types have already been obtained with seeds weighing. 580 gm., the seed of the original Chevrier weighing but 278 gm.

Other crosses were made between Chevrier and Heinrichs Riesenzuckerbrechbohne to create varieties with pods which would remain green until maturity (Chevrier character) that at the same time would not be stringy; very thick and succulent (Heinrich character).

In 1919. good combinations of such characters were obtained in F_2; these types will be propagated in 1920 and then suitability for canning tested.

317 – **Genetic Factors that Determine the Formation of Anthocyanin in Peas.** — Bach, S., in *Zeitschrift für Pflanzenzüchtung*, Vol. VII, No. 1, pp. 61-66. Berlin, June, 1919.

The following gametic formulae concern the colour of the flower of *Pisum* : —

ABAB = homozygotic red
AbAb = homozygotic pink
aBaB = normal white
red × *white* = F heterozygotic red = **AaBB**
pink × *white* = F heterozygotic pink = **ABAb**.

The author carried out a series of investigations for the purpose of ascertaining whether red heterozygotic plants, having **ABaB** structure, can be distinguished from red homozygotic **ABAB** through any appreciable differences in the quality and concentration of anthocyanin. The white varieties " Victoria " ♀ and " Moerheims Riesen " ♀ were crossed with red *Pisum arvense* ♂ and with the pink flower variety " Rote Kronen " ♂. For reference and comparison, besides the 2 above-mentioned homozygotic types the " Niedrige Violette " variety was also taken as a control.

Small pieces of petals were cut weighing 10 mgm. altogether; these were

put in a calibrated tube containing 4cc. of 96 % alcohol, and the tube was closed.

The petals lost their colour after 24 hours, when it may be said that all the anthocyanin had passed into the alcohol. The colour test was easily made with the naked eye by looking at the two alcohol extracts against white paper. The one deeper in colour was diluted with more alcohol till the tint in both was even. The ratio of anthocyanin concentration was established on the proportion of alcohol used for the dilution of the deeper colour.

If extract *A* was deeper in colour than *B* and the alcohol required to bring it down to *B* was 0.8 cc., then the anthocyanin concentration in plant *A* was 3 times that in plant *B*. After even concentration was obtained, the tint underwent further examination as to tone ; for this second colour test the author employed Milton Bradley's colour scale.

Results obtained. — 1) Colour intensity in flowers of heterozygous individuals was equal or higher (1 ½ times) and even lower than the red of homozygous flowers. As far as concentration is concerned, there was therefore no difference between the 2 types; the discrepant analytical data are within the normal limits of the faculty of modification. The colour tone was identical in any case ; the quantity and quality of anthocyanin was consequently absolutely the same in both red homozygous and red heterozygous types.

2) The extract of the pink variety of the " Rote Kronen " was in any case 2 to 8 times less concentrated than the homo-and heterozygous reds.

The 2 red and pink types do not only differ as to colour intensity; there is a difference in the quality of anthocyanin as well: in fact when the 2 solutions are, through dilution, brought to have the same concentration, a considerable difference is noticeable in the colour tone. There are 2 colours instead of one and when examined with the aid of Bradley's scale, we find that red is nearer to Violet Red No. 1 and pink is closer to Violet Red Tint No. 1. The 2 homo- and heterozygous types differ consequently in both colour concentration and pigment.

The factor *B* which is present in both red and white flowers and which can change " pink " to " red ", rather than concurring to intensify the colour produced by factor *A*, is responsible for the formation of a new colouring matter.

318 – **On Some Attempts to Cross-Pollinate Peas and Beans.** — Bach, S., in *Zeitschrift für Pflanzenzüchtung* Vol. VII, No. 1, pp. 73-74. Berlin, June, 1919.

Castration of 10 flower-buds of the pea variety " Victoria " ; 7 of them were artificially fertilised with pollen of *Vicia Faba*, 3 were not treated, all were protected with a parchment paper covers. After 48 hours the stigmata were cut off 3 of the pollinated flowers, fixed in Fleming's solution, and embedded in paraffin. The 7 flowers left were kept for eight days in their paper bags, when they produced pods from 1 to 2 cm. long. and from 0. 4 to 0.6 cm. wide ; the pods were seedless, and soon dried and fell off.

Microscopic examination of the stigma showed that only some of the pollen grains had produced a pollen tube, which was very short, 10 μ at most and was unable to penetrate the tissues of the stigma itself.

We have here the corroboration and cytological explanation of the negative results which attended GARTNER and TSCHERMAK's hybridising attempts. The small seedless pods were of parthenogenetic formation.

The impotence of the pollen of *Vicia Faba* might be explained, the author thinks, by the want of the special chemical stimuli required for the growth of the pollen tube and for enabling it to penetrate.

319 – **On the Heredity of Red and Yellow Colours in *Beta*.** — LINDHARD, E. and IVERSEN KARSTEN, in *Zeitschrift für Pflanzenzüchtung*, Vol. VII, No. 1, pp. 1-18. Berlin, June, 1919.

Plants used in experiments : Eckendorf red beet, Des Barres yellow beet, white sugar beet, *Beta maritima*, and *B. cicla*.

We have in every case a determinant for yellow, the presence of which is indispensable for the manifestation of any colour. R red and Y yellow, together, give red ; Y by itself produces yellow, while R by itself gives no colour.

The gametic formula of a heterozygous plant in relation to Y and R will be R r Y y (F^1) and its descendants would be : —

1	R R Y Y	*red*	constant *red*.
2	R R Y y	*red*	dissociation in 3 *reds* : 1 *white*.
1	R R y y	*white*	constant *white* with *red* determinant.
2	R r Y Y	*red*	dissociation in 3 *reds* : 1 *yellow*.
4	R r Y y	*red*	dissociation in 9 *reds* : 3 *yellows*, 4 *whites*.
2	R r y y	*white*	dissociation in 3 *whites* with factor for the *red* and 1 *white* without such factor.
1	r r Y Y	*yellow*	constant *yellow*.
2	r r Y y	*yellow*	dissociation in 3 *yellows*, 1 *white*.
1	r r y y	*white*	constant *white*.

On the strength of these formulae the observations of the author are easily explained. Nevertheless in certain cases the number of individuals, the colour of which do not correspond with the anticipated proportions, is larger than the mean probable error.

Thus, from a plant with the constitutional formula R r Y Y in F_3, were obtained 120 red individuals and 669 yellow, this being the ratio 2.578 : 1.422, rather than 3.00 : 1.00. The deviation is therefore ± 0. 422 or 11 times greater than the average probable error corresponding to 2000; there is consequently a large surplus of yellows.

In series 9-13 heterozygous hybrids with regard to the 2 determinants R r Y y should produce reds, yellows and whites in the ratio 9 : 3 : 4, that is, the ratio between reds and not reds, should be 9 : 7. In reality the ratio was 8 : 43 : 7.57 with an evident shortage of reds ; thus the deviation was + 0. 57 or 4 times larger than the calculated average probable error

Such occurrences are explained with the coupling of factors, "Factorenkoppelung", thus hybrid R r Y y, instead of producing the 4 ga-

metic forms R y, R Y, r Y, r y in equal numbers, gives through the combination R y and r Y a frequency n times greater than that corresponding to R Y and r y.

Instead of 9 reds : 4 yellows : 4 whites, we should have the ratio: —

$2\ n^2 + 4n + 3$ reds : $n^2 + 2n$ yellows : $n^2 + 2n + 1$ white.

Considering the cases as a whole we find n between 1.65 and 1.75. There is therefore coupling of R with y and r with Y, but the coupling is not perfect as it requires the combination of Y R and r y according to a percentage of "crossing over" equal to 36-38 %.

CEREAL AND PULSE CROPS

320 – **Effect of Temperature on the Quality of Sweet Maize.** — STEVENS, N. E. and HIGGINS, C. H., in *Journal of Agricultural Research*, Vol. XVII, No. 6, pp. 275-284 + 4 figs. Washington D. C., Sept., 1919.

The temperature at which sweet maize remains exposed after harvest has considerable influence on its quality. It is generally admitted that sweet maize canned near the northern limit of its cultivation is sweeter than that which is canned farther south. From the investigations of STRAUGHEN and CHURCH it appears that the sugar content of the same variety of maize when harvested is approximately the same in Florida, South Carolina, New Jersey and Connecticut. The factor which eventually has an influence on the concentration of sugar would be the temperature during the period of preparation of the produce for commerce.

The authors, working on these, lines have been able to determine that;— (1) Maize deteriorates rapidly after it is picked (loss of sugar) and that; (2) the rate of deterioration is greater when the temperature is higher.

The variety "Stowell's Evergreen" (Maryland) when freshly pulled contained from 4.59 to 4.74 % of sugar. After 24 hours at room temperature, one-third of the sugar had disappeared and the loss continued until the sugar content fell to 1.80 %. At a temperature of 30° C. more than 40 % of the sugar was lost in 24 hours.

To show that the deterioration of the quality of the grain is in direct relation with the temperature the authors made the following experiments: —

Some ears of freshly picked maize (variety "Early Bantam") were split lengthwise; one half was left in room temperature (about 20° C.) and the other half was placed in a refrigerator and kept at a temperature of 10° C.

An analysis of the percentage of sugar made after 26 to 30 hours showed that the percentage was much higher in the halves kept in the refrigerator.

Given the existence of a relation between the temperature and the sugar content of maize, it is very easy to explain why sweet maize canned in relatively cold regions is superior in quality to that canned in relatively hot regions.

In Maryland sweet maize is canned in August at an average temperature of 23.67° C., while in Maine canning is done in September at an average temperature of 15.28° C. The difference between these temperatures explains the difference in the quality of the produce generally noted.

Percentage of sugar in the respective halves of each ear.

Ear N°	Percentage of sugar in the half kept at 20° C.	Percentage of sugar in the half kept at 10° C.
	%	%
11	2.43	4.06
12	1.90	3.14
13	2.28	5.54
14	1.90	3.71
16	1.86	3.18
17	1.78	4.21
Average	2.02	3.97

FIBRE CROPS

321 - **Kapok in French West Africa.** — CHARTIER, J., in *Bulletin économique de l'Indochine*, Year XXI, New Series, No. 138, pp. 784-786. Hanoï-Haïphong Sept.-Oct., 1919.

During the war kapok was much in demand by the French Admiralty and its use since has become more general. Kapok is common all through tropical Africa, but it is only during the last few years that quite a trade started in a small number of colonies. All the kapok imported in Europe is for the greater part supplied by British India and the Dutch East-Indies. Indo-China (Cambodia and Tonkin) produces it, but it is all used locally ; there is kapok also in Mexico and Brazil. Among the late German colonies attention was given to kapok in German East Africa ; Togo also exported a few tons in 1912 and 1913.

From the upper Sénégal-Niger 962 kg. were exported in 1911, 8 tons in 1912 and 28 tons in 1913.

Kapok has been exported from the Ivory Coast since 1913 and though figures are so very small, they point to the beginning of a trade that has great possibilities What has been attempted in these 2 colonies could be tried in all French West Africa where kapok trees are most common ; they grow wild from the Gulf of Guinea to the limit of the Sahara or mid-Sahara zone. The 2 principal sorts are the bombax and the ceïbas, both gigantic trees Bombax yields a clear snowy white wad; ceibas produces greyish or light red material of lesser value than the former, but being very plentiful this crop is not to be overlooked.

In 1913 the Colonial government forbade the cutting of kapok trees in order to preserve a wealth of which native inhabitants were unaware.

The author describes methods for gathering kapok Bamboo rods by carrying a wooden hook at the end to gather the hanging crop instead of being satisfied solely with the picking of the over-ripe fruit fallen to the ground ; pickers should be supplied with bags to avoid packing in leaves. For want of a small threshing machine the old Malay system might be used consisting in thrashing and shaking kapok on a bamboo flooring. The bamboo canes are not quite closely laid, so they allow kapok seeds etc. to fall through the space left between them. A great future awaits the industry in French West Africa if, as old plantations are exhausted, new planting is carried on without neglecting

plant selection. Bombax propagated by cuttings produces kapok after 5-6 years, raised from seeds after 8-10 years.

22 – **The Fan-Palm of Southern Annam and its Fibre.** — I. Petite préface de CHEVALIER, AUG. (Directeur de l'Institut Scientifique de Saïgon). — II. BUSSY, P., in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 12, pp. 377-380. Saïgon, Dec., 1919.

I. — In Annam and Cochin-China there is a palm with flabellate leaves, which fills a great place in the natives' domestic economy. The native name of these leaves is " La-buôn " and they are used for thatching roofs, for making various kinds of baskets and a sort of sunshade. Sails are also made out of the younger leaves; these are divided into strips, which are sewn together afterwards; the sampans sailing along the coast of Annam are fitted with these sails. Older leaves, first made into strips, then sewn together and bleached are used for making partitions, which separate the rooms in an Annamite house.

LOUREIRO knew the native " La-buôn " industry, as well as the native name of the leaves; he had heard of this palm living in the forests of the Moïs country, but he had never seen it. He described it and called it *Pandanus laevis*, wrongly classifying this palm as *Pandanus* and identifying it with *Pandanus moschatus* syn. *laevis* by RUMPHIUS.

" La-buôn " really is a palm of the genus *Corypha* and, if its old specific name were traced, we should have the following synonymy: — *Corypha laevis* (Lour.) A. Chev. (*Catal. Jard. bot. Saïgon*, May, 1919, p. 56) = *Pandanus laevis* Lour. = *Corypha Lecomtei* Beccari.

Corypha laevis is common in the forests of Southern Annam and north-western part of Cambodia; it is the " Tréang " of the Cambodian natives. Unknown in the forests of Northern Annam and Tonkin., there its place is taken by a *Livistona*, a palm whuch is grown on a large scale, especially in central Tonkin.

The following account concerns only the fibre of *Corypha laevis* of Southern Annam and North-western Cambodia; the information was supplied to the " *Institut scientifique* " by the Annam Forestry Department.

II. — The author tried experiments aiming at utilising " La-buôn" fibre as a textile. He obtained it from the leaf-stalks and blades of 2 lots: one was made of full grown leaves, already partly dry, the other lot was made of leaves that were still closed.

Throughout the leaf, the fibres are grouped in bundles and bound by different pectic and nitrogenous substances, vasculose, cutose, etc. which must be removed by suitable solvents, which should not appreciably alter the colour and resistance strength of the fibre.

The author describes the different processes, by which he extracted fibre from the petioles: —

1) Mechanical treatment by breaking the leaf-stalks with a wooden mallet; 2) treatment with steam; 3) chemical treatment. The best chemical for the purpose was sodium carbonate 10 % strong, cold, or heated under 6 ½ lb. pressure.

From the trials made the author arrived at these conclusions: — bundles of fibre of great length may be mechanically prepared by moderately beating leaf-stalks with a wooden mallet and so avoiding much waste. However the fibre that falls out during this treatment may be worked into fairly strong ropes. Of all processes steam treatment under pressure and the prolongued steeping in a weak solution of sodium carbonate are those that least affect the resistance of the fibre.

Leaf-stalks and leaves, whether full grown or still closed, might be utilised for the extraction of long staple and, if the latest appliances were employed, this might yield some of the best textile materials.

323 – **Investigation of "Marine Fibre", the Fibre of *Posidonia australis*.** – READ, J. and SMITH, H. G., in the *Commonwealth of Australia, Institute of Science and Industry. Bulletin* No. 14, pp. 40, bibl. of 66 works, plates 20. Melbourne, 1919.

The fibre has its origin in the leaves and stems of the monocotyledonous plant, *Posidonia australis* (N. O. Naiadaceae), which so far has been recorded from the foreshores of Western Australia, South Australia and New South Wales and from Tasmania; but it probably extends around the whole continent. It is a submerged marine flowering plant.

The fibre is pale brown in colour, being of a lighter shade and coarser than coconut fibre ("coir" taken from the outer coating of the coconut), to which it bears a general resemblance. The fibre bundles are short (5 to 20 cm., generally 10 to 17 cm.); with an average tensile strength of 20.15 kg. per sq. mm., and an elongation of 5.29 % (variable). They are of a very brittle nature. The length of the filaments is from 5 to 1 mm.

The chemical structure of marine fibre corresponds with that of lignocellulose, intermediate in character between jute and wood ligno-cellulose, but it is characterised by its marked resistance to dilute alkalis, and to cellulose solvents and by its unusual affinity for dyes, especially basic colouring matters.

The *Posidonia australis* cellulose is obtained in a 55 % yield when the fibre is submitted to the chlorine sulphite process. It resembles esparto and straw cellulose both in its high furfural value and in its length.

The raw material yields 7.5 % furfural, and 9.2 %. crude cellulose But the cellulose of *Posidonia* yields no colour with aromatic amines compared with esparto cellulose, etc. The treatment of the cellulose with a 17.5 % solution of caustic alkali gave 79.2 % of cellulose, which gave in its turn 2.9 % furfural.

In this respect is it is very similar to esparto cellulose.

The workable area of the South Australian *Posidonia* deposits has been estimated at 4600000 tons of fibre, which, washed and purified with acids. could be landed at a European port at £19 per ton. The shortness, coarseness, and lack of flexibility and cohesion as well as the structural characteristics of the filament, are all opposed to its employment in the fabrication of fine textiles.

In the fabrication of lower grade fabrics, marine fibre can be mixed with wool, and is advantageous owing to its low heat conducti-

vity. For coarse textiles, marine fibre is inferior to jute with regard to mechanical properties, but owing to its resistance to the action of chemical and bacterial agents, it would be of especial use in the manufacture of coarse fabrics, which might be required to withstand continued exposure to weather.

Although the structural attributes of the filaments are unfavourable for textile purposes, a marked degree of success has been obtained by means of preparatory treatment with dilute acids. The flexibility, and also to some extent the tensile strength show an increase if the fibre is treated for several hours with a solution of 2 % nitric acid; other acids have a similar effect although less marked. After this treatment, the loss in carding is less owing the increase of elasticity.

As a source of explosives, marine fibre has given negative results. When a method for the separation of filaments has been found, the best use for *Posidonia* will be in paper making. The close resemblence between this cellulose and that of esparto, has led to the belief that paper thus made could be used for printing and for ordinary writing paper.

PLANTS YIELDING OILS, DYES, TANNINS, ETC.

324 – **Cultivation of Plants with Oleaginous Seeds in Holland.** — *Tijdschrift voor Economische Geographie*, Year X, No. 4, pp. 148-154. The Hague, 1919.

Even in 1669 there was a regular market for linseed oil at Amsterdam. In Holland, the cultivation of flax and other plants with oleaginous seeds had undergone, from 1851 to 1914, the changes indicated in the following table :

Area of crops yielding oil in Holland, from 1851 *to* 1914.

Plants	1851-1860	1861-1870	1871-1880	1881-1890	1891-1900	1901-1910	1913	1914
	hectares	hectares	hectares	hectares	hectares	hectares	hectares	hectares
Rape	28 658	23 117	12 690	7 635	4 701	3 047	1 193	1 654
Sunflower . . .	—	—	1 511	866	467	419	783	720
Flax	14 990	21 293	18 530	14 665	11 973	14 027	14 650	7 723
Hemp	1 556	1 460	1 412	389	173	67	30	30
Caraway . . .	—	—	—	2 301	3 380	5 394	5 527	5 285

This table shows that there was, generally, a decrease in these crops, with the exception of caraway ; but the latter is used as a condiment, and furnishes an essential oil.

This decrease in crops is due to the development of imports of exotic oleaginous raw material. In fact while there were, in 1878, only 5 steam oil-factories, there are now 50 steam factories and a total of 135.

RUBBER, GUM AND RESIN PLANTS

325 – **Precautions during Smoke Treatment of Rubber.** — VERNET, G. (Directeur du Laboratoire d'analyses de l'Institut Scientifique de l'Indochine), in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 12, pp. 362-364. Saïgon, Dec., 1919.

Smoke treatment is excellent for the preparation of Hevea rubber (1) but the manner in which it is applied is fraught with serious danger of fire.

(1) The advantage of smoke treatment of rubber was much emphasised by M. FELIX RIPEAU a work published in 1914 bearing the title *Caoutchoucs* (*Hevea brasiliensis*) *ama-*

The following information aims at teaching planters how to avoid mishaps that might degenerate into disasters.

The heat developed by rubber on fire is such, that all efforts to extinguish it are useless and that the only thing that can be done is to isolate the outbreak.

The contrivances used at present for smoking rubber are more or less conceived in the same manner : — a fire-place outside with pipes leading the smoke to the room where the rubber sheets hang for treatment. If the size of the fire-place is adequate, it is easy to make the quantity of smoke required, by regulating the access of air and so engender incomplete combustion. Smoke is accompanied by soot and tar, which carried by a draught of hot gases, settle or are condensed inside the chimney and inside the pipes.

---

zoniens et asiatiques, Étude comparative. Le traitment du latex. EMILE LAROSE édit., 11 rue Victor-Cousin, Paris.

In this work the author compares rubber grown in the Far East with that produced on the Amazon ; he indicates the reasons of the lower quality of the former and gives valuable information on improved systems of rubber growing and better handling of the latex.

It is to be noted first that the Heveas cultivated in the Far East are not the same variety or sub-species as those on the Upper Amazon famous for their product, Para-rubber.

Rubber trees of the Upper Amazon are the *Hevea brasiliensis* " preta ,, black, which yields the true black rubber.

The Heveas in the Far East came from the Lower Amazon, which even in their ordinary habitat yield a weaker latex after coagulation. The latex on the upper reaches of the Amazon yields 50-52 % dry rubber, but on the plantations it rarely is more than 25 %, a 30 days' average being 20 %.

On the lower course of the Amazon there are different varieties, which rubber planters call after some of the characters of the latex; thus *Seringa branca* is the Hevea producing white latex, *Seringa fraca* the one with weak latex, *Seringa morada* yielding purple latex, *Seringa queimada* that with dark brown latex. The latex of all these varieties is more fluid, than that of the black Hevea.

According to the author the Heveas of plantations in the Far East are seedlings of the *Hevea morada* introduced in 1874, which is the best of the 4 above-mentioned varieties. It is not improbable that from seedlings of two imported varieties a third originated at some acclimatisation station in a British colony, c. e. *Hevea confusa*, which became afterwards the variety predominant on Asiatic plantations.

The author believes that true black Hevea cannot be planted anywhere in Asiatic countries ; French Indo-China suits Hevea best, provided that it be planted in red soils of inland districts.

In order to obtain good rubber in the Far East, whatever the variety may be, tapping should never begin before the tree is 8 or 10 years old, not at 4 as it is now done. The tree should be allowed to rest : — 1) From the autumn till when the leaves are fully on again; 2) during the height of the rainy season, because latex then is too thin. (On the subject of the age at which a tree may be tapped and on the extent of tapping operations, *See* précis of Girard's work in this *R.* January, 1920, No. 50). Further precautions are necessary see as follows : —

1) to adopt a method of tapping whereby the greater portion of the suitable bark may be utilised ;

2) to shorten the run of the latex to the cup ;

3) to avoid water getting into the latex by seeing to the basins used for latex collecting and by tracing the track for the latex flow not with water but with latex itself ;

It will be impossible for these to catch fire if the quantity of fuel to bank up in the fire-place is larger than that burnt with the draught raised. If on the contrary there is not enough fuel banked, or the draught is much too strong, the air rushes up the chimney and smoke pipes and carries with it the flames which ignite soot and tar. A fire thus starts like an ordinary chimney fire, the consequences of which may not be serious, if limited to the " stickage " of the nearest rubber sheets, but may have the most serious consequences, for the whole crop may be destroyed and the building with it.

Against such untoward occurrences a number of precautions may be taken:

(1) Sweep the chimney and scrape all smoke-carrying pipes, which

---

4) to protect all vessels from air and dust;
5) latex handling should be done under conditions of utmost cleanliness;
6) to do away with acids for the coagulation of rubber;
7) not to employ rubber sheeting appliances before rubber has acquired body;
8) to dry rubber rapidly, by sun drying or drying in vacuum.

The author sees in the smoke treatment a good substitute for acids to assist coagulation. He obtained good results with carbon dioxide and creosote; creosote, being heavier, collects at the bottom and acts on the latex through its emanations; rubber is thus sterilised without any foreign substance remaining caught in it.

Smoke treatment: 1) does not hasten coagulation, but allows it to take place naturally, which is of the utmost importance; 2) sterilises rubber without leaving traces of foreign substances; 3) makes possible sun-drying, drying in vacuum or in special drying rooms. (According to the author, when acids are used as coagulants, it takes 2 or 3 months properly to effect drying in suitable places where sun-light is regulated; on the contrary 4 or 5 days of sun drying are sufficient in the case of rubber coagulated by the agency of smoke).

The system adopted by the "*seringueros*,, of the upper affluents of the Amazon, apart from being lengthy, cannot be applied to the latex of Hevea plantations, because this is much thinner.

The author conceived an excellent plan for the latex of *Hevea preta*. A drum arrangement takes the place of the other contrivance used by the *seringueros* for making the rubber ball, which is so hard and difficult to start. The drum is first smoked, then its cylindrical surface receives from 15 to 20 coats of latex; after smoke treatment rubber sheets are obtained in this way from about 1/6 to 1/4 inch thick according to market requirements. The drum after every 5 or 6 daubs should be rolled over a flat board in order to press the rubber on to the cylindrical surface; it will take rubber 10 minutes to harden and cool, after which the rubber sheet may be detached.

This method does not suit the thin latex of Heveas in the Far East. For this the author invented a special smoke treatment, which can be relied upon to give very good results. He gives a detailed description of the system and of the plant required. Briefly, these are the main points of the system:— 1) a layer of latex 4/5 inch at most, is kept exposed to smoke in a closed room; the temperature of the room is lowered till the formation of a coagulum; this is washed, partially dried, drained under slight pressure and finally thoroughly dried; 2) the plant comprises a board on which can be placed many small basins all containing the aforesaid latex layer of 4/5 inch; the board is placed in a cupboard of metal sheetings or in a room that can be well closed. Smoke from a stove is made to circulate round the room, round and over the basins containing the latex. Through special appliances smoke temperature can be regulated at will. (*Ed.*)

should consequently be so arranged as to make their frequent inspection easy.

(2) Unless great negligence be shown, it is easy to avoid the consequence of not having enough fuel banked up on the grate. For this it will be sufficient to adopt that system of banking the fuel in a box placed over the fire and in communication with the grate; from this box fuel automatically falls on the grate in the same proportion to that which is burnt. Fuel consumption is regulated by the amount of air admitted ; it is necessary to see that the fuel box never runs empty and that the grate is kept clean.

(3) Concerning fire prevention it is never superfluous to take all possible precautions even when these might look like a duplication of work.

If we trace the outbreak to the pipes, the simplest way to stop the fire is to stop the air, which is done by closing the 3 ends of the system. It happens, however, that when fire breaks out, nobody is about the place or the fire is noticed when it is too late for any action to be of real help.

Fire alarm devices are therefore necessary and the author describes one that could be easily made on the plantation. It is sufficient to place at intervals inside the pipes a sort of vertical trap very similar to a tiger trap and at the mouth of the stove or fire-place, a kind of mouse-trap as placed at the delivery end of the smoke driving pipes. These are all kept in position by a wire which runs through the pipes and over a pulley at the end. The wire is made of a metal with low melting point ; if fire starts up in the chimney or in any of the pipes, the temperature rises, the wire melts, the traps drop and close the system ; air being thus shut off, the fire stops.

It would be useful to put up several such arrangements through the whole system and, whatever the device adopted may be, care should be taken to keep it in working order by preventing an accumulation of soot and tar on the gear. The safety wires commanding the traps should be of tin, lead or zinc the melting points of which are 439°, 635°, and 743° F. respectively.

(4) At any time, through unsatisfactory working, the device might not prevent the leaping flames from reaching the delivery end of the pipes inside the drying room ; against such possibility it would be wise not to hang the rubber sheets too close to them and so avoid " stickage ".

SUGAR CROP

326 – **The " Uba " Variety of Sugar Cane in British South Africa.** — *Tropical Life*, Vol. XV No. 10, pp 154-155. London, Oct., 1919.

In 1897, Zululand was annexed by England and became part of Natal its area is about 10 500 sq. miles and its population, according to the Census of 1904, consisted of 1693 Europeans, 203 373 natives and 120 Indians After the publication of the Zululand Commission's report in 1905, agricultural settlement made rapid progress; for this the sugar industry is solely responsible and the " Uba " variety of sugar-cane has largely contributed to the progress made.

Although the sugar-cane is a tropical plant requiring great heat and an abundant rainfall, it can be successfully grown in a sub-tropical climate, as is proved by the plantations in the coastal belt of Natal, a region extending from Port Shepstone (on the south coast) to beyond the Umfolosi River (on the north coast), and measuring about 260 miles in length.

The average mean temperature of this sugar-cane region in Natal is 77°F. and the superior results obtained in Zululand are attributable to the higher mean temperature prevailing in that northern area, where the period necessary for the maturing of the cane is, consequently, shorter.

As sugar-cane does not mature in one year and has to face extremes of climate, severe losses are common; thus, the "Uba" variety of cane is extremely interesting because of its great resistance to local adverse conditions. The average annual rainfall is a little under 40 inches, but this limited rainfall is in some measure compensated for, by heavy rainfall precisely at the period of vigorous growth of the cane, by a comparatively humid climate and by judicious manuring.

It is said locally that the name "Uba" or "Yuba" is derived from the only letters legible on the label attached to this variety when first brought into the colony. The origin of this variety is uncertain: some say that it originated in Brazil, others that it originated in India and was introduced into Brazil.

Mr Pearson gives the following analysis of the juice of the "Uba" sugar-cane:—

	Average	Maximum
Total solids	20.32 %	22.79 %
Sucrose	18.61 %	20.79 %
Purity	91.60	91.20

Though there is a large proportion of fibre in the cane, this indicates no inferiority in the juice; in fact the quality of the juice is not surpassed by any other variety, as is shown by the results of analyses made of 33 other varieties (chiefly Hawaiian and Demeraran).

In conclusion the utility of nitrogenous fertilisers in conjunction with phosphatic and potassic fertilisers in the Hawaiian islands is referred to, and the method of cultivation practiced in those islands is described (1).

(1) The work by M. Léon Colson entitled *Culture et Industrie de la canne à sucre aux îles Hawaï et à la Réunion*, 1 Vol., 431 p., 1905, Challamel Édit., 17 rue Jacob, Paris, may here be referred to: the question of fertilisers for sugar-cane cultivation in the Hawaïan islands is dealt with on pp. 32-34. (*Ed.*)

327 - **Experiments Made in India Regarding: I. The Method of Planting Sugar-cane Setts; III. The Effect on the Yield of Various Plants of the Position of the Seeds in the Soil at the Time of Sowing.** — KULKARNI, M. L. (Acting Deputy Director of Agriculture, Southern Division, Bombay Presidency), in *The Agricultural Journal of India*, Vol. XIV, Part 5, pp. 791-796, 2 fig. + 5 pl. Calcutta and London, Oct., 1919.

I. — Results of experiments comparing the method of planting sugar-cane setts of one eye-bud placed upwards with other improved methods, especially with the method of setts of 3 eye-buds pointed sideways.

Owing to special conditions of soil and water the Brix reading of the juice scarcely exceeded 14 % in the different methods of cultivation. Hence the Table given below (which compared the results given respectively by: — (*A*) Setts of one eye-bud pointed upwards; (*B*) setts of three eye-buds pointed sideways) indicates only the yield in cane and not the yield of "gur" (crude sugar).

Results of comparative experiments of plantation.

Method of planting	Number of eyes planted	No. of plants germinated after 20 days of planting	Percentage of germination	No. of plants finally Kept (mother and tiller plants)	Number of canes harvested	Weight of canes harvested	Average weight of one cane
						lb.	lb.
I. — Plot of 1 "guntha" ($^1/_{40}$th of an acre):							
A) Single eye-bud, point upwards	901	833	82	1 079	843	4325	—
B) Three eye-buds, points sideways	1 002	511	50	889	782	3366	—
II. — Plot of 30 "gunthas" ($^3/_4$ *of an acre*)							
A) Single eye-bud, point upwards	27 030	24 990	82	32 370	25 290	129750	5.1
B) Three eye-buds, points sidewais	30 060	15 330	50	26 670	23 460	100980	4.3

The Brix reading being only 14.2 % in both methods of planting, the yield in "gur" obtained for 30 *gunthas* was: —

(*A*) Single eye-bud, point upwards . . . . . 12 570 lb.
(*B*) Three eye-buds, points sideways . . . . . 9 660 »

If the Brix reading had been 18 to 19 %, as is usually the case for sugar-cane, the yield in "jur" would have been: —

(*A*) Single eye-bud, point upwards. . . . . 16 350 lbs
(*B*) Three eye-buds, points sideways. . . . . 12 725 »

These figures show that the yield of cane was about 25 % higher with method (A) than with method (B). Further experiments on a larger scale are being carried out on the Canal Farm at Gokak.

There are, however, certain disadvantages in the method of planting single eye-buds, point upwards. The setts being too small and exposed on both sides close to the bud, the plants developed from them, though they take more quickly than those developed from setts with 3 eye-buds, points sideways, look somewhat unhealthy during the first month until a small dose of ammonium sulphate is given as a top-dressing ; but after that top-dressing the plants (A) grow as luxuriantly as plants (B).

The following year a fresh experiment was made: — Setts with 3 eye-buds were taken and the middle eye-bud was removed ; the sett was then planted with the two remaining eye-buds upwards. It is expected in this way to obtain a better yield than with the single eye-bud point upwards method of the previous year, owing to the elimination of the defects of the single eye-bud method while retaining the advantage of position of the eye-buds point upwards.

II. In view of these results, the author investigated the effect which the position of the seed in the soil at the time of sowing might have on the yield of various plants.

Experiments with maize, leguminous plants and cotton showed that when the seed is planted with the point downwards or sideways, the resulting plants are better than when the seed is planted point upwards.

The position of the seed in the soil at the time of sowing is one of the numerous causes of the unevenness in plants and crops, and even of the non-germination of good seed. But in practice it is only possible to plant the seeds in the proper position when planting is done by hand.

328 – **Prevention of Soil Erosion on Tea Plantations in Southern India.** — ANSTEAD, R. D. in *The Agricultural Journal of India*, Vol. XIV, Part 5, pp. 787-790. Calcutta and London, Oct., 1919.

STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS

At the meeting of the Board of Agriculture in India, held at Pusa in 1916, the subject of soil erosion was discussed and it was resolved to bring to the notice of planters the fact that the serious losses hitherto due to this erosion are to a large extent preventable.

Dr. HOPE, of the Indian Tea Association, has published an interesting account of the terrace methods adopted in Java, to prevent loss of valuable top soil in the tea districts. This te racing, however, was done before the plantations were made. The problem presented on many tea estates in the South of India is, on the other hand, to stop soil erosion on old established plantations, and a good deal of work has been done in several districts during the last few years with the object of solving this problem in a practical and economic manner. Two methods have been adopted with success. The first is a modification of the terracing done in Java. At the time of pruning, trenches are opened along the contours of the slopes at intervals of 4 or 5 rows of tea bushes. These trenches are from 18 to 24 inches deep and are filled with the tea prunings the upper layer of prunings being packed so that the butts project 6 to 8 inches from the ground level, when the trench is filled, and thus form a low fence. The soil in the intervening rows of tea bushes is then forked and manured, if

necessary ; and in some cases a green manure crop is sown on it. The low fence of buried prunings serves to catch any soil washed down. Unfortunately, the tea bushes have generally been planted not along the contours but along the line of steepest slope. It is, however, possible to work along the contours and gradually arrive at the formation of terraces where the prunings have been buried. At the next pruning season the terraces are improved and new ones made in the same way. This method has been found to work excellently on moderately steep slopes where it is already much used.

The second method used is to abandon forking and clean weeding (1) on steep slopes and to keep the soil covered with suitable weeds. This method, of course, meets with opposition from planters of the clean-weeding school, but in Southern India the fetish of clean weeding is becoming obsolete. The proposed method has the defect, in dry seasons, of depriving the tea bushes of part of the moisture of the soil and the tea may suffer, but this defect cannot compare with the harm done by the erosion of bare soil. The choice of plants to be used for covering the soil is very important. Ideal plants are leguminosae, as they will fix nitrogen and neither climb into the tea bushes, nor form too thick a mat on the ground, and do not grow more than a few inches high. Such a plant is difficult to find, and the plant which seems to come nearest to the ideal is *Cassia mimosoides* L. a leguminous plant which, at altitudes of 4000 feet and over, keeps low and spreading ; it allows the rain and sun to reach the soil while protecting it from erosion ; it is easily established and seeds freely.

Another leguminous weed experimented with is *Parochetus communis* Hamil., a plant with a clover-like habit, but it is not easy to establish over large areas for its life is not long and it dies down to the creeping rhizome in the hot weather.

When a suitable leguminous plant cannot be found other weeds can be used, among which may be mentioned *Oxalis corniculata* L., *Cotula australis* Hork., *Cardamine hirsuta* L., *Galinsoga parviflora* Cav., and *Laurembergia* (*Serpicula*) *hirsuta* W. and A.

329 – **Possibilities of Tobacco Cultivation in British India.** — *The Wealth of India* Vol. VIII, No. 9, p. 422. Madras, Sept., 1919.

Dealing with the future possibilities of tobacco cultivation in India, specially as regards the raising of new varieties, the Director of Agriculture at Hyderabad states that India is situated more favourably than European States where foreign varieties of tobacco have been acclimatised. In Europe the climate is such as not to allow of the full attainment of the aroma which the introduced varieties possess in their country of origin but Cuban tobacco has been successfully grown in Austria with remarkably good aroma, and there is no reason why foreign tobacco should not be grown and retain its original qualities (if manuring and curing are properly

(1) Regarding, clean weeding see *R.*, Febr. 1919, No. 205, III, where this method is described with reference to Hevea plantations in Indo-China. (*Ed.*)

attended to) in such a vast country as India where it should not be difficult to find a soil and climate suitable for its acclimatising. As in the case of peanuts and other crops, India should produce excellent tobacco and might become the chief tobacco supplying country in the world.

330 – **Experiments in Tobacco Growing in Cambodia** (1). — DELOCHE DE CAMPOCASSO, (Chef p. i. des Services agricoles et commerciaux an Cambodge) and MERCKEL (Chef de la Station séricicole, d'élevage et d'hydraulique agricole du Petit Takéo) in *Bulletin économique de l'Indochine*, Year XV, New Series, No. 238, pp. 781-782. Hanoï-Haïphong, Sept.-Oct., 1919.

The experiments were carried out at the agricultural station of Petit Takéo, near Phnom-penh, with varieties supplied by the Tonkin Tobacco Factory and with a native variety.

These trials were made in a year of extraordinary drought and in strong clay soil; plants therefore suffered from climatic adversity and, notwithstanding that, however, vegetation was generally good. The varieties were 1) Comstock, 2) Maryland, 3) Hungary, and 4) Khmer (Cambodia variety).

1) *Comstock.* — The best of the 4 varieties tried from the point of view of growth, size of leaves, aroma and combustibility. The aroma is not too strong and the colour of the leaves is much darker than that of the other three. It was the least affected by insect pests. The crop of leaves, after curing, was 670 kg. per hectare.

2) *Maryland.* — The least satisfactory growth and appearance of leaves, which are much smaller, wrinkled, and subject to attacks from insects; crop 326 kg. per hectare.

3) *Hungary.* — Good variety, satisfactory growth, leaves lighter in colour than those already mentioned; little attacked by insects. Very much like the variety Khmer in appearance, so much so that even experts may easily take one for the other. Crop 854 kg. per hectare.

As cigarette tobacco it burns well, leaving a white ash; the smoke is not acrid, the aroma is light and agreeable.

4) *Khmer.* — This is the common variety of the country, very good from the point of view of vegetation. Beautiful leaves, crop 1000 kg. per hectare. It is the largest yielder. Tolerably good as cigarette tobacco, the aroma is rather peculiar and many do not like it.

The author remarks that the variety Hungary has all the hardiness of Cambodian Khmer and has, moreover, aroma, combustibility and sweetness; it would be worth while to continue the experiments and for the present, limit the trial to this variety.

331 – **Cinchona and Rainfall in Indo-China.** — VERNET, G., in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 12, p. 380. Saïgon, Dec. 1919.

The *Bulletin pluviométrique* for the year 1918, published by M. G. LE CADET, Director of the Central Observatory of Indo-China, contains

(1) See *R.*, Jan., 1919, No. 61. *Tobacco Growing in Indo-China.* (*Ed.*)

valuable information regarding the agricultural possibilities of the colony, as the rainfall chart inserted at the end of the pamphet gives a general idea of the distribution of rainfall throughout Indo-China.

The comparison of this document with the report of M. CAPUS, entitled " The Possibilities of the Cultivation of Cinchona in Indo-China ", reproduced in this *Review* (1), will give an idea, based on actual observation, of the regions which are worth studying, especially as regards cultivation of cinchona. It is thus noted that the portions of the area where rainfall exceeds the annual 2500 mm. are very extensive in all the mountainous regions, and those which exceed 3000 mm. are not rare in Indo-China, that is to say in regions whose altitude does not correspond to too marked a decrease in temperature.

The cultivation of cinchona need not be limited to the highest regions of the Indo-Chinese mountains, for the average latitude of the colony is very different to that of India or Java (2). The high valleys and plateaux whose altitude does not exceed 1000 m. ought to be specially investigated with this object.

ARBORICULTURE

332 - **Progression of Ripening of " Knife " Pears.** — RIVIÈRE, G. and BAILHACHE, G., in *Journal de la Société Nationale d'Horticulture de France*, 4th Series, Vol. XX, pp. 306-307. Paris, Dec. 1919.

Experiments by the authors on pears of the varieties Beurré Hardy, Duchesse d'Angoulème, and Doyenné du Comice, which have enabled them to determine that ripening of " knife " pears shows itself first in the tissues near the peduncle, and that it progresses gradually up to the eye, but with greater or less rapidity according to the variety.

The analytical results obtained are shown in the following table: —

Progression of ripening of pears.

	Percentages of sugar in the pulp		
	Beurré Hardy	Duchesse d'Angoulème *	Doyenné du Comice
1) Part near the peduncle . . .	8.91 %	12.31 %	10.78 %
2) Central part	7.98	12.10	10.72
3) Part near the eye	7.90	12.12	10.62

* At the time of the analyses the Duchesse was the ripest of the pears.

VITICULTURE

333 - **Viticulture in the State of Victoria, Australia.** — *Queensland Agricultural Journal*, Vol. XII, No. 4, pp. 186-187 and No. 5, pp. 246-247. Brisbane, Oct. and Nov., 1919.

The United Kingdom imports large quantities of fresh grapes from Spain. The export of fresh grapes from Spain starts every year in July and lasts till December. The largest consignments are made in the winter months; the quantity shipped to the British Isles and other European

(1) See *R.*, Jan., 1920, No. 55. (*Ed.*)

(2) For " The Cultivation of Cinchona in Java " see original article by Dr. J. VAN BREDA DE HAAN in *R.*, Nov., 1915. (*Ed.*).

countries and to North America is about 57 000 tons. From this figure may be gathered the importance commercially. The variety is the " Ohanez ", better known by British merchants by the name of Almería, because Almería is the port of shipment.

Grape-growing on a large scale has good prospects in Australia. There is, in fact, a large local demand for fresh grapes and the vine is also cultivated for raisins and wine ; but the best possibilities in front of Australian viticulture lie in the export trade. In fact, from its geographical position Australia can supply the United Kingdom when there are no other grapes on the market ; Australia would do well by shipping grapes, when none are being sent from Spain, and this would be just about the end of winter.

The " Ohanez " variety is most suited to Australia, particularly to the northern districts of Victoria, where the atmosphere is drier than in the Spanish province of Almería ; there the character of this grape would show to advantage. It is a choice variety, heavy bearer, tough skinned, very much appreciated on local and foreign markets. These grapes are of excellent quality and are the best for export ; they travel well and arrive in quite good condition on the overseas markets.

A trial shipment proved a most successful venture ; Ohanez from Victoria fetched in England a higher price in summer than did Spanish grapes in winter. The net return per acre was very handsome.

To grow " Ohanez " successfully, fairly good soil is required and water should be available for irrigation purposes. Easy access to the railway is also needed.

An important company, the " Australian Farms Ltd. " (King St., Melbourne), is doing much for the development of the Victorian grape industry. This company has secured some very good land for the purpose on the shores of Lake Kangaroo. It can be irrigated and is near a railway station. The company offers good terms to intending vine growers and assistance in various ways.

LIVE STOCK AND BREEDING

334 - **The " Lucacha " *(Latrodectus mactans)*, a Small Peruvian Spider whose Bite is Poisonous to Man and Animals.** — ESCAMELS, ED., in *Bulletin de la Société de Pathologie exotique*, Year XII, No. 9, pp. 702-720, 1 fig. Paris, Nov. 12, 1919. HYGIENE

Study made in Peru by the author, on the " lucacha ", a small black spider with red spots, identified as *Latrodectus mactans* Fabr., which adapts itself to all climates in the world, tropical as well as the very cold climates of the high plateaux of the Peruvian Sierra. This spider is poisonous but, according to the author, the effects of its bite have been attributed to the bite of other animals (a scorpion, *Brachytosternus ehrenbergi* ; an inoffensive lizard, *Phyllodactylus gerrhopigus*).

CONCLUSIONS. — 1) The *Latrodectus mactans* has lived in the north and south of Peru from time immemorial. At Arequipa the investigations of the author have brought it to notice for the first time.

2) This spider lives between the stones or small plants in the country ; it is most numerous in the zone between cultivated and uncultivated regions.

3) The *Latrodectus*, commonly called " lucacha ", sometimes comes into crops of wheat and alfalfa, constituting a danger for the country people when harvesting, or the animals which feed there.

4) Its bite produces in man and animals the neuro-myopathic *lactrodectism* or *arachnidism* of SOMMER and GRECO.

5) Inoculation of animals with the eggs of the spider produces, according to the dose, either neuro-myopathic arachnidism or else cutaneous hæmolytic-gangrenous arachnidism.

6) Intraperitonial mass injection is rapidly fatal.

7) Repeated bites gave a certain immunity to animals used in the experiment.

8) Fractional injections of eggs did not produced immunity, for, sooner or later, as soon as the toxic dose was slightly exceeded, the animal died.

9) The venom of the " lucacha " can be considered as a *cerebro-neuro-muscular* poison, a *thrombokinase*, a *hæmolysin*, and in the eggs a *proteolysin* in addition.

10) The venom, the eggs of the cocoons, the eggs of the abdomen of the females, and the young spiders recently hatched give venomous and hæmolytic extracts in progressively decreasing order.

11) Diagnosis is generally fairly easy to make.

12) Prognosis is variable, both owing to the effect of the venom itself, and owing to superadded secondary infections.

13) Internal and external treatment with permanganate of potash, promptly and thoroughly used, is a certain cure.

14) This remedy should always be in readiness with the country-people. It should also always be found in the outfit of the explorer.

335 – **Prophylactic Inoculation of Cattle Against Foot and Mouth Disease.** — LUTRARIO (Director General of Public Health in Italy), in *Office International d'Hygiène publique, Bulletin mensuel*, Vol. XI, Part 3, pp. 266-272. Paris, March. 1919.

The problem of immunising cattle against epizootic foot and mouth disease has always been the object of keen attention of the Department of Public Health in Italy. That Department began by making practical use of all that was generally known of the pathogenesis of epizootic foot and mouth disease in relation to immunity.

It is known that an attack of foot and mouth disease naturally or artificially caused is immediately followed by a state of immunity of longer or shorter duration. Consequently, cattle for slaughter shipped by sea from an infected area, and thus with the disease in incubation, are first inoculated at the port of embarkation ; as soon as they are well they are disinfected and shipped, with the certainty that they will not develop the disease on the journey. The advantages of this method were proved by the inoculation carried out at Salonica in 1911 on Serbian cattle

imported into Italy, by those made at Naples and Castellammare on cattle sent to Libya in 1915, etc.; however this application does not constitute a sure method from which great results can be expected in the prophylaxis of epizootic foot and month disease. For this reason the Department of Public Health has relied on wide research in the matter of immunity against epizootic foot and mouth disease.

In 1914 work was commenced entrusted to a special Committee which after became a ministerial Commission consisting of (1) Professor Alfonso Di Vestea, of Pisa University, President. (2) Professor Achille Sclavo, of Siena University. (3) Professor Alessandro Lanfranchi, of Bologna University. (4) Professor Camillo Terni, Co-Director of the Experimental Station for infectious cattle diseases at Milan. (5) Professor Mori, Director of the Experimental Station for infectious cattle diseases at Portici. (6) Dr. Angelo Parodi Delfino, of Reggio Emilia. (7) Dr. Carlo Bisanti, Veterinary Inspector General. (8) Dr. Giuseppe Cosco, Veterinary Inspector General. (9) Professor Alfredo Bartolucci, Provincial Veterinary Surgeon attached to the Department of Public Health, Secretary.

Each experimentor uses the well-equipped laboratories of the various Experimental Stations for infectious cattle diseases. Thus, those working in northern Italy use the Milan Station; those working in southern Italy have at their disposal, for want of an Experimental Station, a laboratory specially created at the Royal "Cascina" (Farm) of Poggio near Florence.

The following is a short account of the results obtained during the first 3 years of the research:—

I. — *Immunising method suggested by Professor* Terni. — This consists in strengthening and prolonging, by successive inoculations of virus specially prepared and graded, the immunity which the animals have already acquired in consequence of a first attack, natural or artificial, of the disease.

Under these conditions, inoculations with the virus cause a reaction fever without any internal symptoms of the disease and in this way generally, after 3 inoculations, super-immunity is assured against natural infection which lasts during the whole dairy period for milch cows. It is, in short, a method of vaccination with natural virus which is applied to young animals at an age at which initial infection does not cause sensible harm and when infection is easily dominated and which is continued to such a point that a degree of immunity is obtained guaranteeing the animals against all further natural infection.

This method has been frequently tested in practice; not only have the animals vaccinated been exposed with impunity to natural infection in fields and cowsheds, but quite recently, an outbreak of the disease having occurred in an experimental cowshed in the Milan district, a Station under Professor Terni himself, the vaccinated animals were all ill, to such an extent, that the farmers asked for the practical application of the method on a large scale. From experiments made up to date the following doses may be considered effective:—

(A) Intravenous inoculation. — First inoculation of 25 to 50 cc. of hysuper-immunised blood (blood taken from oxen saturated with aphthous virus) according as the animal is young or full-grown. Second inoculation 4 or 5 days later as above with the addition of 25 cc. of a solution containing 1 % of filtered virus or 50 cubic cm. of blood of fixed virulence. Third inoculation 8 to 10 days after the second.

(B) Subcutaneous inoculation. — Same inoculation as in the previous case only doubling the dose of hyper-immunised blood.

Principal theories resulting from Professor Terni's work on the pathogenesis and epidemiology of epizootic foot and mouth disease. — (1) The best and surest channel of inoculation is by the digestive organs; the penetration of the virus by other natural channels (either by the skin or by the teats) is always slower and does not cause the appearance of the general symptoms before virus is present in the rumen, the favourite seat of incubation of the virus itself.

(2) The local aphthous lesions are always the first to appear and they are noted as initial even before the fever ; by rumination the virulent matter in incubation in the rumen which spreads over the mouth infects locally the epithelial abrasions.

(3) Next appear the aphthae in the hind feet, following infection communicated by the dung which may remain unmoved for several days in the lower part of the intestines, especially if the animal is on dry fodder. The aphthae in the fore feet develop as a consequence of pollution caused by passing over contaminated litter or by the laver from the mouth of the animal. The evidence from protecting of the feet before infection is in favour of this criterion.

(4) The aphthae on the teats originate from local inoculation; the virus, present in the milk when the infection becomes general, collects round the entrance to the lactiferous canal, but at other points the aphthae are caused by inoculation by milkers who habitually lubricate the teats with the milk itself. When not milking, the aphthae on the teats are due to insect bites, dirty litter, movements of the animal's tail, etc. Careful disinfection of the teats and the hands of the milkmen and the use of antiseptic lubricants reduce the aphthous eruption on the teats to a minimum.

(5) As soon as fever shows, the blood becomes infectious for a short period, but always to a less extent than the liquids in the digestive channels.

(6) Still more important than the injuries observed in the stomachs and in the œsophagus, represented by epithelial abrasions and localised ulcers, in severe and fatal cases of foot and mouth disease, are the injuries to the small intestine especially in the duodenum and the first part of the ileum. The intestinal lesions of foot and mouth disease correspond in their histological characters, with those produced experimentally on animals by vaccine inoculated internally and with intestinal lesions of small pox in man. These intestinal lesions are very frequent and are the cause of late manifestations of infection reducing by about one half the economic yield of the animal. The absorption of aphthous virus in fatal cases de

pends on special conditions of the digestive tube, and these conditions depend in turn on excessive bulky food.

(7) The so-called re-infections at short intervals are only relapses depending, generally, on disorders of the digestive organs. Bacterial fermentation in some cases, renders the first attack of the disease abortive and hinders the production of a state of immunity, thus giving rise to true re-infections; however, a natural immunity to the disease exists and lasts for about 8 months.

Results obtained in the experimental cowshed of Poggio at Caiano (Florence). — On other lines than that followed by Professor Terni, the experimentors of the Commission are at present engaged on attempts to find a practical method of immunisation against foot and mouth disease.

In the experimental cowshed of Poggio at Caiano (Florence), to which is attached a laboratory furnished with all necessary apparatus, a Station under Dr. Cosco, Veterinary Inspector General, assisted by Dr. Aguzzi, Provincial Veterinary Surgeon of Florence, facts of considerable importance have been ascertained.

It has been possible to obtain precise evidence of the characteristic properties of the blood of animals suffering from the disease with regard to the virulence of the serum and of the red globules. These properties of the blood of aphthous animals (unknown or obscure previously) may be summarised as follows :—

The blood of aphthous animals is virulent during the whole period of fever.

The red globules and the serum of the blood of animals attacked are virulent.

The red globules after many washings in large quantities of sterile physiological solution to eliminate all trace of serum, cause infection by subcutaneous inoculation of cattle even with a dose of 1 cc.

Further research has in addition established the following :—

(1) Intro-venous injection of virulent blood corpuscles (obtained from producing animals after a series of passages until a severe clinical form is present, and after a minimum period of incubation of about 70 hours) does not cause the disease unless a certain dose is exceeded, which, in the case of the animals used in the experiments (of various breeds, aged from 12 to 18 months), is about 30 cc.

(2) An excellent dose for use in the first treatment of cattle is 25 cc.; in the second treatment it may be raised to 30 cc. cm., and in the third treatment even to 45 cc.

(3) The vaccination is followed by the typical reaction represented by a rise in temperature showing itself 1 or 2 hours after the injection and rarely later. This reaction lasts several hours (8 to 10 hours and sometimes longer) and is repeated on the following days in a less degree for several successive days (2nd, 3rd reaction). This thermal reaction is accompanied by generally very slight discomfort (flatulence, horripilation, muscular trembling) sometimes scarcely noticeable and, occasionally;

even non-existent. Generally, the thermal reaction is less marked in the 2nd treatment and is often insignificant in the 3rd.

(4) A period of 10 days should elapse between the treatments. A shorter interval may cause, at least in certain cases, a development of the disease after the 2nd treatment.

(5) Two animals which had never had foot and mouth disease, given 3 treatments according to the method indicated above, and exposed 4 months later to infection in a cowshed where there were cattle suffering severely from foot and mouth disease caused by natural infection, showed absolute resistance, while control animals were attacked in 48 hours by a severe form of the disease.

336 – **The Common Human Flea as a Parasite of Pigs in the Argentine.** — BRETHÈS, J., in *Anales de la Sociedad rural Argentina*, Vol. LIII, No. 10, pp. 443-444, 1 fig., Buenos-Ayres, July, 1919.

In the piggeries of the south and western parts of the province of Buenos-Aires, several examples of *Pulex irritans* have been found. This flea, which hitherto has only been found on men, dogs and cats, is very abundant in the Argentine on pigs, and particularly, on sucking-pigs. The eggs are found in the litter.

From an examination of the scientific literature on the subject it appears that hitherto only one other kind of flea, *Dermatophilus penetrans*, has been found on pigs.

To exterminate these parasites the author advises the construction of cement piggeries, which should be kept very clean.

337 – **Aspergillosis of Poultry.** — HITIER, in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. V, No. 37, pp. 951-952. Paris, Dec., 3 1919.

M. HITIER presents to the Accademy a report by M. LE COMTE DELAMARRE DE MONCHAUX on aspergillosis of poultry in which the author sums up a communication made by him to the Avicultural Section of the Société des Agriculteurs de France.

This mycosis, regarding which there is scarcely any mention in avicultural treatises, has been noticed in a great number of species: — geese, turkeys, swans, ducks, chickens, pigeons, etc. Man himself is not exempt, as is proved by the pseudo-tuberculosis of pigeon feeders, studied by RÉNON.

The *Aspergillus fumigatus* responsible for this disease, named in 1863 by FRESENIUS, had already been described and illustrated in colour by DESLONGCHAMPS in 1841.

Very common in nature in a saprophytic state, it gives rise, according to the author (under the influence of causes still little known, for example of a wound which gives them entrance into the organism and circulation), to pathogenic strains which develop in the bird with a great power of growth and cause an infection the results of which are generally fatal.

The object of the author has been specially to draw the attention of breeders to a disease which is often unperceived and for which the right remedy has yet to be found.

338 – **The Use of Naphthalene as a Remedy Against Chicken Lice.** — ABBOTT, W. S., in *Journal of Economic Entomology*, Vol. XII, No. 5, pp. 397-402. Concord, N. H., Oct. 1919.

The author has experimented with various preparations of naphthalene as a means of destroying chicken lice of the species *Menopon biseriatum*, *M. pallidum*, *Lipeurus heterographus* and *Goniocotes abdominalis*. The naphthalene used for dusting in the feathers a powder containing 5 % of naphthalene is ineffective, but a powder containing 10 % is very effective; it causes, it is true, slight discomfort but this is quite temporary and after 5 to 10 minutes the fowl no longer feels any ill effects.

By thoroughly rubbing powder containing 60 to 100 % of naphthalene into the feathers there is risk of killing the fowls; on the other hand, powders of the same strength lightly dusted over the feathers cause no permanent injury.

A suitable method for reducing considerably the number of lice consists in sprinkling finely powdered naphthalene over the fowls when they are roosting at night; but this method requires further testing.

Balls of naphthalene placed in the nest had no effect in diminishing the number of lice on the hen setting or laying there, but they injured the hens and prevented them from setting well and seemed to have a toxic effect on the eggs and newly hatched chicks.

339 – **Eradication of the Depluming Mite of Chickens by One Treatment.** — WOOD, H. P. in *Journal of Economic Entomology*, Vol. XII, No. 5, pp. 402-404. Concord, N. H., Oct. 1919.

The author has reported that the depluming mite of chickens (*Cnemidocoptes gallinae*) can be completely eradicated by a single treatment of one of the following: =

Lime-sulphur bath: 1 pound of lime + 2 pounds of sulphur + 1 gallon of water; dilute the mixture in 20 parts of water.

Tobacco sulphur bath: 3 teaspoonfulls of " Black leaf 40 " tobacco extract + 6 ounces of sulphur + 2 ½ gallons of water.

Arsenical bath as used for destroying ticks in cattle.

Sodium fluoride and sulphur bath: ¼ ounce of sodium fluoride + 2 ounces sulphur + 1 gallon of water.

Sodium fluoride, sulphur and soap bath: ¼ ounce of sodium fluoride + 2 ounces sulphur + sufficient soap to make the water soapy + 1 gallon of water. This bath destroys not only the depluming mite but also lice.

Kerosene emulsion is effective against the parasite but is injurious to the fowl treated.

340 – **Glutinated Maize Bran.** — CONSOLANI, G., in *Il Coltivatore*, Year LXVI, No. 1, pp. 10-12. Casale Monferrato, Jan. 10, 1920.

FEEDS AND FEEDING

Glutinated maize bran is that which remains of the grain after the starch has been extracted from it, and compared with maize, a food with a more narrow that is to say concentrated, nutritive ratio.

After having been hulled by means of brush cleaners, the maize is put to soak in vats containing water at 45° to 50° C. in which sulphurous anhydride has been stirred. After soaking for 3 days the maize is crushed

in special mills, and passed under a continuous jet of water into cement basins where it undergoes a second soaking. Then it is passed into extractors, through which the starch flows in the form of milk and is separated from the residues of the grain. These pass into a second mill where they are re-ground, then into a second extractor, where they undergo the same process as in the first. Thus the bran is separated, which contains already a little gluten, and which is pressed in hydraulic presses, then dried.

The starch, separated by the extractors in the form of milk, is led into vats, furnished at the bottom with several tubes, each of which is above a hair sieve of very close mesh. The glutinous part of the maize, which was mixed with the starch, remains in these sieves, after which it is passed into other special sieves, where it undergoes a washing under a continuous jet of water, with the object of allowing any remaining starch to pass. Finally the gluten is pressed in filter-presses, dried, and mixed with the bran previously separated.

Whole maize, maize bran and glutinated maize bran (analyses made by the Agricultural Station of Modena of a sample prepared at the starch factory at Massa Superiore, Rovigo) have respectively the percentage composition shown in the following table: —

	Grains of maize	Maize Bran	Glutinated maize bran
Water	13.00 %	13.20 %	9 40 %
Pr tein	9.88 »	14.10 »	23.99 »
Digestible albumen	6.6 »	9.8 »	18.6 »
Nitrogenous-free extracts	69.24 »	56.00 »	47.37 »
Fat	1.40 »	3 70 »	13.05 »
Ash	1.30 »	5.80 »	1.36 »
Cellulose	2.18 »	7.20 »	4.83 »
Nutritive ratio	9.44 : 1	4.6 : 1	3.7 : 1
Commercial units	93.70	83.57	about 130

Glutinated maize bran constitutes, therefore, an excellent food, which should be widely used. Feeding tests with this product have always given good results. It is suitable chiefly for the fattening of cattle and pigs, for the feeding of milch cows, young animals in general, and poultry. It is fed in quantities of about 1 kg. per day to calves, 2.5 to 3 kg. to large cattle, and 0.5 to 1 kg. to pigs. As it is a very dry food, it should be moistened with water, salt for preference, so as to form a mash. It is an excellent ingredient for porridge.

The sale price of glutinated maize bran being less than that of ordinary wheat bran, it is, therefore, one of the most suitable concentrates from an economic standpoint.

HORSES

341 – **Feeding Work-Horses in the United States.** — Bell, G. A., and Williams, J. O in *Farmer's Bulletin* 1030, U. S. Department of Agriculture, pp. 1-24. Washington Dec., 1919.

The authors state that the selection of the most suitable rations fo working horses is governed largely by local conditions, and they dea

with (*a*) the influence of local conditions ; (*b*) the conditions which determine the selection of foods and their combination to obtain the correct proportions of their nutrient elements ; (*c*) the method of adjusting the rations for light draught horses and heavy work-horses They then pass in review the principal foods and finally give a list of rations previously fixed per 1000 pounds live weight for resting horses and for horses on light medium, and severe work respectively. This list is reproduced in the Tables which give an idea of the typical rations for agricultural horses used in the United States:—

342 - **Cattle-Feeding on Pasture in the United States.** — Cochel, W. A., in *The Breeders' Gazette*, Vol. LXXVI, No. 8, pp. 307-308,1 fig. Chicago, Aug. 21, 1919. CATTLE

Description of the methods of feeding butchers' cattle on pasture adopted in the principal pasture areas in the United States, with a list of the types of grasses most commonly used for supplementing the grain ration given to cattle. Blue grass (*Poa pratensis*), with the white clover which accompanies it, is the standard pasture grass of the older farming parts of the United States. In the south, pastures of Bermuda grass (*Cynodon Dactylon*) predominate, accompanied by *Lespedeza striata*. On the Pacific slope the standard pasture is of *Alopecurus* and *Medicago falcata*. The grass lands of the Flint Hill region (Kansas) and the Osage Country (Oklahoma) are of bluestem (*Andropogon furcatus*) and side-oat gramma (*Boutelona oligostachya*), while the plains region, known as the Short-Grass country, is the home of buffalo grass (*Buchloe dactyloides*) and of the short gramma. The two last mentioned grazing areas are not provided with leguminous plants and are, consequently, chiefly used for grazing mature steers or for maintaining breeding herds.

Pastures of *Poa pratensis* are much used for fattening yearlings ; calved in spring, they are turned out to pasture about May 1 in the following year for sale about the end of the summer or early in the autumn. While the grass is tender the cattle consume only about 10 pounds of grain daily per head ; when the grass loses its succulence the appetite for grain increases, and they consume double that quantity. When the consumption of grain increases, it is advisable to use from 1 ½ to 2 pounds of nitrogenous concentrates per head daily, which gives the cattle a much better finish than is obtained from the ration pasture + maize grain, so that at the beginning of October the animals reach a weight of from 1100 to 1200 pounds and fetch the highest market prices.

Another system fairly generally followed is to half-feed two-year-old steers during the winter, then, in May and June they are grazed without any supplementary grain ration ; full feeding commences in July and continues up to the end of September or the beginning of October. Another system is to winter the cattle, as much as possible, without grain ; they are turned out to graze at the beginning of May without giving grain until the grass begins to fail ; then a supplement is given of maize grain, or in favourable years green maize ears fed directly in the field, in gradually increasing amounts. With this system the animals attain a high finish by the beginning of November.

In grazing districts where leguminous plants do not abound, cottonseed cake is generally fed instead of maize grain. The cattle used in these districts are generally older than those used in the bluegrass pastures. They are frequently half-fed during the winter so that they may go on grass in a high condition in spring, and be ready for market towards the end of June or early in July before the abundance of cattle in the market depreciates prices.

A frequent practice on natural pastures, which are at their best in July and August and fail utterly after the first hard frosts, consists in taking off the cattle at the beginning of September and keeping them for 60 to 90 days on a fattening ration without pasture, so as to sell them when the greater number of animals handled under similar conditions has been marketed. This method gives very good results with high grade steers.

343 – **Feeding Dairy Cows with Purchased Foods only, in California.** — WALL, F. W. (University of California), in *Hoard's Dairyman*, Vol. LVIII, No. 1, pp. 5-7, 9 fig. Fort Atkinson, Wis., July 25 1919.

The author investigated, as an example of a dairy where the animals are fed exclusively on purchased food, a dairy establishment situated near Los Angeles (California), belonging to a creamery company ; which has a herd of 330 Holstein cows.

The cows are rigorously selected, those whose production is inferior being discarded ; a daily production of over 300 pounds of butterfat is thus obtained for the whole herd, which includes 20 % of two-year old heifers with their first calf.

The feeding system is as follows:— All cows receive, in racks, alfalfa hay or green alfalfa. Dry cows are given only maize silage in addition. Cows at the beginning of lactation, which are milked twice a day, receive, in addition, about 14 pounds of concentrates per head daily, namely a mixture of 5 pounds of dried beet pulp + 5 pounds of wheat bran + 4 pounds of coconut meal ; cows in full lactation, milked 3 times a day, receive an additional 4 pounds of a mixture of equal parts of wheat bran, rolled oats and barley. The quantity of grain given is gradually decreased as the milk flow decreases so as to feed approximately one pound of grain for every 3 ½ to 4 pounds of milk produced.

To belong to the group milked 3 times a day, young cows must produce at least 30 pounds of milk per day and mature cows at least 40 pounds. The average production of butterfat for the cows milked 3 times a day is 2 pounds and for those milked twice a day 1.5 pounds.

The milch cows consume, on the average, 15 to 18 pounds of alfalfa hay (or its equivalent green) and 20 to 25 pounds of maize silage per head per day. The relatively low amounts of roughage and high amounts of concentrates are justified by the fact that the former, delivered at the dairy, has such a high cost that it exceeds that of the latter, on the assumption (which is justified) that 2.2 tons of good alfalfa hay have a similar feeding value to 1 ton of mixed grain.

The prices of foods in dollars per ton are as follows :— Alfalfa hay, 22.10. Green alfalfa, $5.00. Maize forage ($3.50 a ton) + transport nd handling at silo ($1.50 to $2.00 a ton), $5 to $5.0. Dried beet ulp and wheat bran, $45. Rolled barley, oats and cocoanut meal, $60.

The maize silage is fed at milking time together with the grain ration. 'he alfalfa hay is cut into ¼ to ½ inch lenghts which effects a saving f 25 %.

The dairy is associated with the local county cow-testing Association. 'he grade cows (which are gradually being replaced by pure-breds) are hus sold with a guarantee of a minimum production of butterfat at good rices and to the satisfaction of the purchaser.

Another good source of revenue is the sale of calves. The calves get p to 6 quarts of whole milk a day, in individual pails, for 6 to 8 weeks, nd are then gradually accustomed to skim-milk supplemented with good lfalfa hay and a mixture of bran, oats and barley with a little coconut neal ; the mixture is increased gradually from a fraction of a pound to or 3 pounds per head daily. When they have reached a suitable age, he calves are sent to hill pastures, with bred heifers, for 5 months.

44 – **Experiments on the Food Value of Clover versus Alfalfa for Milk Production in Ohio.** — HAYDEN, C. C. in the *Bulletin of the Ohio Agricultural Experiment Station*, No. 327, pp. 1-36. Wooster, Ohio, July, 1918.

Experimental tests were conducted at the Agricultural Station of)hio (United States) chiefly owing to the difficulties of alfalfa cultivation n a considerable part of the eastern territory of the Ohio State, because f the type of soil and the scarcity of drainage systems These difficulties re the most noticeable in the North-east of the State, which specialises nore in the milk industry. The cultivation of clover does not, on the ther hand, present any difficulty, provided that there is sufficient lime.

PLAN OF THE EXPERIMENTS. — As many cows as were available ere used for feeding tests each year ; and they were divided into two ots as nearly comparable as possible Each of them received alternately, lfalfa and clover, making the feeding periods as long as possible Exclu- ive of the hays, the rations were identical in quality. To prevent he leaving of feed not selected by the animals, rations were given in re- ular proportions, to be cleaned up entirely. These tests were repeated years in succession.

RESULTS OF THE TESTS. — The adjoining Tables show the quan- itative data relative to the 4 series of tests. Table I shows that, on the hole, more food was consumed and more milk produced while the cows ere on the alfalfa rations, but that the difference in the quantity of feed onsumed, was greater than the difference in quantity of product. The reatest difference in milk was noted in the first test when the clover was f the poorest quality.

The alfalfa rations contained 31.8 % more protein than the clover ations, and 8.2 % more carbohydrates and fats ; however, the cows on lfalfa produced only about 9.5 % more milk ; and this difference would ave been still less if the clover in the first test had been of good quality.

The average nutritive ratio during the four tests was 1 : 8.6 for clover rations and 1 : 7 for alfalfa rations. Both these rations were lower in protein than the accepted standard, therefore there was not any over-supply of protein with the alfalfa. Theoretically, the alfalfa should have caused greater production per unit of hay, especially when the quality of the two hays is considered.

The gain or loss in weight of the cows, which are fairly high, should be taken into consideration. In Test I, the cows on clover lost in weight about 1 pound daily, whilst those on alfalfa gained about 0.7 pound daily. In Test II, the cows on clover lost about 0.7 pound daily, and those on alfalfa gained in the first period and lost in the second, an average loss of about 0.1 pound daily. In Tests III and IV, the final differences in weight were less obvious, and this partly explains the fact that the clover was of the second cutting, harvested in full bloom. It is obvious also that the cows selected for the tests were in the early part of their lactation periods, when the tendency to draw from their bodies is strongest if the supply of nutrients is short in the feeds. This would be the case with the poor quality clover rations from the point of view of proteins.

Conclusions. — Alfalfa appears to be a better digestive than clover, with more stimulative action. When the hays are of equal quality, neither can be said to be greatly superior for milk production, but the alfalfa showed a stronger tendency to miantain the weight of the animals.

Table I. — *Summary of milk production and food consumption in 4 tests.*

The clover rations showed a smaller amount of digestible protein consumed per 100 pounds of milk produced. It is probable that the cows may have drawn on a certain amount of their organic nutritive reserves to supply the deficit; for 100 pounds of milk produced, the total nutrients consumed were a little greater with the alfalfa rations.

The superiority of the alfalfa over the clover lies chiefly in the fact that: — (1) it makes it possible to obtain a stronger production; (2) it has an appetising effect rather than a high protein content. The results of these tests indicate that a unit of clover protein is more efficient in milk production than a unit of alfalfa protein.

The analytical data of the test results is given in an appendix containing 36 individual summaries.

45 – **Variations in the Quantity of Milk Produced by Ayrshire Cows and its Fat Content.** — PEARL, R. and MINER, J. R., in *Journal of Agricultural Research*, Vol. XVII, No. 6, pp. 285-322, 6 diagr., bibliography of 30 works. Washington, Sept. 15, 1919.

For a genetic study to be critical, it is essential that it should be based on a sufficiently comprehensive knowledge of the normal variations of the character considered, independently of factors of genetic significance. This consideration becomes particularly significant when the character in question is subject to conditions of environment, as is specially the case in the milk production of cows.

The authors have, consequently, undertaken a biometrical analysis of the normal variation in the quantity of milk production of Ayrshire cows

per unit of time and in quality as indicated by the butter fat content. Their aim was to establish normal constants for inter-individual variation in these characters which would serve as a basis in future genetic studies on milk production.

The investigation was based on the records of production of Ayrshire cows published in the Reports of the Ayrshire Cattle Milk Records Committee of Scotland, compiled by SPEIR and HOWIE. These Reports contain :— Total quantity of milk produced (in gallons); Average percentage of fat, determined by periodic tests; Total quantity of milk calculated on a 3 % fat basis; Number of weeks in lactation period; Age of the cows; Date of last calving; Miscellaneous information about the cow, particularly of abnormal circumstances of any sort during the test. The Report for 1908 includes 8132 cows and that for 1909 includes 9202.

The authors deal, in a series of Tables and diagrams, with the following points, which are then discussed. — Frequency distributions for variations in average weekly milk yield of Ayrshire cows of different ages; Frequency distributions for variations in percentage of fat in the milk of Ayrshire cows; constants for variation in weekly milk yield; constants for variation in percentage of fat in the milk; coefficients of variation for various characters; analytical constants for variation in average weekly milk yield; constants for variation in fat percentage; constants of the component normal curves in the variation in average weekly yield; comparison of average weekly yields at different ages with those calculated on the assumption that the change is logarithmic; average fat percentage at different ages.

RESULTS. — (1) The average weekly yield and fat percentage of the milk change in a considerable degree and in a definite manner with the age of the cow.

(2) The weighted average standard deviation and coefficient of variability for average weekly yield of cows of any given age are 2.806 gallons and 17.081 % respectively. These values may be considered as very close approximations to true normal values. For cows of all ages, taken collectively, the corresponding values are 3.329 gallons and 20.816 %.

(3) For fat percentage the weighted average values for cows of any given age are: — Average, 3.738; standard deviation, 0.330; coefficient of variation, 8.827.

(4) About one half of the variation in milk production results from varying genotypic individuality of the animals with respect to this character: the other half results from varying influences of environment.

(5) Milk production curves, analytically considered, tend definitely to a positive skewness, both for yield and quality. The weighted average value of the skewness for average weekly yield is + 0.1047 and that for fat percentage is + 0.1338.

(6) Selection can have had little or no influence in determining the direction or the amount of skewness in the milk production curves.

(7) The curves for milk yield tend, on the whole, to be more frequently

unlimited range types, while those for fat percentage tend more to nited range types. The estimation of range limits given by the theoretical curves is, on the whole, good.

(8) In general. the tendency of milk yield curves is toward the leptokurtic condition, that is to say, they are more acute then the corresponding normal curves. Fat percentage curves do not show any definite tendency th respect to kurtosis.

(9) Certain of the milk yield curves were dissected into two normal rves by PEARSON'S method. The resulting graduation was not so good that given by the appropriate, unimodal skew frequency curve. There no evidence that variation curves for milk production curves are omodal.

(10) The change in average weekly yield of milk with advancing e is represented by a logarithmic curve and is in accordance with a w which may be stated in the following way :— The absolute amount milk produced per unit of time increases with the age of the cow until e maximum is reached, but the rate of increase diminishes with advancing e until the absolute maximum of production is reached. After the ne of maximum productivity, the absolute production per unit of time creases with advancing age at a continually increasing rate.

(11) The average fat percentage of the milk diminishes with advancg age until the cow reaches her 10th year. Thereafter the fat percentage mains approximately constant during the remaining lactation periods.

5 – **Lamb Feeding Investigations in Kansas, in 1919.** — PATERSON, A. M., in *Agricultural Experiment Station, Kansas State Agricultural College, Department of Animal Husbandry, Circular* No. 79, pp. 4, 1 fig. Topeka, Oct. 1919. SHEEP

250 lambs were bought in the Kansas City market at $16 per cwt., nt to Manhattan on Feb. 26, 1919, and fed on silage and maize dder up to March 9; they were then divided into 7 lots of 35 ch and submitted to a food test lasting 49 days. The initial ration r each lot of 35 heads was 6 pounds of grain + 2 pounds of protein pplement + 20 pounds of alfalfa hay + 35 pounds of silage. Lots hich received no silage were given 40 pounds of alfalfa hay per day. The itial ration was gradually increased, care being taken to see that it as always entirely consumed. The lambs were quartered in an enosure provided with a shed and had access to fresh water and salt at times.

The more important data relating to this test are given in the follow- Table. The cost of the foods were :—

(1) Maize silage made in August from maize injured by hot winds.

RESULTS. — (1) Linseed meal is more efficient than maize glute feed as a protein supplement for fattening lambs when fed with mai grain, alfalfa hay, and maize silage.

(2) The addition of linseed meal or cottonseed meal as a protein su plement to a ration of maize grain, alfalfa hay and maize silage, reduc the cost of production per unit gain of live weight, and increased t selling price per unit and the profit.

The addition of maize gluten feed as a protein supplement to a r tion of maize grain, alfalfa hay and maize silage, increased the gain

eight, diminished slightly the cost of gain per unit of live weight, but iled to produce the desired finish and gave less profit than when no pro- in supplement was used.

(3) The substitution of hominy feed for maize grain with a ration of falfa hay and maize silage increased slightly the gain in live weight, but so increased the cost of that gain. It also failed to produce the high nish that maize grain did, which made the ultimate profit less.

(4) Maize silage added to a ration of maize grain and alfalfa hay was ot profitable except when linseed meal was added, in which case the ghest profit was obtained.

(5) Linseed meal substituted for maize grain and fed with alfalfa hay id maize silage increased the live weight slightly more than when maize ain was fed with alfalfa hay and maize silage, but the former ration iled to produce the required finish and the sale price per unit of weight as so much less that there was a loss per lamb.

7 – **Breeding and Commerce of Pigs in South Annam** (1). — SCHEIN, H., in *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 12, pp. 369-376. Saïgon, Dec., 1919. PIGS

The breeding and export of pigs forms an important branch of agriculture and commerce in South Annam at the present time.

HISTORICAL. — The Moïs tribes bred pigs for their food from time immemorial, without having ever made an important trade of it. On e other hand, the Chams, by religion Braminists and later Mahomedans, oscribed all contact with this " unclean " animal, whose breeding could ot be revived in the coastal deltas until after the sanguinary wars which ided with the victory of the Annamites.

But this breeding has only recently expanded to its present limits owing the peaceful penetration of the Chinese at Singapore. Although great ork-eaters, the Chinese of the Malay Peninsula scarcely breed any pigs, eing employed as coolies in the tin mines, on plantations and in factories. xcept Southern China, and Indo-China (French, British or Siamese) ie other countries near the Malay Peninsula regard the breeding of pigs id their use as food with disapproval. Indo-China is thus, in conjunction with China, Siam and Burma, indicated as pork provider of the Chinese in Singapore.

BREEDS OF PIGS. — The breeds of pigs in South Annam are the same s in the whole of Indo-China. They have been well described by . BAUCHE (The Pigs of Indo-China, *Bulletin économique de l'Indo-hine*, 1902, p. 841), so the author only gives a few details on this subject.

(1) This article forms a useful supplement to the paper by M. DOUARCHE on " Indo-Chinese Breeding ", summarised in *R.* March, 1919, No. 233, which deals with breeding in general id especially that of cattle. As for sheep, " they are ", M. DOUARCHE says, " practically on-existent in Indo-China and there is scarcely any chance of their increasing there ". On ie other hand, an article by M.M. AUG. CHEVALIER and P. A. LAPICQUE, dealt with in *R.*, ct.-Dec. 1919, No. 1199 sketches the future possibilities of pig breeding on a large scale in ndo-China; that article also deals with the utilisation of " luc-binh " or water hyacinth, hich abounds throughout the Colony, for fattening pigs. (*Ed.*)

They are, or rather were, 3 in number.

(1) *Delta or Tonkinese breed.* — A small pig, concave, sub-brevilinear. 20 years ago this was the commonest breed in the Annamite villages. It has so completely disappeared since then, that out of about 7000 pigs exported, not one of this breed was seen in 1919; hardly any of the animals examined seemed to show traces of cross-breeding. This fact is apparently due to several causes:— small size; decidedly inferior quality of meat and lard, soft, flabby almost hydrohaemic; voracity; probably less resistant to sporadic or epizootic diseases. Owing to its defects the disappearance of this breed is not a matter for regret.

(2) *Pigs of high regions* (*Muong pig, Moïs pig*). — Animals of medium size with straight, longilinear profile, with slender legs. Head conical, distinctly elongated; the narrowness of the snout is at once noticeable.

The coat is usually entirely pigmented. But pigs with black skins and white bristles are sometimes seen (about 0.33 %) or with tawny bristles, like the wild boar (about 1 %), or presenting some slight traces of depigmentation of the derma (about 2 %), especially on the snout and on the lower part of the belly. However, the depigmentation is not complete, for the skin is always slightly brownish.

Furthermore, in the Moïs and Tonkinese breeds the pigmentation of the derma is not the same as in the Chinese pig; in the latter the pigmented parts are clearly black with a bluish reflection, while in the two former breeds the coloration is very dark brown with a red reflection.

Although closely related to the wild pig, from which it must have directly descended, the Moïs pig is much quieter in character than the Chinese pig, which is, on the other hand, much further removed from the wild animal. They can be loaded loose in trucks, which is absolutely impossible for Chinese pigs.

The Moïs pig is very hardy; it eats little and fattens slowly. It can, however, reach a considerable size: the author has seen in a Moïs village one of these pigs which must have weighed 200 kg,, but this animal appeared to be 3 years old and the author thinks it would be unprofitable to keep a pig so long. Generally pigs are sold at 14 to 16 months old weighing from 60 to 100 kg., sometimes even 120 kg.

The meat is of good quality and the lard fairly firm. The Chinese exporters prefer pigs of this breed and offer a slightly higher price for them, since being hardy and small eaters they can stand the voyage, during which they are inevitably badly fed. A Chinaman told the author that with this breed of pig the losses were 15 % less than those of pigs of Chinese breed.

(3) *Quang-Si breed.* — A little below medium weight; profile straight sometimes slightly concave; sub-brevilinear, stouter legs, wider snout and shorter body than in the preceding breed; back straight, sometimes slightly saddle-backed; the author has not noticed that the loins are badly set on; coat piebald with the white parts of the skin distinctly light pink; the pigmented parts clearly black.

The Quang-Si pig is less hardy than its Moïs relative, eats mor

but fattens quicker and easier ; pigs weighing 120 kg. at 14 to 16 months of age are frequently met with. The author thinks that this weight would become general if the pigs were given as much food as they could eat ; he has never seen very old specimens of the breed and cannot estimate what their maximum weight might be.

Breeding. — The breeding is certainly rationally carried out by the Annamites, for it is the only work in which they have realised division of labour. Certain natives own a boar whose services are hired ; others keep sows and sell the produce, but most buy young pigs and fatten them. The agricultural speculations are consequently clearly separated in the matter of pig breeding.

The sow is covered at her owner's place where the boar is kept for 2 or 3 days. When the boar is 2 years old he is castrated, fattened and sold to the local butcher. The sows may have litters of 6 to 12 young ones, rarely 13. The Annamites are present at the littering and give the sow and the young pigs the care required. The sow is covered when she is in season some weeks after littering. She litters 3 times only to avoid risk of weak offspring from a fourth bearing, and is then spayed ; she is then fattened as well as can be, for these sows are not easily fattened.

The young pigs, weaned at 2 ½ months of age, are sold to the fattener at a rate of 2 or 3 *piastres* the pair when the market for pigs is assured by export. They then weigh from 3.5 to 4 kg. The fattener keeps them for 10 to 14 months and then sells them to the butcher or exporter. The average weight of these animals is 1 *picul ;* the market value per *picul* varies from $9 when local consumption forms the only market, to $12 when export is brisk.

Pigs are kept in nearly every Annamite house, generally in a satisfactory state of cleanliness. The pigs roam all day long round the house looking for scraps ; they are fairly well fed with paddy husk, dust of rice husk, cut-up stems of banana plants, cut grass, refuse from the preparation of dried fish, brewers grain, maize (this cereal is much used as food by the Moïs, but the Annamites only use it in case of scarcity, because if maize predominates in the ration, the lard of the pig acquires a yellowish colour).

Domestic pig keeping brings little gain to the Annamite. A system of farming on a share principle even exists with the Chinese, in which the Annamite, unqualified to fix costs, works at a loss and which happily tends to disappear. The Chinaman hands over to the Annamite a pair of young castrated pigs, imported from China by sea and the Annamite undertakes their feeding and maintenance ; the following year they share : — one pig to the farmer and the other to the Chinaman.

The Chinese scarcely ever export any but castrated animals, just as formerly they prohibited the export of silkworm eggs. They try, in fact, to keep the monopoly of improved breeds of animals. The Annamites readily make the comparison of the selfishness of the Chinese with the disinterestedness of the French who strive to introduce into the country everything that can improve local production.

Owing to the shortness of the voyage (2 or 3 days during the north

monsoon), the importation of live animals may lead to the introduction of infectious diseases, specially cattle plague, which is endemic in southern China ; fortunately pigs and cattle are not intimately associated so that the risk of infection is partially limited, but as infection is possible, preventive measures should be taken.

Diseases. — Unlike Central Annam, diseases of pigs are fairly rare in the South : few are verminous or parasitic. Measly pigs are few in number (about 2 %); Moïs pigs are most subject to this disease, owing to the fact that they are village scavengers.

Pig plague is fairly frequent, but when this disease rages the Annamites eat dead and infected animals without giving notice. It is therefore very difficult to follow the progress of this disease among the natives, so that the author has only been able to investigate it on the farm of an European. It is a seasonal disease which is seldom noticed except in May, June and July, in the hot season ; it is said to disappear in September and for the last 5 years it has not appeared in the Nhatrang district.

Export of pigs. — Export from South Annam is chiefly made in junks. Sometimes, however, merchants have bought pigs in the Nhatrang district and have sent them by rail to Saïgon for shipment by steamer. This method of transport is no longer used, in spite of its quickness, because the mortality among the pigs was apparently too high. The pigs, placed in the hold, probably did not get sufficient air; it is also possible that they did not receive the same care, on the steamer however rough, that they get from the crews of the junks.

The losses in transport by junk are very slight, 5 to 10 % on the average. The profits made by the Chinese engaged in the trade are handsome : the *picul* of pig, bought in Annam at a maximum of $12, is sold at Singapore for $30 to 40.

The fact that the pigs are deck cargo, compels the loading of heavy goods in the hold of the junks. Salt is in these conditions an ideal cargo, for it is in fair request at Singapore, though the rates vary very much from year to year. The junks engaged in the export of pigs frequent ports where salt can be obtained, so that ports serving populous districts, consequently with important trade, ought always to have warehouses of salt for export.

POULTRY

348 - **Genetic Studies in Poultry : Inheritance of Leg-Feathering.** — Punnett, R. C. and Bailey, P. G., in *Journal of Genetics*, Vol. VII, No. 3, pp. 203-213. Cambridge May, 1918.

Results of experimental crosses between a breed with feathered legs (Langshan) and breeds with naked legs (Brown Leghorn and Gold-pencilled Hamburgh).

Generally the F_2 fowls had slightly feathered legs; but there was considerable variation and one of the hens from a cross with the Hamburgh breed had naked legs, and although crossed with a cock with naked legs, she produced progeny with feathered legs.

The F_2 generation of the cross with the Leghorn breed comprised 323 chickens with feathered legs and 106 with naked legs; the F_2 genera-

ion of the cross with the Hamburgh breed comprised 117 chickens with eathered legs and 31 with naked legs. There was, therefore, a close approach o the ratio 3 : 1.

Fowls of the F_2 generation were, as far as could be judged, identified s homozygous for the character " leg-feathered ". A few F_2 fowls were even heavier leg-feathered than the Langshan breed. Chickens with noderately feathered legs crossed with chickens having naked legs very often produced chickens with heavily feathered legs ; in these cases greater number of cocks were feathered in this way than hens. The author elies on the hypothesis of modifying factors to explain these facts.

On the basis of the data recorded by DAVENPORT the writer suggests hat the character " leg-feathered " in Cochin-China and Dark Brahma breeds depends on 2 factors.

349 – **Sterility of Hybrids between the Pheasant and Gold Campine Fowl.** — CUTLER, D. W., in *Journal of Genetics*, Vol. VII, No. 3, pp. 155-165 + 1 pl. Cambridge, May, 1918.

The author has made cytological investigations on the testes of a dozen ybrids obtained by crossing pheasant cocks and Gold Campine hens ; he has further studied the spermatogenesis of both the pheasants and Gold Campine cocks.

Technical difficulties rendered the determination of the number of chromosomes uncertain. The hydrids had from 18 to 20 in the spermatogonia, the pheasants from 20 to 22 and the Gold Campine cocks from 18 to 20. The early development of the primary spermatocytes is normal ; a granular spireme is formed which retracts to one side of the nucleus, producing a closely packed mass of threads. In the next stage spermatogenesis becomes abnormal. The synaptic threads, instead of breaking into bivalent chromosomes, form a varying number of irregularly shaped clumps of chromatin. There is no uniformity as regards the number of the clumps produced, and a series can easily be formed in which the number varies from 2 or 3 large masses up to the condition where the chromosomes are almost all bivalent, or where many have separated as univalents. This failure of the synaptic threads to form bivalent chromosomes is evidently the cause of sterility in the hybrids. This is the final stage in spermatogenesis, for divisions of the primary spermatocytes do not occur, neither is there any trace of abnormal mitosis. There is neither the formation of giant spermatids, as recorded for hybrid pigeons by GEOFFREY SMITH, nor production of multiple spindles, as found by GUYER in hybrid pigeons and by WODSEDALEK in the testicles of a mule.

350 – **Note on Indo-Chinese Birds whose Feathers are used by the Annamites or are Exported.** — DEMANGE, in *Bulletin économique de l'Indochine*, Year XXII, New series, No. 138, pp. 710-728 +12 plates Hanoï-Haïphong, Sept.-Oct., 1919.

Desiring to introduce a little precision into his notes on feather fans and hats, published under the title of " Little Trades " in the *Bulletin*

économique de l'Indochine (Year. XXI, No. 131, July-Aug., 1918), the autho has been led to interest himself in birds, principally aquatic birds, whic are the object of a fairly important trade.

A basic investigation enabling the different kinds of birds and th different genera of the group of "Crab-eaters" (the most importan among the feather producing waders), to be distinguished, was of chie importance, for the value of feathers varies considerably from one specie to another.

The author has succeeded in unravelling to a great extent the histor of ornamental feathers, and that of the birds which produce them. He has used the work of DR. G. TIRANT, *Les oiseaux de la Basse-Cochinchine* and the *Décades Zoologiques* of the Scientific Mission of Exploration in Indo-China. He has reproduced the complete synonymy and the principal information given in these two somewhat inaccessible works.

The observations which he has made himself in Tonkin are not always in agreement with those of Cochin-China, which is not surprising the two countries each having certain species which are peculiar to them geographical races and varieties must perforce be created.

For the correct use of the vernacular names, the fixing of the pric of feathers, their method of use, the author had recourse to various maker of hats and fans, and to the native bird-catchers.

The number of birds dealt with by the author in the present not is 38, of which 14 are Ardeidae (herons and crab-eaters) The followin is the list (recognized scientific names and common names) : —

PICIDAE : *Centropus sinensis*, greater cuckoo or pagoda cock.

ALCEDINIDAE : — 1) *Alcedo bengalensis* and 2) *A. meningting*, lesse Kingfishers ; 3) *Entomolia pilcata*, black-hooded, white-necked Kingfisher 4) *T. smyrnensis*, brown-hooded Kingfisher.

ORIOLIDAE : *Oriolus indicus*, Indian oriole.

CORVIDAE : — 1) *Corone insolens*, black rook ; 2) *C. macrorhynch* white-necked rook ; 3) *Urocissa sinensis*, Chinese jay.

PHASIANIDAE : 1) — *Pavo muticus*, peacock; 2) *Polyplecton germai* spur-fowl or polyplectrum ; 3) *Numido meleagris*, guinea-fowl.

GRUIDAE : — *Grus antigone*, ash-coloured crane.

ARDEIDAE : 1) — *Ardea cinerea*, ash-coloured heron ; 2) *A. sumatran* grey heron ; 3) *A. purpurea*, brown heron ; 4) *Herodias trorra*, great white egret ; 5) *H. garzetta*, lesser white egret ; 6) *Bubuleus coromandu* buffalo heron ; 7) *Ardeola prasinosceles*, common crab-eater ; 8) *grayi*, white crested crab-eater ; 9) *Gorsachius melanophus*, bittern ; 1 *Nycticora griseus*, common night heron ; 11) *Butorides javanica*, gre bittern or barred heron ; 12) *Ardetta flavicollis* black bttern ; 13) *Acini momea*, cinnamon bittern ; 14) *A. sinensis* Chinese bittern.

CICONIIDAE : — *Leptoptilos javanica*, black-legged marabout.

TANTALIDAE : — 1) *Tantalus leucocephalus*, white-headed tantal 2) *Ibis melanocephala*.

RALLIDAE : — *Porphyros edwardii*.

ANATIDAE: — 1) *Anas boschas*, wild duck; 2) *Querquedula circia*, nter teal.

ANSERINAE: *Anser cinereus*, wild goose.

PELECANIDAE: 1) *Pelecanus javanicus*, white-tufted pelican; 2) *P. philippensis*, grey pelican; 3) *Phalacrocorax carbo*, black cormorant; 4) *otus melanogaster*, serpent necked anhinga.

BEE-KEEPING

– Observations on the Formation of Sex in Bees. — I. DEVAUCHELLE, in *L'Apiculteur*, Year LXIII, No. 12, pp 285-288. — II. DECONDRÉ, E., *Ibt.*, pp. 288-290. Paris, Dec., 1919.

Observations disproving the theory according to which the queen-e lays only fertilised eggs, and that it is the working-bees who deter-ne the sex, and confirming the theory of DZIERZON, according to which e queen-bee lays fertilised eggs from which are derived working-bees d females (according to the food given by the working-bees), and un-tilised eggs, from which only males can be derived. The unfertilised gs of humble-bee queens can only give false drones.

I. — Experiments showing that, in a hive deprived of its queen, 4 ma-rnal cells in the breeding cells of males can give males.

If, in this abnormal case of maternal breeding in breeding cells of ones, the eggs had been fertilised, the bees of a colony which was normal ould have infallibly bred young females. And if the attendant bees termine the sex, how, when they had such need of replacing the sup-essed queen, could they only breed drones with eggs laid in big cells?

II. — Experiments showing that it is sufficient, at the end of the summer, soon as the breeding of false drones and the false drones themselves ve ceased to exist in the hive, to suppress suddenly the queen bee of a ve possessing only breeding cells of working-bees, and that the tendant bees can indeed bring up females, but that it will be impossible r them to transform the eggs or the breeding cells of working-bees into lse drones.

2 – Photic Reactions of Honey Bee. — MINNICH, D. E., in *The Journal of Experimental Zoology*, Vol. XXIX, No. 3, pp. 343-425 (Authors' summary p. 342), 17 fig., Bibliography of 50 works. Philadelphia, Pa., Nov. 20, 1919

Light exerts a kinetic influence on the honey bee, and the bee with blackened eye generally loops towards the functional eye. The reactions normal bees and with bees with blackened eyes. when creeping in di-ct or indirect light have been studied. The apparatus used to fur-sh non-direct light consisted of an electric lamp surrounded by a reen inside a white walled cylindrical chamber. Two intensities of umination were employed; 24 m. c. and 957 m. c. Drawings were made the deflective movements of each of the bees studied, determining the verage number of degrees turned for each loop or series of loops in the me intensity of light. By comparing the four first pairs of determina-ons thus obtained, from each of the 52 bees under consideration, it was und that in 81 % of the cases, the bees turned more toward the func-onal eye in an illumination of 957 m. c. than in one of 24 m. c. There is,

then, a direct relation between the intensity of uniform light stimulus (the type furnished by the apparatus) and the tendency to turn towards the functional eye.

The orientation stimulation is really of a continuous nature, and as the process involved in circular movements is identical with that involved in normal orientation, the continuous action of light must be the effective factor in the photic orientation of the normal bee.

SERICULTURE

353 – **Progress of Sericulture in Indo-China** (1). — CABANES, R., in *Bulletin économique de l' Indochina*, Year XX, New series, pp. 782-784 + 5 graphs. Hanoï-Haïphong, Sept.-Oct., 1919.

The author gives a detailed table, accompanied by 5 diagrams, setting forth, for the quinquennal period 1909-1913 and for the years 1914-1915-1916-1917-1918 :—

1) The areas cultivated under mulberry-trees.
2) The quantities of silk-worm eggs set to incubate.
3) The production of fresh cocoons.
4) The production of raw silk.
5) The production of silk materials, waste, silk floss, etc., in Tonkin, Annam, Cambodia, Cochin-China, Laos and in the whole of Indo-China.

The following are some significant figures from this table :—

In Indo-China, the areas cultivated under mulberry-trees have increased from an average of 9610 hectares, during the period 1909-1913 to 13097 hectares, in 1918. The increase was constant and regular. The areas were, and are, greatest in Cambodia, having increased from 6000 hectares in 1909-1913 to 7000 hectares in 1918, that is, from about $^3/_5$ of the total for Indo-China in 1909-1913 to about $^1/_2$ the total in 1918.

For Indo-China, taken as a whole, the quantities of eggs put to incubate have increased, in a regularly progressive manner, from 2961 kg. in 1909-1913 to 4830 kg. in 1918.

Futhermore, the production of fresh cocoons has increased continuously from 4 121 000 kg. in 1909-1913 to 7 286 000 kg. in 1918.

The production of raw silk has increased, in the same way, from 165 840 kg. in 1909-1913 to 291 440 kg. in 1918.

Lastly the production of silk materials, waste, silk floss, etc., has increased progressively and regularly from 206 050 kg. in 1909-1913 to 364 300 kg. in 1918.

While the areas cultivated under mulberry-trees have always been greater in Cambodia (2), the increase in the 4 products quoted below, was not so marked in this country as in Annam and Tonkin, and the two latter have surpassed Cambodia in this respect. Tonkin has become, since 1916, the principal producer in Indo-China.

(1) See *R.*, Nov., 1918, No. 1264 and Oct.-Dec., 1919, No. 1212. (*Ed.*)

(2) On the intensification of sericulture in Cambodia, see *R.*, June 1918, No. 676. (*Ed.*).

In 1918, the 4 products quoted were, in kg. :—

	Tonkin	Annam	Cambodia	Cochin-China	Laos
ggs	16 800	12 600	12 500	5 100	1 300
esh cocoons	2 940 000	1 800 000	1 600 000	751 000	195 000
aw silk	117 600	72 000	64 000	30 040	7 800
lk materials	147 000	90 000	80 000	37 550	9 750

FARM ENGINEERING

AGRICULTURAL MACHINERY AND IMPLEMENTS

54 – **The French Power-Farming Trial Week in Autumn, 1919.** — I. COUPAN, G., in *La vie agricole et rurale*, Year IX, No. 45, pp. 321-334. Paris, Nov. 8, 1919. — II. *Ibid.*, 349-356 (1).

I. — The autumn trial week of power-farming was held on the Sen- s (Oise) plain from Sept. 29 to Oct. 5, 1919, but the exhibition and the ublic demonstrations did not begin till October 1. The three previous ays were devoted to eliminating trials. Without exaggeration, the whole anifestation was brilliantly successful.

An idea can be formed of the power-farming movement that took place in rance during the summer by comparing the number of firms and machines hat entered and took part in the Saint Germain (2) and Senlis trials :—

Demonstrations	French makes	Imported from : —			
		United States	United Kingdom	Czecho-Slovakia	Total
aint Germain	19	17	1	—	18
enlis	27	33	1	2	36
ncrease at Senli	8	16	0	2	18
ncrease per cent.	42 %				100 %

France has obviously made considerable progress.

The constant increase in the number of machines, or types of machines, s desirable up to a certain point, but, as far as the trials are concerned, t is counterbalanced by the excessive area required. Obviously, it will e needful to work the machines in public for a few more years, and, as he machines are useless unless they can furnish sufficient work in a given ime, the plots allotted to the exhibitors can never be too big, no matter ow short the trial. The size of the exhibition would then be out of all

(1) This number is completely devroted to power-farming ; other articles of agricul- ural interest in it will be dealt with in the *Review* for April. (*Ed.*)

(2) For the spring power-farming week, held at St. Germain (Seine et Oise) in 1919, ee *R.*, Oct.-Dec., 1919, No. 1222, § I and II. (*Ed.*)

proportion, whether for the number of days over which the demonstrations would be spread or for the time that farmers could devote to it.

As the machines shown at Saint Germain have ready been described in sufficient detail, only those shown for the first time at Senlis or those that have undergone interesting modifications will here be described.

A. — Direct tractors with independent implements.

(1) *Tractors with non-propelling steering wheels.* — These are always the commonest, but the heavy pre-war type, still favoured to a certain extent in North America, has disappeared, not being suited to French conditions. The author describes several :—

Two Rumely-oil-pull tractors, starting on petrol and running on paraffin. The most powerful one has a horizontal twin-cylinder engine, with 178 mm. bore, 25 mm. stroke, and developing 30 H.P. at 530 revs.; two rear steering wheels (diameter = 1.42 m. ; breadth = 0.46 m.); two forward speeds of 3.4 and 4.5 km., and a reverse of 4.2 km. Weight 4362 kg.

The other model has a twin-cylinder horizontal engine of 151 × 203 mm., developing 20 H. P. at 560 revs. Same general arrangement ; driving wheels of 1.30 m. diameter and 0.31 m. breadth ; two forward speeds (3.4 and 5.25 km. per hour) and a reverse (4.2 km). Weight, 3592 kg. In both machines, the engines are oil-cooled.

The 25 H. P. John Deere tractor, with twin-cylinder, horizontal engine running at 400 to 750 revs. per minute. Runs on paraffin and petrol. Bolster-bolt steering axle 1.30 m. in diameter, and with a 30 cm. rim, driven by a small pinion meshing with a large ring fixed inside the rim ; two forward speeds (3.5 and 5 km.) and a reverse. Weight, 2700 kg.

The following tractors have a 4-cylinder vertical engine :—

T. A. F. tractor (Société des tracteurs agricoles français) with a Ballot engine of about 20 H. P. (90 × 150) ; the steering wheels, placed in front, are 1 m. in diameter, with 0.15 m. rims ; the driving wheels are 1.40 m. in diameter and 0.35 m. broad, with strakes or land-grips (flanged for road work and angle irons on a conical rim) that can be adjusted at will. Forward speeds of 4 and 6 km. Weight, 1800 kg.

The Junior type of Nilson tractor, with a 108 × 146 engine, developing 30 H. P. at 900 revs. and 36 H. P. at 1200 revs. Runs on petrol or paraffin. Speed regulator. Cooling by a cellular radiator made of a special metal stated to prevent deposition of tartar. Steering axle pivoting around a horizontal axis ; control by a lever of the touring-car type. Wheels 0,80 m. in diameter and 0,15 m. wide. The power transmission is of interest. It comprises a transverse shaft, driven by chain and pinions enclosed in a gear-case ; the transmission rings are attached to the shaft by means of springs which take up shocks or strain due to slipping the gears in too smartly. This shaft takes : (*a*) between the girders a wheel 1.26 m. in diameter and 0.45 m. broad ; (*b*) on each side outside the girders, a wheel 1.26 m. in diameter and 0.17 m. broad. These

wo lateral wheels can be removed ; when on the machine they are equi-alent, as supporting surface, to a drum 0,79 m. broad, but, as the wheels re provided with special rachets, turning is easier because the central wheel s pulled on at the same speed as the faster-moving lateral wheel. If he lateral wheels are removed the differential is blocked. Unlike most nachines, the tractive effort is not applied to the frame or axle, but to n axle placed quite above the frame. This axle is connected to the plough by a jointed frame and to the chassis by braces fixed near the engine. The result is that, up to a limit corresponding to an effort greater than hat of which the engine is capable (a limit when the tractor would tip orwards), the driving wheels grip the soil with greater force the greater the resistance.

There are other interesting points in this tractor, particularly the susr pension of the radiator. The forward speeds are 3 and 4 km. per hou when ploughing, and 6 to 8 km. on the road. The weight is 2000 kg. with the 3 wheels and 1750 kg. with the median wheel alone.

The SANDUSKI tractor, of American origin, has a 108 × 133 mm. engine, running at 1000 revolutions and developing 25 H. P. It runs on paraffin or petrol and has an air filter. The steering axle oscillates and the control is of the touring-car type. Rear wheels broad and high, driven by an endless screw system. Weight, 2000 kg.

The SEXTON tractor runs on paraffin ; it has a 102 × 152 mm. engine, running normally at 1000 revs. and can develop 30 H. P. ; the two driving wheels, 1.24 m. in diameter and 0.30 m. broad, are furnished with T irons that are easily removed or put on ; the two steering wheels are 0.91 m. in diameter and 0.13 broad at the rims, and are mounted on an oscillating axle and furnished with a control of the touring-car type. Forward speeds of 2.8 and 4.5 km. per hour and a reverse of 2 km. Weight, 2268 kg.

The type 702 F. I. A. T. tractor has a four-cylinder, 105 × 180 engine, running at 800-1000 revs., and normally developing 25 H. P., it runs on paraffin and has a speed regulator. The general arrangement is similar to that of the FORDSON and AUSTIN tractors, i. e., the usual cut-down frame is suppressed and all the necessary connections are established by the different casings which are assembled by bolts.

This casing-frame is attached in front to the steering axle by a single transverse spring, fastened to the axle by two side-pieces, so that the steering can take up any position ; control of the touring-car type ; wheels 0.82 m. in diameter, with 0.125 m. rims. The driving shaft, on the endless screw system, acts on wheels 1.30 m. in diameter and 0.30 m. broad, to which angle-irons can be fitted. Three forward speeds (3 km. 4.5 km., and 6.5 km.) and a reverse (3.75 km.). The pulley is 32 cm. in diameter, with a 17 cm. rim, giving between 100 and 750 revolutions a minute when engaged with the forward speed and between 135 and 400 revolutions when engaged with the reverse. Maximum tractive efforts :— 2500 kg. on 1st speed, 1700 kg. on 2nd, and 1150 on the 3rd speed. Turning radius, 3.10 m. Weight, 2600 kg.

The Compagnie Internationale des machines agricoles exhibited, as well as the well-known Titan and Mogul tractors, the 8-16 H. P. International tractor. The 4-cylinder engine is of 101 mm. bore and 127 mm. stroke, and has a strong brace, so that two bearings are sufficient to support it ; cylinders fitted with cast-iron sleeves, bored and turned, easily replaceable in case of wear or cracking ; fuel is paraffin or petrol. Steering wheels 81 cm. in diameter and 10 cm. broad ; driving wheels 1 m. in diameter and 30 cm. broad, driven through a differential and two chains; 3 forward speeds (3. 4, and 6 km.) and a reverse. Weight, 1500 kg.

Among other machines are :— The Gaulois tractor, which shows a few changes in detail compared with the Galloway ; the La Crosse tractor of MM. Gaston, Williams, and Wigmore (Paris), of 25 H. P. and a single wide driving wheel; the Ceres tractor of the Société des tracteurs agricoles Cérès (Paris) ; etc.

Amongst the tractors for small farms and vineyards was the A. Citroën tractor (Paris) (1). The engine is cylinder, cast in a single piece, of 65 bore, 100 stroke, giving 12 H. P. at 1600 revs. This small and compact tractor (length 2.50 m., breadth 0.86 m.) has a steering axle bearing solid sheet-iron wheels 0.55 m. in diameter and 2 driving wheels 0,90 m. in diameter fitted with strakes ; 2 forward speeds (3.5 and 4.8 km.) and a reverse (3 km.). Weight, 800 kg.

The Chapron tractor (Puteaux) (2) is also for small farms and vineyards. The 4-cylinder engine (75 × 130) is kept down to 1200 revolutions by a governor. Total length 2.40 m. ; total breadth 90 cm., base area 1.40 m. Steerings by two coupled wheels of 62 cm. diameter the distance between which can be regulated and which turn around a vertical axis.

The driving wheels, fitted with fixed strakes, are 1.10 m. in diameter and 10 cm., wide, and can be widened to 20 or 40 cm. by adding gripping bands ; 3 forward speeds (2.1, 3.4, and 5 km.) and a reverse. The transmission is fitted with a device for blocking the differential, so that the machine can turn in a radius of 1.40 m. In addition, the engine is placed very low to prevent the machine from turning over on slopes. Weight 1250 kg.

The Abeille tractor of the Globe concern (Paris) is unusual. Intended for small farms and vineyards, its frame is supported by a single chain track 81 cm. long and 30 cm. wide ; the 4-cylinder engine (80 × 115) is watercooled. The whole is supported and steered by two wheels placed behind the engine frame fitted with cutting rings and connected by a triangular conical frame to a pivot on the top of the rear of the frame. The fly-wheel acts on this articulation by a chain wheel. This 12 H. P. tractor weighs 1400 kg. and turns in a radius of 1.50 metres.

(2) *" Total grip " tractors.* — These include chain-track tractors and those with 4 driving wheels.

(1) and (2) See *R.*, June, 1919, nº 758; where a Citroën tractor is described and figured and the Chapron tractor mentioned. (*Ed.*)

The PEUGEOT machine is worthy of note among the chain-track machines. Fig. 1 shows this machine with the lateral guard plate lifted, so that the chain track can be seen. The 4-cylinder engine (100 × 150 mm.) develops 19 H. P. The transmission, simplified as far as possible, actuates 2 pinions in the rear which drive chains. The chain track, of a special

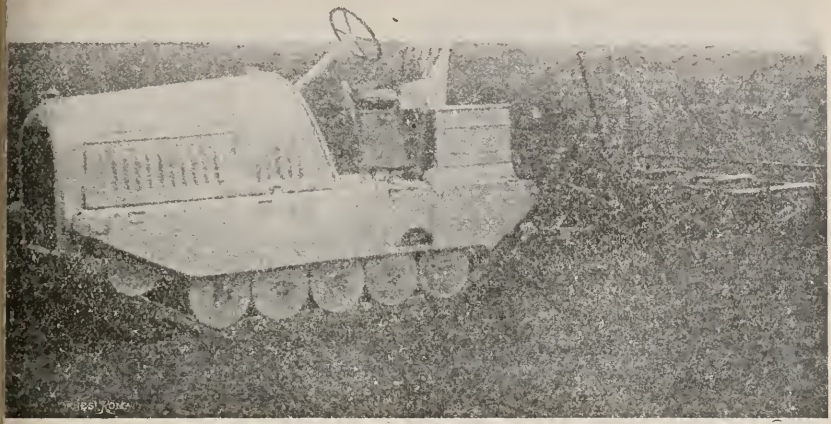

Fig. 1. — PEUGEOT chain-track tractor.

type, has non-jointed shoes with short axes ; they are guided in front by a pulley and, lower down, by 5 rollers. The frame is also unusual in that it is mounted on two pairs of guides, each placed in a plane perpendicular to the plane of the other. In this way, the engine and transmission are rendered independent of the positions occupied by the chain tracks.

The tractor weighs 2850 kg.

The Italian PAVESI tractor, known as the " Agrophile " is a very curious machine that really consists of two separate carriages, whose wheels are controlled and united or separated as required. The forecarriage, however, comprises the engine, steering, gear-box, etc.

Each carriage consists of a frame ending on one side in an arched rod shaped like a convex arc of a circle and fitted on the under part with a rack. The bearing wheels are 1.20 m. in diameter, with rims 25 cm. wide ; they are mounted on fixed, rigid axles and driven through a differential and chains.

The chief carriage has a horizontal and opposed 2-cylinder engine parallel to the axle ; it has a 130 mm. bore, a 170 mm. stroke, and develops 25 H. P. at 900 revs. There are 2 forward speeds (3 and 6 km., the latter for running on the road) and a reverse, all enclosed with the differential,

and the drive for the second carriage is a casing continuous with that of the engine. The second carriage has only a differential, also cased in.

To assemble the two carriages, they are joined by the arched parts, which thus have a similar function to that of the buffers on tramway trailers and they are fixed by means of a jointed cardan tie-rod on the two axles ; this tie-rod bears, at its centre, a loose pulley which engages with the two racks placed below the curved members. Another shaft with

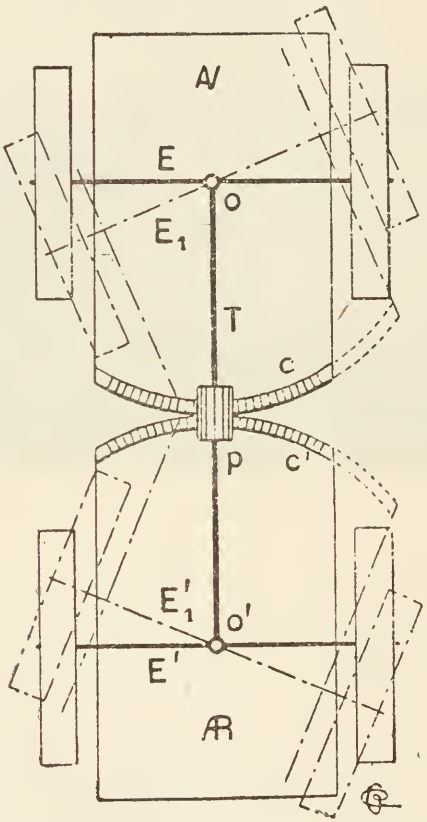

Fig. 2. — Steering of the PAVESI tractor.

a double cardan goes from the gear-box of the main carriage and controls the differential of the second carriage. The four wheels are all driving as well as steering wheels, or, more accurately speaking, the two axles steer. In fact, if the driver moves the steering wheel, the axle *E* of the main carriage *AV* (Fig.) turns obliquely, e. g., to the left to *E*1, which moves the curved members to the right ; the rack *c* carries the loose pinion *p* of the tie-rod *T*, but this, on turning, forces the rack *c'* and the

curved member of the second carriage *AR* to move to the right and, consequently, forces the axle *E'* of that carriage to move to the right and take up the position *E'*1. The two axles are then in such a position that a very short radius is required for turning the tractor; in fact, the external turning radius is 3.25 m.

When it is observed that the articulations *o* and *o'* of the tie-rod *T* on the two axles are cardans, it will be seen that the two carriages can take up any position in a transverse direction compared with each other. Thus the tractor can travel on the most uneven ground, as its two driving axles allow it to overcome obstacles more easily in spite of an average power and relatively light weight (2350 kg.). The usual compensation for complicated transmissions requires total adherence, and the complication is partly avoided in this case by the use of driving and steering *axles* instead of driving and steering *wheels*.

For light work, the driving carriage can be used alone by attaching it to a cart as a fore-carriage; but with both carriages the high tractive effort obtained is sufficient to tow several vehicles.

B. — Direct tractors forming one with the implement.

The firm of the Charrue automobile Henri Amiot (Paris) exhibited the "Gerbe d'or" machine which is of the type of motor plough with a tipping gang, the experimental model of which was described before the war. This principle has been retained:— A double-brabant 3-furrow plough, hooked to the engine frame, lifted with a block, and tipped by means of mechanism driven by the engine.

The 25-30 H. P. Aster 4-cylinder engine has a carburettor that enables heavy oil to be used. Weight, including ploughs, 2600 kg. Normal speeds 4 km. when ploughing and 6 km. when harvesting.

There was also the small Beeman machine, shown by the Société traction et matériel agraires, with a 6 H. P. engine and 2 steering stilts, and which can be used for ploughing on a small scale or for weeding market-garden crops.

The Avery motor-cultivator (Fig. 3) can also be used as a hoe. The working members, of various shapes, are attached to the ends of levers articulated with a cross-bar slung from the frame and can be regulated and lifted by means of levers. The motor frame carries a 4-cylinder 76 × 100 engine, running at 1200 revolutions and thus developing some 10 H. P. Steering is done by a single 70 cm. wheel provided with a central flange, mounted chair-castor fashion on a vertical axis controlled from the driver's seat, which is placed behind the working members. The driving wheels, 1.05 m. in diameter and 15 cm. broad, are chain driven; when turning, 2 pedals block one side or the other of the differential and enable the machine to pivot round the blocked wheel in a small radius; 3 forward speeds (1.6, 2.5, and 4.9 km.) and a reverse (1.6 km.). Weight, 1450 kg. Runs on petrol, benzol, or alcohol.

C. — Single-axle motor-ploughs.

The prototype of these machines is the German Stock plough (described in this *R.*, Nov., 1914, No. 1039) which is designed to furnish a large amount of work on a small consumption. These machines usually consist of a frame shaped like an elongated triangle, supported by an axle which may be in one piece, placed near the base of the triangle ; at the apex there is a wheel provided with a cutting rim which acts as the " sole " and also serves to guide the machine. The engine, always powerful, is placed near the base in front of the axle. The plough bodies, of varying number, are fixed on one of the sides of the triangle, between the axle and the guiding

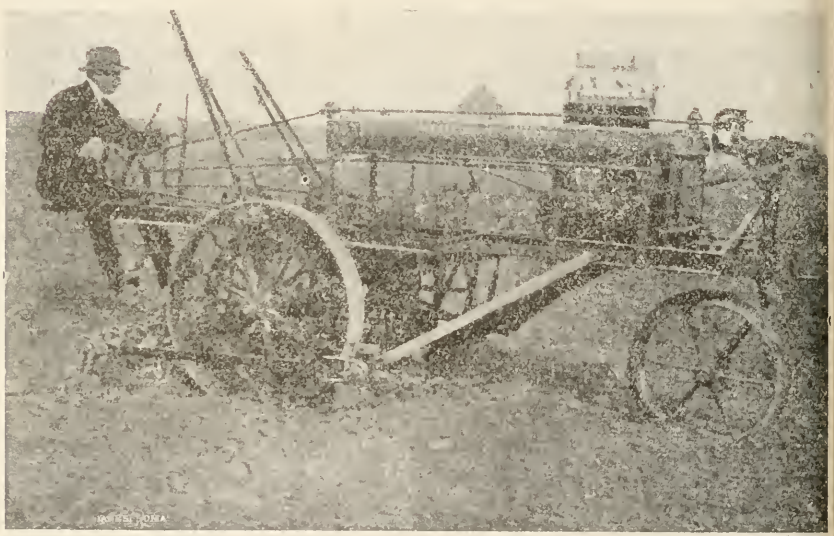

Fig. 3. — Avery-Pilter motor-cultivator.

" sole ". As the latter is not placed in the median plane of the axle, the plough turns more easily one way than the other.

It is advisable that as much of the total weight as possible should be borne by the driving axle, which is always fitted with wheels of large diameter, and this can be done by approximately balancing the weight of the frame and the ploughs by the position of the engine and its accessories. The weight of the two parts must not be balanced exactly, although the reaction of the engine is strongly felt when moving forward, for if the reaction is felt in the inverse movement, it would lift up the gang and cause the machine to tip up. The makers have arranged matters so that normally nothing need be feared from tipping which is actually made use of, as will be seen from the description of the following machines.

The Praga plough (Fig. 4,), made by the Première fabrique Czecho-Morave de Machines (Prague), weighs 4000 kg. and measures 7.20 m. long, 2.25 m. broad, and 2.45 m. high. The two large wheels and the heel support a flat frame, in the front of which is a 4-cylinder, 105 × 106 mm. engine, developing 40 H. P. at 1050 revolutions; the magneto has an independent drive; benzol or petrol can be used as fuel. The plough bodies, 4 or 5 in number, according to the working depth and the resistance of the soil, are fixed on a frame which is joined to the main frame by forks and gudgeons and an endless screw drive, controlled by a hand lever, connects the engine to the device for lifting and earthing the plough bodies; adjustable pieces enable the desired depth to be obtained and kept uniform. As will be seen from the Figure, the driver has a comfortable

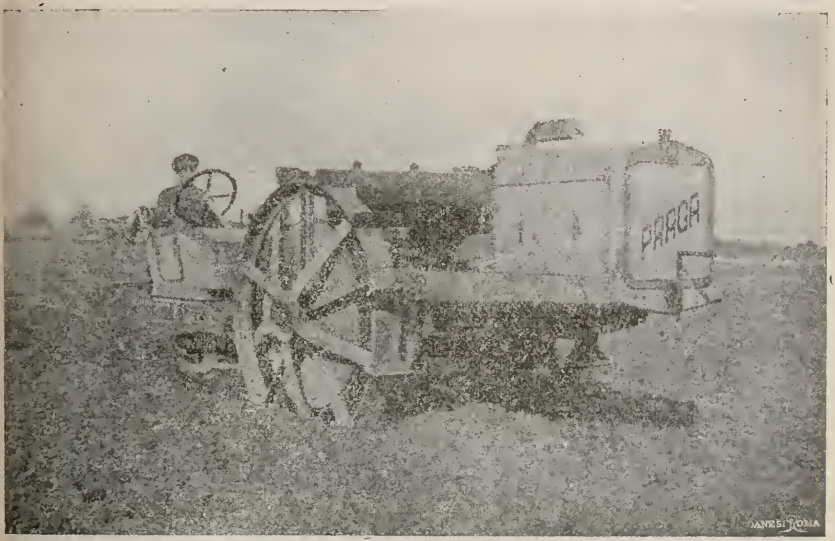

Fig. 4. — « Praga » motor-plough.

cabin, with a movable hood for bad weather. There are two speeds, 3.5 and 4.5 km. per hour. This plough can work 4 or 5 hectares in a 10-hour day, at a working depth of 20-25 cm., and with a consumption of 18 to 20 kg. of petrol per hectare.

The Excelsior plough, made by the Fabrique de charrues automobiles de Mlada-Boleslav (Czecho-Slovakia), has a single frame, articulated below the two large wheels (1.76 m. in diameter). In the rear, there is a strong "heel", provided with a cutting ring for guidance. The 4-cylinder, 100 × 150 mm. engine develops 35-40 H. P. and drives, through the differential, wheels displaced in height by 20 cm. The forward speeds are 2.4, 3.4, and 4.5 km. per hour and the reverse gives 2.4 and 4.5 km. The gripping strakes are rivetted on the rims; but rims are provided which

can be put on when the tractor runs on the road. The lift system is worked from the reversing gear ; as the support of the heel can slip into a slide, the massive heel only prevents tipping when the gang is lifted ; the support is then at the end of the slide and an automatic pin holds it in that position, and it is then ready for turning. Earthing is brought about by a free fall topped by a wedge suitably placed in special holes, enabling the desired depth to be obtained, no special handling being required while working. The plough has from 3 to 6 bodies and can work at a depth of 40 cm. with three bodies. The total dimensions are :— Length 6.20 m., breadth 2.40 m. The weight is about 5000 kg. It can plough from

Fig. 5. — The new cultivator E. Bauche & Cie.

4 to 6 hectares per 10-hour day, according to the soil, with a consumptio of about 32 litres per hectare when ploughing at a depth of 38 cm. Tw French makers also make use of the reaction of the engine to handle th plough at the end of the furrow, but these machines are so designed as t allow of ploughing without ridges.

M. L. Dubois (Asnières, Seine); makes, under the name of " Poly culteur ", a fore-carriage tractor (with two wheels) that can be adapte to different culture or harvesting implements, even to farm carts. Th polyculteur was working at Senlis with a 3-furrow double brabant. Th 4-cylinder, 90 × 150 mm. engine develops 20-25 H. P. between 1000 an 1200 revolutions ; it is placed in front of the axle and a roller-drag su

orts the fore-carriage when not attached to an implement. The wheels, which drive and steer at the same time, are fitted with a special kind of tipping device, which projects through the rims and is kept in action or projecting, by bolts each acting on two consecutive paddles. The frame terminates in front in an " écamoussure " bearing 4 horizontal superimposed bearings, one of which will receive the gudgeon which must be attached to the front of any implement which the polyculteur will haul. As regards the 3-furrow brabant plough, the weight of the two sets of 3 bodies must be quite the same, so that the plough can turn equally easily in either direction ; the gudgeon, however, is not in the same plane as that of the centre of gravity and is really between the latter and the stanchions of the front bodies. Thus, when the driver reverses at the headland, causing tipping and freeing the brabant, meanwhile turning the wheel towards the land to be ploughed, the bodies turn over to the side of the stanchions ; turning with the reverse produces a couple which accentuates the pivoting movement, and when the forward speed is geared up, the turn finishes and the plough slips into place itself as soon as the point of the first sock enters the ground. This is an unusual device. M. Dubois has suggested the adaptation of a windlass for cable-ploughing on the shuttle system, with a two-way plough hauled by two similar machines.

M. E. Lefebvre (Rouen, Seine-Inférieure) showed the Normania 3-furrow tipping plough, whose wheels, 1.40 m. in diameter and displaced in height by 20 cm., receive the direct drive of a 20 H. P., 4-cylinder Ballot engine ; the reaction of the engine forces the plough bodies on to their work ; on reversing, the plough is tipped over. There is only one speed, with a device for reversing the drive. The plough bodies can be regulated separately, so that they trip in properly. The machine, which weighs 2700 kg., can plough, using 3 bodies on each side, from 2 to 2.5 hectares a day, according to the resistance of the soil.

D. — Machines with moving working members.

MM. Eugène Bauche & Cie. (Chesnay, Seine-et-Oise) have made an important modification in their small motor cultivator ; the engine is now watercooled and provided with a radiator, so that the engine (Fig. 5) can run full out without fear of over-heating.

MM. Pétard & Préjean (Aubervilliers, Seine) have produced a " mixed " machine, called " cultivateur rotatif et vignoculteur " (Fig. 6) which can be driven by an injured person. A 2-wheeled axle, fitted with shafts for a horse and a driver's seat, carries a 4-8 H. P. engine which drives a horizontal shaft, whose height can be adjusted and which is provided with numerous long, curved tines. The speeds are changed by means of a handle and the tine are lifted by means of a crank, so that a man with injured legs could drive the machine ; the handle or crank can be replaced by a pedal to enable a one-armed man to use the machine. The machine is illustrated in Figure 6.

E. — Ploughing sets.

MM. J. Fillet & Cie. (Bordeaux) make small windlasses mounted on 3-wheeled frames, with drums that take 215 m. of cable 6 mm. in diameter, and driven by H. P. engines. The cable can be wound up at 3 speeds :— 60 90 and 110 m. per minute, with the engine running at full speed (1400 revolutions), the intermediate speeds being obtained by reducing the engine

Fig. 6 — The Pétard & Préjean rotary cultivator.

Two similar windlass-waggons are used, to draw a tipping plough shuttle fashion. The windlasses are kept in position by an anchor spade attached to the front of the frame and also used to make to cable wind evenly. The engine is either a 4-cylinder Ballot or Panhard, or a 10 kilowatt electromotor of a type suitable for the current to be used.

F. — Various accessories.

The author concludes his article by describing a *dynamometer* specially made by M. G. Desprez (Neuilly-sur-Seine) for use in power farming: It consists of a flat spring, rolled up snail-wise and enclosed in a jointed, deformable frame. The tractive effort reduces the height of the frame,

mpressing the spring, and the movement is transmitted through a ck and a toothed pinion to a needle moving over a graduated dial ; a cond. needle, loose on its axis and kept rubbing by a small spring, shows e maximum effort obtained. This compact and light dynamometer as tried by the author on a PEUGEOT chaintrack tractor and on a Feltz wing tractor ; the graduations are easily read and, although the limit r which the spring was made (1000 kg.) was more than passed, yet further adings taken, agreed with previous ones and the needle came back exactly zero. The author thinks that a simple and inexpensive dynamometer the necessary complement of any power farming machines on which can be used for, when it is possible to ascertain at any moment the ork required of a tractor, it will avoid overloading and many mistakes.

II. — The Editorial staff of the *Vie agricole et rurale* adds informat on supplied by certain makers regarding the machines they exhibited.

(1) PAVESI P4 *" Agrophile " tractor.* — Described above. Besides s use for ploughing, it can tow harvesters, drills, etc., and can do trans ort work on the road, replace locomotives, and drive threshers, presses, umps, etc. from a pulley. Costs little in labour, as one man is sufficient.

(2) PAVESI P4 *lorry-tractor.* — With 4-driving wheels ; it is a real *olonial lorry*, which may replace the horse, camel, and elephant in those egions still unprovided with roads, and thus bring about considerable aving compared with the means of locomotion now in use. In fact, can run fully loaded on roadless deserts and steppes, undisturbed by neven land, steep slopes and the narrowest curves. It can draw a road rain (Fig. 7).

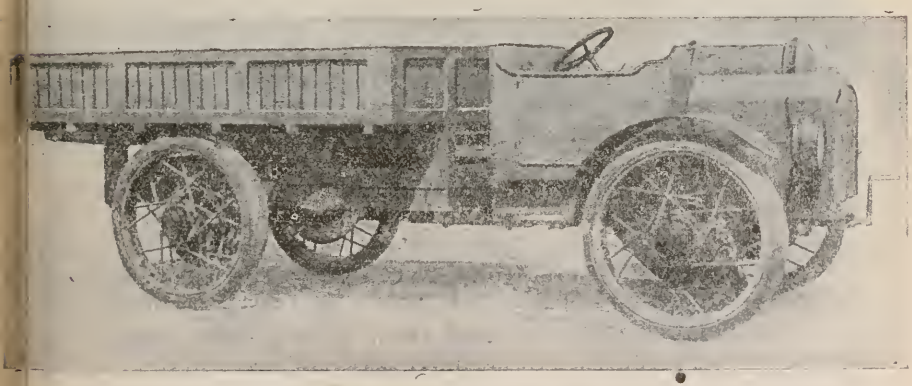

Fig. 7. — PAVESI lorry-tractor.

(3) PAVESI *trailers.* — The SOCIÉTÉ AUXILIAIRE AGRICOLE (Paris), which exhibited the Italian PAVESI tractor, makes trailers for this lorry ractor :— (*a*) 5000 kg. trailer ; (*b*) 3000 kg. trailer ; (*c*) agricultural railers (one model with steel springs and another without springs).

(4) *Agro fore-carriage tractor.* — This for-carriage tractor, which had already been shown at the spring trial held at Saint Germain (1), reappeared at Senlis with important additions and modifications. A reverse has been added, and the road speed diminished so as to obtain direct traction at a speed of 4.9 km. per hour. Soil-grip is obtained by fitting each of the wheels with two half-rings provided with special strake that enable the machine to run smoothly on the road, and do away with the lateral twists that strain the axle. The small breadth of the machine (96 cm.) allows it to be used among vines. It can haul a cultivator, harrow, mower, etc.

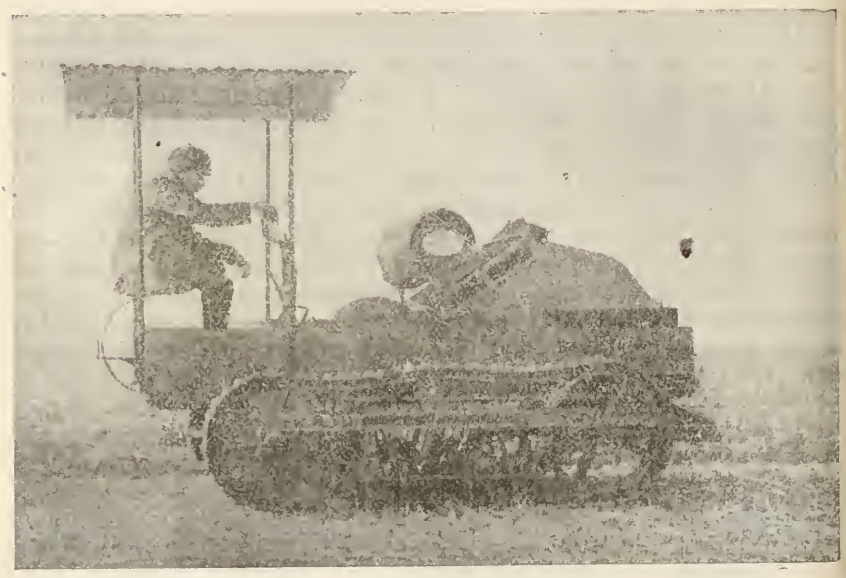

Fig. 8. — RENAULT tractor.

(5) *The* 16 *H. P. Happy Farmer tractor.* — The " Taureau " tractor of the Agricultural Co.

(6) RENAULT *farm tractor.* — This tractor (Fig. 8), which attracted much attention at Saint-Germain (1), has obtained a fresh success by ploughing 2 hectares 18 cm. deep with a 4 furrow plough in 5 ½ hours.

(7) *Tank Neverslip tractor.* — The machine shown at St. Germain was of 12-20 H. P., but that shown at Senlis was of 18-30 H. P. A chain-track tractor, combining the principles of the motor-car and the railway.

---

(1) and (2) See *R.*, Oct.-Dec., 1919, nº 1222. (*Ed.*).

(8) TOURAND-LATIL *motor plough* (1). — Motor plough mounted on 4 wheels, weighing (with the plough) 3200 kg. ; 35 H. P. engine ; two forward speeds (3.5 and 5.5. km.) and a reverse (with a single loose pinion). The plough is lifted at the end of the furrow by a special shaft driven from the engine.

(9) *" Le Gaulois " tractor and plough.* — See Part I.

(10) BAUCHE *motor cultivatotor.* — See Part I.

(11) XAVIER CHARMES *pulveriser* (2).

Fig. 9. — « Messidor » plough hauted by a TOURAND-LATIL tractor.

(12) BAJAC *windlass-tractor.* — Well known. Now fitted with carburettor that enables either petrol or paraffin to be used as fuel.

(13) *Messidor reversible plough.* — The only machine that can plough without ridges when towed by any tractor. The driver of the tractor suffices to attend to the whole machine. All the advantages of the brabant plough are duplicated and amplified in this machine. Two-furrow and 3-furrow Messidor ploughs are made by R. M. PÉTARD.

(14) *T. P. rotary cultivator and vine cultivator.* — See Part I.

RURAL ECONOMICS

55 – **The Influence of Good Farm Organisation on Costs of Production.** — HANDSCHIN, W. F. (College of Agriculture, Urbana, Illinois), in the *Journal of Farm Economics*, Vol. I, No. 3, pp. 102-109. Lancaster, Pa., Oct., 1919.

It is not easy to separate definitely the influence of good farm organisation from the influence of good operations and other factors ; it is never-

theless possible to show how good organisation affects production, and to measure with reasonable accuracy its influence on costs. With this purpose in view farm organisation can be studied from the standpoint of three principal divisions : — 1) financial or economic organisation ; 2) physical organisation ; 3) productive organisation.

The financial or economic organisation of a farming business is concerned principally with the problem of determining the minimum size of the business that is well adapted to the type of farming to be carried on, and of working out the most profitable distribution of the investment in various items such as land, buildings, machinery and tools, horses and other livestock. It is evident that, if production is to be carried on most effectively, the various items of investment must be utilised to the fullest extent, consistent with the maximum returns for the farm business as a whole. The influence on the cost of production is very marked.

The investment in farm buildings in Illinois, exclusive of the farmer's residence, which is a personal item, often varies from $10 to $15 per acre for the same general types of farming carried on under similar conditions. Apparently these classes of farmers have adequate shelter for stock. Assuming a carrying charge of 15 % per annum for interest, depreciation, upkeep, taxes, and insurance, the total carrying charge per acre varies from $1.50 to $3.75 a year. That is, the difference in carrying charge, or the cost of production per acre, due to this one item alone is $2.25 per acre per year.

In the same way, in the case of machinery, exclusive of tractors, the carrying cost ranges from $5 to $10 per acre. Assuming a carrying cost ranging from 20 to 25 % (including interest, shelter, taxes, upkeep and depreciation), these differences in the investment of machinery per acre would mean a difference in carrying charge of from $1.00 to $1.25.

If the physical organisation of the farm is studied from the standpoint of its influence on production and costs, it is found to have a notable bearing on the problem. In working out the plan for the best physical organisation of a farm, the plan can be divided logically into two parts : — *a*) the organisation of the farm as a whole, including the location of the farmstead, and the general laying out of the field system ; *b*) the more detailed planning of the location and arrangement of yards, paddocks, lanes and buildings. In the first case, the importance of reducing to the minimum the distance between the farmstead and the fields should be remembered ; but the advantage of having the farmstead within easy reach of the public road should not be forgotten.

In planning the field systems for the major rotation : — 1) There should be as many fields of nearly equal size as possible, as there are years in the rotation.

2) Fields should be as large as practicable to save time doing farm work and reduce the cost of fencing.

3) Fields should be rectangular if possible, and about twice as long as they are wide.

Many farms could be improved in this respect. The University

Minnesota reports that in the replanning of a 160 acre farm situated in Missouri the average distance from the farmstead to the fields was reduced from 70 to 24 rods, and the amount of inside fencing was reduced from 892 to 640 rods. Illustrations of this kind could be multiplied indefinitely.

The problem of physical organisation is relatively more important on farms producing livestock where the question of handling livestock with the minimum expenditure of man and horse labour presents opportunities for very important economies. All yards, paddocks, pastures, and lanes should be so laid out as to allow for easy moving of animals from one place to another about the farmstead or between farmstead and farm fields.

The location of barns, stables and feed storage should be so planned as to reduce the man and horse labour required to a minimum. Systematic study of these questions has now been begun; their aim is to diminish the cost of production through good reorganisation.

Important as the economies are which can be effected through the best financial and physical organisation of the farm, it is probable that on a large majority of farms even greater economies can be effected through the more scientific organisation of their productive enterprises.

In the organisation of the crop and animal enterprises with a view to establishing the most profitable and permanent systems of farming, a number of complex and inter-related factors must be taken into consideration owing to their influence on production and costs. The maintenance of the fertility of the soil, the most advantageous marketing of produce, the best utilisation of the man and horse labour used, the insurance against crop failures, price fluctuations, and other unfavourable conditions, these are the problems closely associated with the present system of agriculture, and the solution can only be looked for in a ready combination of these factors.

In the study of costs of production, the expense of maintaining fertility has been almost entirely overlooked. In working out this problem, the growing of leguminous crops offers the most economic source of nitrogen, and the rotation should include the proportion of leguminous crops necessary to maintain or increase nitrogen in the soil, and if the manure is carefully handled, from 60 to 70 % nitrogen, from 75 to 80 % phosphorus, and from 80 to 85 % of the potassium contained in the crops fed can be returned to the soil. In so far as the mineral elements in the soil are limiting factors in crop production, they should be added in such form and in such amounts as will contribute most to the profits of the entire farm business.

In organising the productive enterprises so as to provide the most advantageous market for all products, livestock plays an important part, because it is possible to market advantageously not only the salable portion of the crops grown, but also the unsalable and waste portions. This factor alone eliminates much waste and helps to increase profits, without increasing the cost of producing animals and animal products.

In practically all types of farming in the United States, man and horse

labour make up from 75 to 85 % of the total operating expenses. A good rotation of crops, with two or more kinds of livestock, make possible the most even distribution of labour throughout the year and this has a marked influence on production and costs. The variations found in Illinois in the cost of horse labour are responsible frequently for differences of from $1 to $4 per acre in the production of ordinary crops, such as maize, oats, wheat and hay. It is not easy to say how far these differences are due to good farm organisation or to other factors; but it is plain that they are mainly due to the more efficient organisation of the productive enterprises, i. e., the crop rotations and the systems of animal production followed.

The more even distribution of labour throughout the year, as a result of the better organisation of the crop and animal enterprises, makes it possible to find productive employment at the moment when the demand is greatest, There is, consequently, an increase in price and a better grade of labour can be secured.

By combining the growing of several crops well adapted to the region and marketing them with several classes of livestock, the largest measure of insurance is procured against crop failure, price fluctuations, and other unfavourable conditions. The flexibility obtained in the livestock enterprises by carrying at least one class of animal which can be reduced or increased. is worth noting. Swine, sheep and poultry represent illustrations of flexible animal enterprises, whilst the different classes of dairy cows and beef cows represent the more inflexible forms.

Efficient farming consists mainly in so adjusting the financial, physical and productive organisation of the farm so as to return the maximum profits for the entire business over a series of years. Each enterprise must be studied from the standpoint of its influence on the business as a whole.

356 – **Farm Management Problems in the United States.** — Bilings, G. A., in *Journal of Farm Economics*, Vol. I, No. 1, pp. 3-7. Lancaster, Pa., June, 1919.

The unusual demand for food products and the scarcity of farm labour since the war began, have given rise in the United States to conditions which demand greater concentration of effort on farm management problems. These problems affect the community, the state, and the country as a whole and are in a measure sociological, but since they bear a close relation to production and to the individual farm, the basic unit of production, they are of vital importance to the economic management of the farm.

There has been no period in the history of the United States when economic conditions have changed so rapidly, requiring the most careful thought concerning the organisation of farms of different types to meet present day needs, and the changes which may take place after the war ; the policy of price fixing of farm products and its bearing on profitable production as compared with the fundamental law of supply and demand ; the mobilisation of farm labour to produce the supply of food needed ; and many other important factors have combined to furnish entirely new problems.

The cost of producing milk in large dairy regions and the cost of producing wheat as the basis for fixing the minimum price of wheat to the farmers,

illustrates the kind of information which has more recently been demand ed. The request for such information shows conclusively that the results from the investigation of farm management problems by state and federal departments should be tabulated, summarised and held in readiness for such requests. Moreover this information should be put into such shape that opportunities may be given to the farmer to obtain suggestions for adjusting his system of farming to meet these changing conditions.

During the last ten years farmers have adjusted their business to meet slight changes in economic conditions. The ratio between food production and the increase in population has been quite constant.

The work in farm management has been therefore mainly to study the organisation of farms and the farm practice in agricultural regions, in order to discover the relationships between farm enterprises and to determine what factors have a direct bearing on net incomes. The influence of such studies should be to induce the farmer, whose farm is not producing profitably, to adopt those practices which will increase his income. This work has had a tendency to raise the average production and take care of the increase in population.

Increasing the Nation's Food Supply. — The situation in relation to the food supply has been not so much economic as nutritional, that is, it has been a question of systems of production to feed the people rather than systems arranged purely for the sake of gain. No more effective work can be continued than the presentation of facts calling attention to the relative value of foods produced on an acre, with suggestions in farm practice that will increase profitably, if possible, those products of greater nutritional value.

Relation of the Labour Supply to Food Production. — In view of the depletion of the country's food supply and the possibility of a continued demand for increased crop production, farm management men should devote special attention to methods of adjusting the farm plan to give maximum production with the greatest efficiency in the use of labour and machinery. The scarcity of skilled labour has been the principal limiting factor in production, and this factor will check the intensity of farming. The use of tractors in ploughing and the preparation of soil for sowing may enable the farmer to get his crops planted at the proper time, though possibily this may not be much of a factor in reducing costs. A saving of a man power will likewise result from using four, six or more horses with larger machinery. Any line of work that will demonstrate how production may be maintained with less manual labour is most important at this time, otherwise there is great danger of land which might be used for wheat or other food crops being seeded down and a more extensive type of farming adopted.

It is essential to have information concerning the amount of labour required for farm operations and its distribution. These data are fundamental in working out cropping systems, particularly in determining when and how much labour is required for each month in the season. It will show in advance what regular labour is necessary and indicate when extra help is needed. If it is impossible to obtain extra help at these times, it may be

possible to introduce some labour-saving machinery or the farmer may co-operate with neighbours in exchange for help. If this difficulty is anticipated and the amount of labour required for different operations is known, the difficulty may be obviated by readjusting the crop acreages and the introduction of supplementary crops, which will maintain a more uniform labour requirement. It is in the solution of problems such as these that farm management men can be most helpful.

The economy in conducting farm operations is also influenced by the location of farm buildings and the shape and arrangement of the fields. The arangement of farm areas, making larger and more uniformiy-sized fields which can be more easily handled in rotation, would simplify the handling of machinery, save much time, and reduce the cost of production. Such work would attract the attention of farmers and be appreciated by them.

Standards Needed in finding Cost of Production. — The importance of adopting, as far as possible, standards in methods and agreements as to the elements in production cost studies, has been demonstrated by the greatly increased interest in this subject due to price fixing. Many agencies have been at work on these studies during the past year and such results as have come to light vary greatly in method of presentation as well as the elements included in determining cost.

Sometimes, overhead or indirect costs are included, and at other times omitted, in spite of the fact that every farm must bear in labour cost alone a burden of indirect expense equal sometimes to one-third of the cost of all the labour performed. These same discrepancies exist as to other elements such as machine cost, supervision, building costs, etc.

Sometimes particular interests affecting the point of view, influence the interpretation of inter-relationships in production cost finding. One group insists that all feedable crops produced and fed should be charged to live stock at cost of production. On the other hand, many writers, including those of the experiment stations and the United States Department of Agriculture, believe that market value at the farm is the only safe practical and correct value to use. The subject of cost production presents greater difficulties in certain aspects than almost any other branch of accounting because of the many interrelations between farm enterprises. For example certain equipment is used in preparing the ground, cultivation and sometimes harvesting of more than one crop. When land is prepared for oats or wheat, the land is also prepared for clover and timothy which follows. Likewise, in some regions, clover and timothy is seeded at the last cultivation of maize Maize, oats and wheat are sometimes combined with live stock production The raising of pure-bred cattle and milk production are very closely related and the costs would be hard to separate were it not for an established rule among farm accountants that in pure-bred stock production milk is a by-product and the cost of feed in animal production is not chargeable to milk.

Importance of Studying Farm Practice. — Crop yields and production per animal are important factors in profitable farming; therefore any practice

that will increase crop yields and production per animal will be not only of economic interest, but will increase the food supply. Experiment station results clearly point out methods for increasing production, but these conclusions may be confined to certain types of soil. Just as important results have been worked out by farmers under much more widely varying conditions, hence, the study of farm practice should be an important field of work.

Farm management surveys may help to analyse economic problems, but the story of how soils have been made productive through systems of rotation with clover, alfalfa, soya beans or other legumes, and the methods practised in the use of cover crops, manure, lime and fertilisers, will help to interpret the figures obtained from surveys. Farm management surveys provide a basis for the analysis of systems of farm organisation and the results from certain operations. Farm practice studies, on the other hand, will show the methods employed and why certain results are obtained. It gives additional information necessary to work out a complete farm plan. There is an unlimited field for work of this sort which will go far towards developing standards for farm operations.

Co-operative Investigations. — Progress in the study of economic problems will develop more rapidly, and the results of investigations will be applied more successfully by the most earnest co-operation between the United States Department of Agriculture and state agricultural institutions ; between the investigator or demonstrator and the farmer.

The state institution is restricted in territory, whilst the federal department can study regions which may include several states.

There is a great amount of data which have been obtained through surveys, and which would make an interesting field of study if these data could be assembled and correlated. Instead of dealing with a few hundred or less, there might be several thousand records, which, when assorted, would give much larger groups and a basis for more accurate conclusions. It would give an opportunity for the study of selected types of farming, the profitableness of different combinations of enterprises. and of many other problems hitherto impossible.

357 – **Important Factors in the Cost of Producing Wheat.** — Boss, Andrew (University Farm, St. Paul Min.), in *Journal of Farm Economics*, Vol. I, No. 3, pp. 85-89. Lancaster, Pa., October, 1919.

For something over two years the importance of wheat production has been emphasised and kept before the world, first by agitation for a guaranteed price for wheat during the war and second by more or less serious attempts to determine the cost of producing wheat.

It is, therefore, important to know the factors of cost in wheat production and to find out how costs can be reduced or eliminated.

The factors of cost in present-time wheat production in the spring wheat growing section of America may be classified in the order of importance as follows : — Labour (man and horse), land, seed, machinery, threshing costs, general expenses and cost of twine. Fertilizer cost or values consumed is

just as legitimately a cost as any of the preceding items, but no one has as yet devised a satisfactory basis for determining what this cost is. No charge is commonly made, therefore, for soil fertility consumed in producing a wheat crop except where commercial fertilisers or manures have been purchased for cash.

Labour costs. — The cost for man and horse labour constitutes the largest item of cost in wheat production. It was found to be 41.4 per cent. of the total cost in Minnesota during the years 1913-1917. With increasing wages for man labour and much higher feed cost for horse labour than prevailed during that period, the labour cost now assumes an even greater proportion of the total. The opportunity for reducing the man labour cost lies in efficient management. The average hours of man labour required in Minnesota were found to be 12.3 and of horse labour 29.9. Some farmers are able to reduce the amount to 10 hours or less of man labour and 25 hours of horse labour, by the use of large implements and effective methods. The cost of producing an acre of wheat would be, therefore, considerably less than the average. The rate paid for man labour is a factor of importance in the aggregate cost of an acre of wheat, but it is little subject to variation during the season. The rate of horse labour, however, may be controlled to a considerable extent by the kinds and amounts of foods fed and especially by the number of hours of labour performed annually per horse.

The land factor. — Land is one of the largest factors in wheat production. Not all land is suited to wheat production. Climate also affects the growth and influences greatly the yield and quality of the wheat and ultimately the cost of producing it. Land that will grow wheat and that is favourably located as to climate is limited and is becoming increasingly more expensive.

It is much more difficult to grow wheat profitably on $ 200 land than on $ 100 land. It has been estimated that to secure the same percentage of profit on investment on $ 100 land as on $ 25 land, a yield more than 4 times as great must be obtained. The charge for the use of land may be computed from one of two bases. It may be charged at rental value where cash rent is paid or the rental value can be otherwise determined. Or the charge may be made up of the items of cost, which are interest of the investment in land, taxes, upkeep of drains, fences and other land improvements. Where the values are affected by proximity to a large city or market with a strong demand for town lots or where values are greatly affected by speculation, as is now the case in the north central area, the rental value is perhaps the safest basis.

In normal times when values fluctuate less widely, the interest on investment basis is quite satisfactory. In determining the interest charge prevailing, prices of land exclusive of buildings should be used and interest figured at the rate at which money may be borrowed on well-secured farm loans.

In cost of production studies in Minnesota (1913-1917), the cost for the use of land was calculated to be $ 4.60 an acre or 28.2 per cent. of the total cost. Land values have since risen and present costs are much larger. There is no way to reduce this cost per acre in wheat production except to

grow wheat on cheaper land. The bushel cost could of course be reduced by increasing the yield, provided the increase can be secured without corresponding increase in other expenses (1).

Seed cost. — The seed cost of wheat is determined by the quality and quantity used and the market value. The seed cost in Minnesota, from 1913 to 1917, was 11.4 % of the total cost of growing an acre of wheat.

Machinery cost. — Machinery plays a large part in wheat production. In fact it is because the wheat crop can be so well handled by machinery that it is so popular with farmers. It is difficult to determine accurately the cost for machinery for a specific crop where so much of the machinery is purchased and used for all crops in common.

The charge for the use of machinery is made up of depreciation, interest on investment, repairs and oils, labour for repairs and care of machinery.

Depreciation may be roughly calculated at 10 per cent. per year though in studies made in Minnesota, the record depreciation over a long period of years was found to be only 7.3 per cent. There is a wide difference in rate of depreciation for different machines and also on different farms.

In order to charge machinery values correctly it is necessary to determine the acre cost of each machine and distribute it to the various crops concerned. The cost for machinery has greatly increased during the past two or three years owing to the increased price of new machines, the increased cost of labour and repairs, and other expenses of maintenance.

This increase is estimated to be 60 to 75 per cent. The cost for machinery in producing wheat in Minnesota, 1913-1917, was found to be 8.1 per cent. of the total cost.

Cash Threshing Cost, General Expense and Twine. — The minor costs in wheat growing are composed of the cash cost for threshing which is about 5.2 per cent. of the total, general expenses 4.3 per cent. and cost of twine for binding 1.3 per cent.

AGRICULTURAL INDUSTRIES

INDUSTRIES DEPENDING ON PLANT PRODUCTS

358 – **Contribution to the Chemico-biological Study of Micro-organisms Injurious to Winemaking.** — Carino Canina, E. (R. Stazione enologica di Asti), in *Rivista di Ampelografia*, Year I, No. 1, pp. 2-6, bibliography of 10 works, Leghorn, Jan., 1920.

On grapes spoilt by parasites, especially in wet years, besides the ordinary ellipsoid saccharomycetes of wine-producing countries, there are very numerous micro-organisms, which may directly influence the regular progress of alcoholic fermentation. In the natural microflora of the grape, the genus *Botrytis*, *Penicillium*, *Mucor*, *Aspergillus* predominate among the moulds, and *Torula* sp., *Saccharomyces apiculatus*, feeble producers of alcohol, or quite incapable of causing fermentation in grape sugar among imperfect fungi; the action of all these micro-organisms is denoted by the production of unpleasant odours and flavours which be most injurious to

(1) See *Bulletin* 179. *Minn. Agr. Expt. Station.*

the quality of the wine. The genera *Pichia* and *Willia*, characteristic producers of ethers, may also be found.

Generally the micro-organisms of the natural flora of the vintage are active in the combustion of sugars, acids, and nitrogenous substances, and they may secrete enzymes that hinder normal alcoholic fermentation and may produce diseases.

With the help of material obtained from the Zymological Section of the Royal Wine-making Station at Asti, and other strains from the microbiological laboratory of Professor E. KAYSER of Paris, the author has investigated the action of some of these micro-organisms on the groups of principal acids which are normally found in grape must.

Cultures were sown in the must of the "favorita" grape, previously sterilised, kept at a temperature of 24° C. for about fifty days, then analysed. The analytical data obtained for each test are summed up in the following table: —

			Saccharomyces ellipsoideus	*Willia anomala*	*Pichia membranaefaciens*	*Dematium pullulans*	*Penicillium glaucum*	*Botrytis cinerea*
Acidity	free in cc.	N/1 ‰	104.0	103.0	108.0	80.0	59.0	105
	combined in cc.	» »	25.0	27.0	24.0	23.0	22.0	24.0
	volatile in cc.	» »	11.3	22.0	17.0	3.0	3.3	18.5
	fixed in cc.	» »	96.5	81.0	90.2	77.0	56.7	87.0
Acid	tartaric total in cc.	N/1 ‰	50.0	42.0	49.0	49.5	49.5	45.5
	lactic total in cc.	» »	6.75	31.3	14.5	10.5	23.3	21.0
	tannic total in cc,	» »	traces	traces	traces	—	0.0	—
	malic total in cci	» »	61.0	35.0	50.7	46.0	6.0	44
Ethers	totals in gm.	N/1 ‰	0.650	1.850	1.540	—	—	—
	volatile, in gm.	» »	0.300	0.125	0.210	—	—	—
Reducing sugars in gm		» »	3.00	187.0	206.0	193.0	168.0	20.30
Rotary power $[\alpha]^{D}_{20}$			— 0.24	— 6.92	— 8.80	— 7.76	— 7.20	— 7.44
Dextrose, in gm.		» »	1.20	95.5	103.0	97.5	72.4	102
Levulose, in gm.		» »	1.80	91.5	103.0	95.5	96.6	101

These results lead to the following conclusions:—

Pichia membranaefaciens and *Willia anomala* did not sensibly diminish the total acidity, because of the considerable increase of volatile acidity and lactic acid, although a considerable quantity of malic acid was attacked. The total ethers were present in more than normal proportions: dextrose and levulose were consumed in approximately the same degree.

The same may be said of *Botrytis cinerea.*

Dematium pullulans and *Penicillium glaucum* much diminished the total acidity without producing an equivalent quantity of volatile substances; *Penicillium* showed itself the most active acid destroyer; de-aci

dification was produced almost entirely at the expense of malic acid, of which $^{9}/_{10}$ disappeared. The sugars were also been attacked, dextrose with special intensity.

In an experiment tried with must to which 0.179 of sulphurous anhydride per litre had been added, *Saccharomyces ellipsoideus* caused regular fermentation, with a delay of 48 hours ; the other previously mentioned micro-organisms did not develop, and 25 days after they were sown the fermentative activity was practically nil.

359 – **On the " Casse bleue " of Wines.** — CARLES, P., in *Comptes rendus de l'Académie des Sciences*, Vol. CLXIX, No. 26, pp. 1422-1423. Paris, Dec. 29, 1919.

In continuation of the communication made by M. PIÉDALLU to the French Academy of Sciences on Dec. 7, 1919 on the " casse bleue " of wines (1), the author communicates the following note:

This " casse " has already been known for a long time. It was specially studied in 1900 by M. M. LAGATU, L. ROOS, and BOUFFARD at Montpellier. These writers have differentiated it from the " casse brune " of red wines called " casse diastasique ".

M. PIÉDALLU writes that, practically, to prevent " casse " in wines rich in iron, it suffices to keep them in a reducing medium, by simply drawing them off into well sulphured casks, but that it is always preferable to avoid the use of receptacles of unprotected iron for manipulating or preserving the wine. The observations of other writers lead to a different conclusion.

The " casse ferrique " is not controlled by sulphurous anhydride, and if it were possible to keep wines protected from the air by sulphurous anhydride or some other gas, the practical result would not be attained, since all wine, before it is drunk, must be handled, and must inevitably come in contact with the air.

The true treatment of this " casse " consists in adding to the wine an organic acid such as tartaric or citric acid. The latter is more generally used ; with the iron it forms a compound on which tannin, and consequently colouring matters, have little effect. The quantities of tartaric or citric acid vary according to the intensity of the disease and the procedure is to make a preliminary test by commencing, for example, with 50 gm. of tartaric acid per hectolitre and increasing progressively up to 150 gm. or 200 gm. if necessary in certain wines which, like that of Jacquez, are raw materials. Citric acid is used in smaller quantities because it has a stronger action than tartaric acid.

The action of sulphurous anhydride in preventing the " casse ferrique " has no practical effect. This was first shown by BOUFFARD, Professor of Oenology at the National College of Agriculture at Montpellier, who first investigated the " casses " and recommended sulphurous anhydride as a remedy for " casse brune " or " casse diastasique ".

360 – **Quantities of Butter, Cheese and Condensed Milk Made in Factories in the Unite States During the War.** — PIRTLE, T. R. (Statistician for the U. S. Dairy Division), i *Hoards Dairyman*, Vol. LVII, No. 20, p. 1000, 1 diagr. Fort Atkinson, June 6, 191

Making use of (*a*) the census results of 1909, (*b*) those of the manu facturing census of 1914, (*c*) the reports of production of factories issue by the Bureau of Markets for 1916, 1917 and 1918, the author gives, i the subjoined Table, a summary of the quantities of butter, cheese an condensed milk (including evaporated milk) prepared in factories (exclud ing home made products) in the United States during the last ten years

From these results it appears that great progress has been made i the dairy industry during these ten years and that also the condensed mil industry has almost doubled during the war; in 1918, a greater amount c milk was used in the condensed milk factories than was used for cheese

Quantities of butter, cheese and condensed milk made in factories in the United States from 1909 *to* 1918.

Years	Butter (*Pounds*)	Cheese (*Pounds*)	Condensed Milk (*Pounds*)
1909	627 145 865	311 175 730	495 197 84

1916	760 030 573	314 716 739	997 835 11
1917	743 895 068	372 540 203	1 353 605 59
1918	793 289 301	352 621 615	1 675 477 36

361 – **Experimental Study of Electro-Purification of Milk.** — ANDERSON, A. K. a FINKELSTEIN, R., in *The Journal of Dairy Science*, Vol. II, No. 5, pp. 374-406, 2 fi Bibliography of 8 works. Baltimore, Sept., 1919.

The principle of the process of electric purification of milk (electr pure process) consists in heating the milk by means of a high voltage ele tric current, and then cooling it.

The apparatus consists of a receptacle for the milk, of a heater in whic the milk is heated to 40° C. by steam, of a supply tank for the electric p rifier, of a hot milk tank acting as reservoir to the cooler and of a coole

The electro-pure machine itself consists of several units, varying number according to the quantity of milk to be treated. Each unit is cor posed of a series of 5 porcelain cups arranged as in the accompanyi figure. The milk is distributed to the cups by a tap leading from a bo shaped distributing tank. The first cup of each series has about twice t capacity of the other cups. The cups of each series are arranged so that t milk entering the first cup will drain into the second cup, which is plac slightly forward and below the first; when the second cup is filled, the mi overflows by a lip into the third cup, and so on to the last cup of the seri In each of the smaller cups, which have a capacity of about 200 cc. placed an electrode in the form of an insulated rod terminating in copper disc. This disc is about the size of the inside of the cup and when

place is very near the bottom of the cup. When the machine is in operation the circuit is completed by the stream of milk, which by its electrical resistance is raised from 40° C. (the temperature on its entrance into the machine) to 70° C. (the temperature when it passes out). An alternating current is used In the machine illustrated in the accompanying figure the voltage is 2300, the amperage is 14 and the frequency is 25. The three phase system is used.

Electrical milk purifier.

With electric current costing 5 cents per kilowatt-hour. the cost of working is $2.74 per hour for a machine with 6 units, which treats 5000 pounds of milk per hour, exclusive of the cost of the preliminary heating to 40° C.

As the literature on the subject of the efficiency of electrical treatment of milk furnishes but few data, the authors have dealt with the subject by making a series of careful experiments, the results of which lead to the following conclusions: —

The "Electro-pure" process produces a very satisfactory reduction in the total number of bacteria contained in good raw milk and a satisfactory reduction in the bacteria contained in poor raw milk, and at the same

time it destroys effectively nearly all lactose fermenting, endopositive organisms contained in raw milk.

Milk issuing from the different units of the " Electro-pure " machine contains a fairly uniform number of bacteria.

Electro-treated milk kept at 5-10° C. keeps well for about 5 days. At ordinary temperatures it shows no change in 24 hours but sours normally in 48 hours.

The destruction of bacteria in the electric purifier is due to the heat produced rather than to the electric current itself. The electric purifier furnishes a means of producing a very sudden high temperature for a short time.

Heating to 70° C. by means of the electric purifier causes: — Little or no precipitation of albumin ; no modification in the quantity of cream which separates on standing ; apparently no destruction of the peroxidase, but a weakening in the reductase ; no modification in the feeding value of the milk. On the other hand, such treatment increases sensibly the time required for coagulation by rennin. In the experimental plant which was used by the authors, the electric purifier, after long use, was not entirely satisfactory; modifications in construction are required before the machine can be considered a commercial success.

362 – **Study of Babcock Test for Butterfat in Milk.** — BAILEY, D. E., in the *Journal of Dairy Science*, Vol. II, No. 5, pp. 331-373, Bibliography of 28 Works. Baltimore, N. D, September, 1919.

The Babcock test for butterfat in milk is used to a considerable and increasing extent as a basis of payment for milk to be used as such, as well as for condensing and cheese making. It is also used in determining the milk production of individual cows, and hence is an important means of determining their value.

In view of the importance of the test, the author has undertaken experimental work to determine the accuracy of the test as carried out at present, and to study the influence of some factors upon it. The results are summarised as follows :—

1. The Babcock test for milk when read from the top of the upper meniscus to the bottom of the lower meniscus gave results which were higher than those obtained by the gravimetric (Roese-Gottlieb) method. On the average of 190 comparisons, the difference amounted to 0.060 %.

2) There was a considerable variation in the readings of the same sample by a few individuals ; this was largely due to reading at different points on the upper meniscus, and it is believed that the higher readings were made at the top of the upper meniscus.

3. The breed of the cows and the stage of lactation had a small influence on the excess of the Babcock results over the gravimetric determinations. This influence is due in part to the variation in the size of the fat globules and in part to the variation in the percentage of fat present in the sample tested.

4. The amount of fat left in the liquid below the fat column is quite variable and on the average equalled 0.13 % expressed as readings on the neck of the test bottles.

5. There were impurities in the fat column that on the average amounted to 0.78 % of the readings.

6. The Babcock test would read about 0.11 % lower, depending somewhat on the per cent. of fat in the sample, if the meniscuses were not included in the reading. The value of the gain to readings due to the meniscuses more than offsets this low reading, which is in agreement with the first conclusion.

363 – **Utilisation of Dairy By-products.** — KELLY E. (Dairy Division, U S. Department af Agriculture), in *Journal of Dairy Science*, Vol. II, No. 1, pp. 46-49. Baltimore, Jan. 1919

Waste of matter may be caused (1) mechanically (actual loss), or (2) by not using it in the best possible manner (partial loss). The dairy industry unfortunately too often wastes in both ways. Only the surplus skim milk which cannot be used for human consumption, should be fed to animals and ought to be much more employed than it is at present: 100 pounds of skim milk will produce 15 to 19 pounds of "cottage cheese" (1), whereas fed with maize to pigs it would produce only 6 pounds of live weight or 4.8 pounds of dressed pork. There is, therefore, in the former case production of about 7 times as much protein and energy as in the latter. Moreover, in making "cottage cheese" 80 to 85 pounds of whey is recovered from 100 pounds of skim milk, and this has half the food value of skim milk for feeding pigs.

Skim milk and buttermilk can be used in that state as beverages or in cooking. One pound of "cottage cheese" contains as much protein as 1 to 1 ½ lb., of meat, and can be used in a number of ways in cook- This is one of the best ways of using skim milk because "cottage cheese" is easily and simply made and it can be consumed in large quantities. But skim milk can also be used for making condensed skim milk and skim milk powder. Whey from cheese factories contains on the average 0.2 % of fat which can be recovered and used in the manufacture of whey butter. Lactose, casein, etc., can also be made from whey.

All the by-products of the dairy industry, if they are to be used without risk for human consumption (or indeed as animal food), should be pasteurised.

364 – **Observations on the Washing of Milk Cans.** — WEBSTER, R. O. (Bureau of Chemistry, U. S. Department of Agriculture), in *Journal of Dairy Science*, Vol. II, No. 1, pp. 50-59. Baltimore, Jan. 1919.

An account of data collected by the Bureau of Chemistry of the U. S. Department of Agriculture (under the Food and Drugs Act) relating to the milk supply of one of the large cities of the central western part of the United States.

The author notes the methods and equipment used by 32 milk dealers in washing the milk cans: 8 of them washed the cans by pouring the water from one can to another and 22 washed the cans in a tank; only one used hot water and 2 clean cold water, while 28 used dirty water. In 23

(1) See *R.*, Jan., 1920, No. 125. (*Ed.*)

dairies the cans were steamed, but in no case was the treatment effective, so that no dairy washed the cans in a satisfactory manner ; nevertheless 3 dairies possessed what is considered to be the complete equipment : — tank with mechanical brush, rinsing tank, steam jet, air blast.

Examination of the physical and bacteriological condition of 184 empty milk cans returned from the city dairy to the country dairy, made during June and July, showed that 14 cans had a sour odour and 83 a foul odour which indicated bacterial activity in these 97 milk cans. More than 21 % of the cans, if used without further rinsing, would have contaminated the milk with from 500 000 to 4 332 000 bacteria per cc. of milk ; milk produced in distinctly insanitary conditions rarely contains more than 20 000 organisms per cc.

To prevent this fouling of the cans they should be rapidly dried immediately after washing ; this can be done by exposing the milk cans to a blast of dry air ; 30 seconds exposure to such a blast is sufficient to produce a great improvement.

The author gives the following rules for washing milk cans properly : Avoid the use of disinfectants ; they are unnecessary and may remain in the cans in sufficient quantity to be found in the milk, which would render the producer liable to legal penalties.

For the proper washing of the cans a tank with clean hot water is necessary ; washing powder ; thorough brushing by hand or by machine ; rinsing in clean water ; steaming for at least 10 seconds ; drying in a blast of dry, hot air of sufficient volume to dry the can completely in 10 to 30 seconds. The lids should be cleaned in the same way. As soon as they are washed and dried the lids should be put on to close the cans and prevent their being soiled. Milk cans cleaned in this way remain clean indefinitely and even in the hottest weather there is no opportunity for bacterial activity.

365 - **Composition and Identification of Meat Extracts.** — Emery, J. A. and Heuley, R. R., in *Journal of Agricultural Research*, Vol. XVII, No. 1, pp. 1-17. Washington, Apr. 15, 1919.

The Bureau of Animal Industry asked the authors to carry out experiments with the object of obtaining data regarding the differences in composition of extracts of meat prepared from : — Muscle tissue, liver, spleen, heart, cured cooked meat, cured meat soak-water, and bones, all of which have been used in recent years in the preparation of meat extracts.

The extracts used in the authors' investigations were prepared partly in a large commercial establishment in the ordinary way, and partly in the laboratory, in much smaller quantities, but as far as possible by means of methods used commercially ; these latter extracts did not differ from the former either in physical appearance or in organoleptic properties.

The methods used in the analyses were essentially those of Street (described in Thirteenth Report on Food Products for 1908, Meat Extracts and Meat Preparations, in *Connecticut Agricultural Experiment Sta-*

tion Report 1907-1908, pp. 606-672). The authors determined, in a 10 % solution of solid extract or a 20 % solution of liquid extract: — water, ash, sodium chloride, total phosphoric and, inorganic phosphoric acid, total nitrogen, soluble nitrogen, coagulable nitrogen, ammoniacal nitrogen, nitrogen preicipitated by zinc sulphate, nitrogen precipitated by tannic-acid-salt solution, " meat-base " nitrogen (obtained by subtracting from the total nitrogen the sum of coagulable nitrogen + insoluble nitrogen + ammoniacal nitrogen + nitrogen precipitated by the tannic-acid-salt solution), nitrogen due to peptone-like bodies, non-nitrogenous organic matter, purins, creatinin, creatin, and nitrates. A series of Tables show the results in detail as well as some general averages, indicated in the Table below. The quantitative results show the following characteristic differences which depend on the nature of the extract: —

The liver extracts show: — A low percentage both of total nitrogen and of " meat-base " nitrogen ; a low ratio of inorganic phosphorus to total phosphorus ; a very low percentage of total creatinin ; generally a very high percentage of non-nitrogenous organic matter.

The spleen extracts show: — A high percentage of total nitrogen ; a low percentage of " meat base " nitrogen ; a very low percentage of creatinin. The ratio between inorganic phosphorus and total phosphorus is lower than in all other extracts except that of liver.

Extract of	Non-nitrogenous matter	Total nitrogen	Nitrogen in			Creatin + creatinin	Ratio between creatin + creatinin and nitrogen
			Zinc sulphate precipitate	Tannic-acid-salt precipitate	« Meat base		
Muscle, bones, liquors (soaked and cooked)	22.23	9.81	15.90	42.63	50.32	7.25	0.732
Heart	31.65	8.89	8.89	14 17	35.33	7.06	0.796
Spleen (prepared in laboratory)	24.34	9.68	24.76	52.10	38.30	2.40	0.248
Spleen (commercially prepared)		9.94				0.27	0.031
Liver (prepared in laboratory)	41.22	6.21	21.10	55.32	39.26	2.31	0.367
Liver (commercially prepared)		7.33				0 36	0.048

The heart extracts have a low percentage of total nitrogen compared with the muscle extracts, but much higher than that of liver extracts. They contain a considerable amount of non-nitrogenous organic matter and are next to liver extracts in that respect. Heart extracts differ from liver and spleen extracts in their percentages of total creatinin and " meat-base " nitrogen ; in heart extracts the latter forms at least 50 % of the total nitrogen.

The extracts of soaked and cooked liquor of pickled and cured meat are easily identified by the invariable presence of nitrates. The quantity of total phosphorus present in these extracts is very small. In other respects cured meat extracts resemble true meat extracts. Pickled meat extracts contain rather less creatinin than true meat extracts.

Muscle extracts have a high percentage of total nitrogen, " meat-base ", nitrogen and total creatinin ; they also have a high ratio between inorganic phosphorus and total phosphorus.

The bone extracts prepared commercially and the extract prepared from soak-water resemble muscle extracts.

There are also marked differences in the physical properties, colour, texture and " shortness " (an extract is termed " short " when it quickly and easily breaks on testing its elasticity). Liver extracts are very dark brown, their solution in water is dark red with a trace of fluorescence, and they are gummy. Spleen extracts and bone extracts are light chocolate to light yellow-brown in colour. The other extracts are lighter in colour than liver extract but darker than spleen extract; they are usually very " short ". Their solutions are dark but not fluorescent.

In addition to quantitative differences there are qualitative differences, which the authors have used as bases for identification tests for extracts of liver and spleen, either pure or in the absence of any considerable proportion of true meat extracts. These tests include: — The acetic acid test recommended by R. M. CHAPIN for distinguishing spleen extract by means of the abundant yellowish-white precipitate which is formed ; MOLISCH's test, which shows the presence of liver extract ; testiug for copper in the ash, which if present indicates liver extract. The presence of copper is also shown by greenish colour of the ash.

CONCLUSION. — An extract can be completely identified by means of the following determinations: — Total solids, Ash, Sodium chloride, Total phosphoric acid, Inorganic phosphoric acid, Total nitrogen " Meat-base " nitrogen, Pre-formed creatinin, Creatin, MOLISCH' s, test, Acetic acid test, Test for nitrates, Test for copper in the ash.

PLANT DISEASES

DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN.

366 – **Modification in the Sulphate of Iron Treatment for Controlling Chlorosis of Woody Plants.** — ARNAUD, G., in *Revue de Viticulture*, Year XXVI, Vol. LI, No. 1325, pp. 325-330, figs. 2, Paris, Nov. 20, 1919.

Results of experiments carried out in May-June and at the end of September in the Jardin de la Station de Pathologie végétale in Paris, on pear trees and Carolina poplars attacked by chlorosis. These were the only plants attacked by chlorosis available to the author; but he is of opinion that the results obtained by him are applicable to vines similarly attacked.

The suggested method is as follows:— Holes 1.5 cm. to 2 cm. deep are made in the trunk or large branches with a punch; by means of a syringe the holes are filled with a paste made by mixing 35 to 40 gm. of finely powdered sulphate of iron with 20 gm. of olive oil.

The treatment, made preferably in spring, only acts on those parts of the plant which are above the hole.

The treatment in question has the following undoubted advantages over the treatment formerly used, which consisted in placing crystals of sulphate of iron in the holes :— Certainty in effect, at least on the trees experimented with (pear, Carolina poplar), rapidity of action (the trees became green again in a marked degree in a week), and persistency of greenness; moreover, the treatment is very quickly done and economises sulphate of iron, as the syringe fills the holes almost without any waste. However, the method described has disadvantages which are absent from the method of painting freshly cut surfaces with a 20 to 30 % solution of sulphate of iron. The chief drawback appears to be the weakening of the trunk and branches in which the holes are made, especially in the case of young plants not provided with props. Also the addition of oil increases the cost of the treatment; but as inferior olive oil and various vegetable oils would probably be just as effective and the quantity used is small the cost of the treatment should not be much.

367 – **Diseases of the Tomato and the Strawberry New to South Australia.** — Osborn, T. G. B. in *The Journal of the Department of Agriculture of South Australia*, Vol. XXIII, No. 5, pp. 437. Adelaide, Dec., 1919.

In November, 1919, the author was informed of two serious diseases, attacking the tomato and strawberry plant respectively, not previously known in South Australia. There are reasons to believe that the two diseases were in existence before then, but had not attracted much attention. In 1919, they were particularly serious in some districts of the State, causing considerable havoc on certain farms.

In the case of the tomato, the first sign of change is the development of irregular brownish black blotches on the margin of the leaves; similar blotches may appear also on the petioles and on the young stems At the end of some days, the whole plant withers, and frequently dies.

The pathogenic agent not being known, it is not possible at present to combat the disease. It was recorded in Victoria two or three years ago, and from 1918-19, serious loss was incurred.

With regard to the strawberry plant, observations in the Hill district show that apparently healthy plants fade in the space of some hours when the weather is warm; although it is unusual for a plant to die at once during the first season in which it is attacked, it is hindered from regular development, and does not give any crop.

The diseased plants have their young roots darkened. It is believed that the change is due to a soil fungus. Up to the present, this disease has not been investigated.

The disease under discussion can be propagated by planting stolons taken from infected plants. Healthy plants put into fields formerly filled with diseased plants are duly infected. It seems also probable that the disease can be spread from an infected field to an uninfected field by drainage and the carriage from one point to another of infected soil clinging to workmen's boots or to agricultural tools.

The two diseases are being studied by the State Department of Agriculture.

DISEASES DUE TO FUNGI, BACTERIA AND OTHER LOWER PLANTS.

MEANS OF PREVENTION AND CONTROL

369 – **Weather Forecasts at the Station of Agricultural Meteorology at Montpellier in Relation to Control of Mildew and Other Diseases of the Vine.** — Ferrouillat, in *Comptes rendus des séances de l'Académie d'Agriculture de France*, Vol. V, 36 No. Nov. 26 1919, pp. 919-925. Paris, 1919.

After a hard frost, which on March 26, 1898 in theDepartment of Hérault alone, damaged the vines to the extent of about 3 million hectolitres of wine, in a few hours, M. Houdaille, at that time Professor of physics and meteorology at the National College of Agriculture at Mont-

pellier, organised a Service of meteorological and agricultural inquiry, at the request of the Central Society of Agriculture at Hérault. M. RAVAZ, who then was Director of the Research Station for viticulture, undertook to furnish information regarding vineyards. From the following April, the College of Agriculture published, every morning, a Bulletin of information which was posted at Montpellier and at Béziers, the two principal vine-growing centres of the district.

The weather forecast was based on observations of the central meteorological Bureau of France, and especially on those made at the Mont-Aigoual Observatory, which enabled M. HOUDAILLE to forecast, fairly accurately, 48 hours in advance, the temperature, wind and rain at Montpellier.

The notices related particularly to forecasting frosts and the expediency of measures to be taken against fungoid diseases and insects injurious to the vine.

The Service was quickly extended and the Bulletin was brought to the notice of interested parties by means of a daily telegram posted at the town-halls of subscribing communes, and by means of notes inserted in the local press.

The results obtained by the meteorological Station of the College of Montpellier impressed the public authorities and led to the creation, in the Ministry of Agriculture, of the Service of agricultural meteorology.

The College meteorological Station was transformed into the local Station of agricultural meteorology and was installed on the Bel-Air, estate 3 km. from the town of Montpellier and about 1.5 km. from the Agricultural College.

To complete the meteorological information furnished by the local meteorological Station, M. RAVAZ organised 32 small meteorological outposts in the area assigned, recording maximum and minimum temperatures, temperatures during rain, the date, hour and amount of rainfall, the development of diseases, the appearance of insects, etc.

These outposts work as follows:—

(1) Every time rain falls the person in charge at the outpost sends the meteorological Station a postcard stating the amount of the rainfall, the temperature during the rain, the duration and time of the rainfall.

(2) In addition, every Monday, each outpost sends an abstract of its meteorological and biological observations.

(3) All this information is carefully checked on arrival at the Station, and is then methodically classified and entered in a tabular statement; the meteorological observations are also recorded as graphs.

It is thus possible very quickly to get a clear idea of the past and present meteorological and biological conditions of the area served by each outpost.

With the help of all these data, the Director of the Station issuing notices is in a position to predict the course of diseases of the vine and to give suitable instructions. The forecasting of attacks and invasions of

mildew, which, in the south, is the disease most feared, is based on the following principles:— The development of mildew depends on two essential factors, namely, temperature and moisture. It comprises 3 stages :—

(1) The germination and penetration into the plant of active germs, (attack).

(2) The development of the parasite in the invaded tissues, (incubation).

(3) The appearance on the outside of wounds or spots, some sterile (oil-stains), some fertile (efflorescences) (invasion).

For the attack live germs, atmospheric moisture (from rain, dew, and mist remaining for a certain time on the herbaceous organs), and suitable temperature are needed.

The presence of germs is easily detected. When this is ascertained, the attack only depends on the temperature and the persistence of moisture required for the germination of the spores.

Except at the commencement of growth, when a sufficiently high temperature is sometimes lacking, and during the summer, when rainfall is almost immediately evaporated, it may be said that any rain in the growing season starts an attack.

The three stages, which represent the complete evolution of a summer generation of the parasite, have a constant duration, with the vines in full growth in the south of France and under the ordinary conditions of cultivation; this period lasts 7 days. Its constancy is remarkable and this fact makes it possible to predict and announce 7 days in advance the date of appearance of each invasion.

By treating the vines so that they are covered with copper at the time when the attack is about to commence (which is known 7 days before), they are safe for several days from attack by the germs.

There is, therefore, advantage in limiting the treatment to the time when it is really necessary, which produces a considerable saving of fungicide and labour, and obtains the best possible result by applying the fungicide at the precise moment when the effect of the treatment will be greatest.

The practical results obtained in 1918 and 1919 were excellent, and it was possible to fix the most favourable periods for treatment and bring them to the notice of persons interested, by notes in the local press.

There is every reason to expect good results from the method in future.

In addition to mildew, the Station of Bel-Air and its outposts deal with other diseases of the vine and the appearance of its pests (" Cochylis ", " Eudemis ", etc.), by indicating the most suitable dates for their effective control.

370 – **Keeping Bean Seed until it is Old as a Means of Controlling Bacterial Blight of Beans (*Bacterium Phaseoli*).** — RAPP, C. W., in *Science*, New Series, Vol. L, No. 1303, pp. 568 Lancaster, Pa., Dec. 19, 1919.

In the course of research on the bacterial blight of beans (*Bacterium Phaseoli* E. F. Sm.) at the Oklahoma Agricultural Experiment Station

in the United States, it was noticed that the most effective method hitherto evolved for eliminating the disease is the use of old seeds in sowing.

To test this fact, the infected seed obtained from experimental plots at the above-mentioned Station was collected each year and stored. Beans 4 and 5 years old have never produced plants attacked by bacterial blight, but the percentage of germination has been so low as to prevent their use under actual farming conditions. Seed 2 and 3 years old — with one exception ascribed to accidental infection — have given plants free from bacterial blight.

Results obtained, show that the use of seed 2 and 3 years old furnishes plants free from *Bacterium Phaseoli*, when planted in uninfected land and at a sufficient distance from other areas cultivated under beans, to insure the impossibility of accidental infection. Such seed, moreover, has a sufficiently high percentage of germination to make its use practical under actual farming conditions.

371 - ***Colletotrichum Lindemuthianum*, attacking the "Chevrier" Bean, in Austria.** — See No. 316 of this *Review*.

DISEASES OF VARIOUS CROPS

372 - ***Phoma* sp., a Deuteromycete Parasitic on *Cupressus* spp., in South Africa.** — BOTTOMLEY, A. M., in *The South African Journal of Science*, Vol. XV, No 8, pp 613-617; 4 pl. Capetown, 1919.

A severe attack by a disease, then unknown, on some young plants of *Cupressus torulosa* and *C. arizonica* at Belfast, Transvaal; was first noticed in March, 1915. Examination of the diseased plants revealed the presence of three fungi, *Pestalozzia* sp., *Phoma* sp. with typical pycnidia and small globose spores, and another *Phoma* with pycnidia of an unusual shape and rather large fusiform spores. As a result of inoculation and cultural experiments made during the same year it was possible to ascertain that the third fungus was the cause of the disease.

A still more serious outbreak, identical with the first as regards symptoms and results, but showing the presence of the second *Phoma* only, was noticed on *C. macrocarpa* at Pretoria in March, 1918.

Recently the fungus has been identified with a *Phoma* described by HAHN, HARTLEY and PIERCE as parasitic on *Juniperus* spp.

The disease caused by the fungus is characterised by discoloration followed by withering and the death of the leaves and stems attacked; small black dots, which are the fructifications (pycnidia) of the fungus, are present on the dead leaves and stems.

In the inoculation experiments made, wounded plants were infected in a few days, while unwounded plants were, with difficulty, infected only after some weeks. It was discovered that moisture is essential for the development of the disease.

Spraying with Bordeaux Mixture is recommended as an effective means of controlling the disease.

INJURIOUS INSECTS AND OTHER LOWER ANIMALS

RESISTANT PLANTS

373 – **Varying Behaviour of Various Kinds of Tobacco as Regards Insects, in Cambodia.** — See No. 330 of this *Review*.

MEANS OF PREVENTION AND CONTROL

374 – **Comparative action of Chloropicrin on the Injurious Beetles *Calandra oryzae* and *Tribolium navale* (= *T. ferrugineum*)** (1) BERTRAND. — G., BROCQ-ROUSSEU and DASSONVILLE, in *Comptes rendus hebdomadaires des séances de l'Académie des Sciences*, 2nd Half-year, 1919, Vol. CLXIX, No. 26 (Dec. 29, 1919), p. 1428-1430, Paris, 1919.

Tribolium navale F. (= *T. ferrugineum* F.), which lives in the caryopses of damaged cereals, in bran, old flour etc., has been observed by the authors, but only in smaller numbers, in maize, more strongly attacked by *Calandra oryzae* (2). According to a preliminary experiment it appeared to the authors that *T. navale* is unable to attack healthy caryopses, and that it is only able to live on those which are already perforated by *C. oryzae*. It causes less extensive damage than that caused by the other beetle, but nevertheless its destruction is necessary especially in certain determined cases.

It may be supposed that the treatment of caryopses with chloropicrin, in the circumstances previously indicated by the authors, would destroy, at the same time, *C. oryzae* and the other parasites which eventually accompany it. But the authors have shown that, restricting themselves to the limits in strength and time which assure the death of *C. oryzae*, the *Tribolium* beetles resist; and the separation of the two parasites is, so to speak, quantitative.

Does *T. navale* protect itself better than *C. oryzae* in the interior of caryopses? Is it less sensitive to the action of the toxic vapour? In order to prove this the authors measured, in a series of parallel experiments, the comparative action of chloropicrin on *T. navale* and *C. oryzae*, proceding as in their previous experiments.

The results obtained were as shown in the following table, the insects being collected in groups of 10, the capacity of the flask being 8 litres, and the temperature between +14° and +19° C.

These results show clearly that the cause of the separation of the species of insects in the treatment of the infested caryopses is explicable by their unequal resistance to chloropicrin.

The comparative measures have been completed by the following experiments:—

(*a*) In 2 8-litre flasks were placed 6 litres of maize containing *C. oryzae* and *T. navale*; in the first flasks was placed a dose of chloropicrin corresponding to 25 gm. per cubic metre, and into the second a dose

(1) See *R.*, July-Sept., 1919, No. 1049-1050; *R.*, Jan., 1920, No. 148; *R.*; Feb. 1920, No. 274; See also No. 378 of this *Review*. — (2) See *R.*, Jan., 1920, No. 148. (*Ed.*)

Number of grammes of chloropicrin per cubic metr	Fatal time *C. oryzae*	*T. navale*
	h. m.	h. m.
1.	15.0	40.0
2.	8.15	17.30
3.	6.15	10.0
4.	5.10	7.50
5.	4.30	6.15
6.	3.45	5.15
7.	3.35	4.30
8.	3.0	4.15
9.	2.30	4.0
10.	2.15	3.45
15.	1.30	2.50
20.	1.20	2.10
25.	1.5	1.35
30.	0.50	1.20

corresponding to 30 gm. ; after 24 hours all the *C. oryzae* beetles were dead and about 50 % of the *T. navale* beetles remained alive.

(*b*) The conditions were the same as those in the preceding experiment but the time was longer ; after 24 hours only the *C. oryzae* beetles were dead ; after 60 hours all the *T. navale* beetles were also dead.

(*c*) As in *a* and *b* but increasing the quantity of chloropicrin ; with 38 gm. per cubic m. after 48 hours there were still some *T. navale* beetles alive ; with a dose of 40 gm. and after the same time all the insects were dead.

From a practical standpoint it is easy, on a basis of the quantitative results obtained, to determine the necessary conditions for the simultaneous destruction of the two species of beetles. The authors have succeeded, in the case of maize, in treating caryopses enclosed in sacks, exactly as they have described in the case of *C. oryzae* (1), but allowing the chloropicrin to act for at least 24 hours.

INSECTS, ETC. INJURIOUS TO VARIOUS CROPS

375 – ***Tetranychus telarius*, a Mite injurious to the "Chevrier" bean, in Austria.** — See No. 316 of this *Review*.

376 – ***Sphaerolecanium prunastri*, Scale Insect Injurious to Plum Trees, in Italy.** — SILVESTRI, F., in *Bollettino del Laboratorio di Zoologia generale e agraria della R. Scuola Superiore d'Agricoltura in Portici*, Vol. XIII, pp. 70-126, 38 figs. Portici, 1919.

Morphological and biological description of *Sphaerolecanium prunastri* Fonsc., recorded hitherto from France, Bohemia, Italy, North America and Japan. This scale insect is certainly of pale arctic origin. In Italy it has been found in Calabria (Cosenza), Campania (provinces of Caserta and Avellino) Apulia (Altamura), in the Abruzzi (provinces of Campobasso and Aquila), in the Marches (province of Macerata), in Umbria (Bevagna) and in the south of Sardinia.

The favourite host of this scale insect is the wild plum (*Prunus spinosa*), followed by the cultivated plum and, according to certain writers, also the peach.

(1) See *R.* Jan., 1920, No. 148. (*Ed.*)

The damage caused by the insect is direct, by the abstraction o nutritive sap, and indirect by the abundant sugared substance which i ejects by the anus and which serves as food for "fumagines".

S. prunastri has, in Italy, various natural enemies, of which the au thor describes the morphology and biology as well as the respective hyperparasites.

Among the beetles which prey actively on the scale insects are *Exochomus 4-pustulatus* (L.) and *Hyperaspis campestris* Herbst. The larvae of the latter have been found, to a small extent, attacked by *Homalotylus flaminius* (Dalm.).

Among the hymenopterae which have been recorded as parasites o the scale insect are :— *Coccophagus scutellaris* (Dalm.) Westw., *C. howard* Masi. *Phaenodiscus aeneus* (Dalm.) — in their turn attacked by *Cerapterocerus mirabilis* (Westw.), *Pachyneuron coccorum* (L.), *Perissopterus zebra* (Kurdjumov) and by the mite *Pediculoides ventricosus* (Newp.), *Aphicus punctipes* (Dalm.) and *Microterys lunatus* (Dalm.).

377 – **Insects Injurious to the Avocado (*Persea gratissima*), in the Islands o Trinidad and Tobago, West Indies.** — URICH, F. W. in *Bulletin of the Department o Agriculture, Trinidad and Tobago*, Vol. XVIII, Part. 3, pp. 129-131, 2 pl. Port-of Spain, 1919.

Full grown trees of *Persea gratissima* are generally free from insect pests and only occasionally suffer from scale insects and from caterpillars of the moth *Stericta albifasciata* ; on the other hand the Avocado in the early stages of its growth is very liable to insect attacks. During the dry season scale insects find themselves in very favourable conditions for increase, and at the commencement of the rainy season caterpillars may b found in large numbers.

The following insects have been noticed up to date on the Avocado :— (*a*) Ants :— (1) *Solenopsis geminata*, a serious pest to young plants, not only because it encourages and protects the increase of scale insects generally, but also because it eats the tender bark of young shoots and stems ; they can be controlled by destroying the nests with carbon bisulphide and potassium or sodium cyanide; boiling water may also be used; the treatment will be more effective if a little resin wash is added to the boiling water ; if the ants are on the roots and stems, spraying with resin wash and nicotine can be resorted to, but frequent applications may be required as the ants very soon return from neighbouring nests to the plants. Trees can be protected by means of bands painted with special sticky substances; napthalene flakes dusted round a plant will keep ants away for a few days.

(2) *Cremastogaster brevispinosa*, a species of ant less injurious than the preceding one because it confines itself to protecting the scale insects living on the tree without eating the bark; it makes its nest under loose dry bark and in rotten wood ; the nests should be removed as completely as possible and the places should be painted over with crude oil or strong resin wash.

(*b*) Scale insects :— (1) *Pulvinaria pyriformis* ; (2) *Aspidiotus destructor* ; (3) *Saissetia nigra* ; (4) *Pseudococcus nipae* ; (5) *P. citri* ; the first of these is the most common of the five ; hardly an Avocado tree is entirely free from it ; most of the scale insects can be controlled by their natural enemies by keeping ants away from the tree ; when numerous, spraying with nicotine sulphate in combination with resin wash or soap can be recommended.

(*c*) Moths :— *Stericta albifasciata* :— sporadic attacks by the caterpillars of this moth, which destroy the young leaves and flowers of the Avocado are noted ; the caterpillars are gregarious and live in nests made by webbing leaves and branches with silky filaments ; usually the caterpillars are controlled by natural enemies of which the most important is a tachinid fly ; they may also be destroyed by removing the nests and burning them, but this has to be done with care and despatch as the caterpillars, when alarmed, let themselves down to the ground by silken threads and disappear in the grass.

(*d*) Minor pests :— (1) *Selenothrips rubrocinctus* ; (2) *Heliothrips haemorrhoidalis* ; (3) *Aleurodicus neglectus* ; for control, resin wash or nicotine sulphate are recommended.

INJURIOUS VERTEBRATES

378 – **Control Experiments Against Field Mice Made in 1919 in France.** — VAYSSIÈRE, P., RINGELMANN, HALLER and, PLUCHET, E., in *Comptes rendus des séances de l'Académie d'Agriculture de France*, Vol. V, No. 34, pp. 885-889 and 873-877. Paris, 1919.

In 1919 M. P. VAYSSIÈRE first of all made at Léchelle, near Soissons (Aisne), experiments on the use of poisoned baits and in particular with arsenious acid, nux vomica, and carbonate of barium. Rolled oats impregnated with arsenious acid (by means of a barrel turning on a horizontal axis) appears to be specially useful as a bait for distribution in crops damaged by field mice.

But the experiments dealt more especially with, the practical use of chloropicrin (1) in the control of these rodents. This toxic product lends itself easily to treatment on a large scale. It has been applied on over 15 hectares in the Aisne, Oise, and Somme. It suffices (as a measure of precaution) that the workmen should wear protective masks (pattern A. R. S.).

Two methods of treatment have been tried, with pure chloropicrin or an emulsion of 10, 15 and 20 % in potash coconut oil soap. The first inside the mouse holes and the other on the surface of the soil by simply scattering the product. The first of these two methods of destruction would certainly be the most efficacious if it was possible to apply it in practice ; but it is generally impracticable, the number of holes per sq. metre easily amounting to 30 or even 40. With the second method,

(1) See *R.*, July-Sept. 1919, Nos. 1049 and 1050 ; *B.*, Jan., 1920, No. 148 ; *R.*, Feb., 1920, No. 374. (*Ed.*)

about 60 litres of the liquid per hectare are used. Possibly in the future a more rapid method may be devised which would consist, for example, in the use of watercarts furnished with a perforated distributer, at a height of about 10 cm. above the ground. The construction of a special apparatus may also be expected.

The results reported by M. VAYSSIÈRE have suggested the following observations to MM. RINGELMANN, HALLER and E. PLUCHET.

M. RINGELMANN is not in favour of spraying chloropicrin on the soil by any means whatever. The spraying of any liquid leads to the evaporation of this liquid and an heavy discharge of the gas which it contains in solution, which, in the present case, would be dangerous for the workmen. Further, the work of spraying is relatively hard. Finally the speed in advancing should be relatively low so as to apply sufficient liquid per unit of surface.

The application of chloropicrin by watering, if this process is recognised as effective, seems to M. RINGELMANN the most practical; it is only a case of moving a watercart over the fields, which is possible by giving the wheels a width of rim sufficient to prevent them from sinking too deep and thus increasing the power needed for drawing them. The reservoir for the liquid can communicate (by a distributor similar to that described in the case of the introduction of the liquid in the soil) with distributors working over a great width; the apparatus could be moved fairly quickly by using a tractor.

For the introduction of the toxic liquid into the soil a scarifier or cultivator is used whose working parts are fitted behind with a small tube, which allows the toxic liquid to run out to the desired depth, in the required quantity for each metre passed over, the liquid coming from a reservoir fixed on the frame of the cultivator. The reservoir would be provided with a rotary distributer or, what is simpler, mounted like a Mariotte vase, ensuring a constant delivery per unit of time. In any case the materials to be used in construction would have to be resistant chloropicrin, a question which concerns chemists.

M. HALLER observes that any apparatus made of metal, particularly of iron, would be damaged by chloropicrin, as all chlorine compounds attack iron; the apparatus would be useless in a short time. It is necessary, therefore, to use wood or vulcanite, but the apparatus would be too expensive. On the other hand, chloropicrin can only be used until present stocks are exhausted, since if it had to be made specially for controlling field mice the cost would be too high.

Finally, M. E. PLUCHET has suggested a very simple process for the control of field mice, successfully tested by him and which he has seen carried out in La Bauce. This process consists of making, by means of a borer, holes 50 cm. deep in the soil, in the runs of the mice; the walls are smooth, and the field mice who tumble into the holes cannot get out of them. If this method does not destroy all the field mice, at least it destroys a great number.

Agricultural Accounting Offices in Sweden

by Professor H. JUHLIN-DANNFELT
Secretary of the Royal Academy of Agriculture of Sweden.

Since the beginning of 1890, great efforts have been made to speed-up the development of small farms in Sweden, and, in this connection, attempts have been made to encourage the small farmers to keep accounts regularly (1) especially by giving premiums to those that do this. The money required has been furnished by the " Riksdag " which, since 1910, has voted an annual appropriation of 15,000 kronen (2). This sum is distributed to societies for rural economics, or to accounting unions for use in this way, especially to subsidise accounting bureaux to help farmers to keep their books.

With the aid of this State subsidy, seven societies for rural economics and two accounting unions have established agricultural accounting offices. Of these, only the accounting office of the province of Malmöhus has attained any wide activity, whilst, in the majority of the other provinces, the offices have not become important.

In 1916, the General Agricultural Society of Sweden, which had just been founded, established an " exploitation bureau ", with the objects of aiding farmers to keep accounts, to draw conclusions from them that would be of assistance in managing the farm, and to give advice on questions of rural economics.

(1) See *R.*, Feb. 1913, p. 173 for the article by M. L. NANNESON on the Measures Adopted in Sweden to encourage Book-Keeping among Farmers. (*Ed.*)

(2) 1 gold *krona* = 1 *s.* 1 $^1/_2$*d.* (*Ed.*)

By leaving the scientific elaboration of the accounting material from the accounting bureaux to the director of the " exploitation bureau " of the agricultural society, continuity in all that sphere of activity has been obtained.

The provincial accounting offices are made use of mainly by the small farmers ; generally speaking, only 25 % of those making use of the offices have been farmers owning more than 75 hectares, as this is the largest area for which the State subsidy towards accounting expenses can be claimed.

The proportion proprietors and tenants among those using the offices is not known, but it would probably be the same as that found among the farmers in the country, about 16 % of whom are tenants. On the other hand, the " exploitation bureau " of the agricultural society is made use of largely by farmers owning larger areas.

The income of these offices consists chiefly of subsidies from the State and from the agricultural society on which the office depends, together with small sums paid by members of the society or payments for accounts accredited by the office.

The State subsidy reaches a maximum equal to the sum allowed by the agricultural society and may not exceed 15 *kronen* per account. In addition, it can only be paid during the first four years in which the farmer has recourse to the bureau for help. The upkeep of the " exploitation bureau " of the agricultural society is assured solely by the contributions of farmers who come to it for assistance.

Most of the offices have no other expenses save the salaries paid to the persons who administer them, and the salaries usually consist of a small fixed sum plus contributions from the clients. In the only accounting office of any importance, that of the province of Malmöhus, where over 150 accounts were brought in during 1918, the office staff consisted of four persons with salaries amounting to a total of 8816 *kronen*, while the other expenses such as rent, office supplies, etc., came to 1890 *kronen*. The director, who worked 7 hours a day, was paid 4,000 *kronen*, and travelling expenses amounted to 1250 *kronen*.

At the " exploitation bureau " of the agricultural society, the staff consisted of 6 persons ; the director worked seven hours a day, was paid 12,000 *kronen*, and received a travelling allowance of 40 *kronen* a day. As a general rule, the director should have studied agricultural science. A premium is not paid to farmers for neatly-kept account books.

Two main types of accounting are in use :—

Type A : *Simple book-keeping.* — This is intended to give a general view of the economic condition of the farm. The gross return, the cost of working, and the net yield of all the farming economy are calculated ; the income and expenses are distributed among the various branches of the farm, the commercial movement between these branches is ascertained and, if required, the cost of labour is appropriately distributed, so that all the figures and information that can serve as a basis for the economic calculations necessary to guide the farmer can easily be obtained. In

this type of account, no special calculations are made of the special profit and loss appertaining to the different branches of the farm.

Special accounts are opened for: —

1) the farm;
2) the exploitation of the forests (eventually);
3) the household;
4) private consumption;
5) provisions (eventually); and
6) other sources of revenue (eventually).

The accounts will be kept by the system of double entry.

Type B: *Extended book-keeping.* — This consists of the detailed calculation of the profit and loss (special accounts) appertaining to the different branches of farming economy, such as milk production, rearing young stock, pig breeding and, eventually, the different crops. The calculations are sufficiently detailed to show the production costs of the products sold and the transformation value of the products consumed on the farm. This type of book-keeping requires more detailed preliminary data than the former.

The lists and accounts that usually require to be made up are as follows: —

1) Inventory of the assets and liabilities at the beginning and end, respectively, of the financial year;
2) cash account; this also shows the state of credit;
3) account for the products and livestock;
4) day-book showing the hours worked by the men;
5) inventory of dead-stock;
6) account showing the distribution of labour to the appropriate accounts; and
7) household expenses account.

Among these, the first three numbers are always essential, whilst the need for the others depends on the size of the farm, and the extent to which it is desired that the accounts should be kept. In a simpler form of book-keeping, however, the account for products and livestock can be replaced by a household account.

If, in addition to farming, some industry of greater or lesser extent is carried on, such as a saw-mill, flour mill, distillery, starch factory, etc., accounts should be added dealing with these special branches of the farm.

The numbers of audits of accounts made in 1919 consisted of 68 for farms with over 75 hectares of fields and 173 for farms with less than 75 hectares.

During 1918, special studies, based on abstracts of the accounts, were made on 15 properties only. The greatest difficulty met with was the lack of interest shown by the farmers for accounts carefully and suitably kept. The large farmers prefer to keep their accounts themselves, and according to the method with which they are already familiar. The small farmers as a rule keep no accounts at all.

The reports given, do not, therefore, disclose the individual situation of the farmers, and the different farms are indicated by numbers and all the figures are recalculated with hectares as a basis.

ABSTRACTS

AGRICULTURAL INTELLIGENCE

GENERAL INFORMATION

379 – **The Comparative Effectiveness of Certain Culicifuges under Laboratory Conditions.** — BACOT, A. and TALBOT, G., in *Parasitology*, Vol. XI, No. 2, pp. 221-236, 1 fig. Cambridge, February 1919. RURAL HYGIENE

A detailed report of investigations of the comparative efficiency of culicifuges, conducted for the British War Office.

For the purpose of testing culicifuges, numbers of *Stegomyia fasciata* (the yellow fever mosquito) bred in incubators were placed in cages kept in the laboratory. The efficiency of the preparations was tested by coating the forearm with a definite quantity of one or other of them, and exposing in a cage, each test being controlled by inserting after a short interval the other and untreated arm in the same cage, the number of bites being compared in each case. By this procedure it was hoped to obtain a measure of the relative protection which the culicifuges might be expected to afford when used under practical conditions against *Anopheles* mosquitoes.

In the first series of trials, conducted within 15 minutes of application, 8 preparations out of a total of 22 tested gave satisfactory results. Their active ingredients were (1) oil of cassia 1 oz. and brown oil of camphor 2 oz.; (2a) oil of cassia 2 ozs and oil of peppermint, 1 oz; (5) oil of eucalyptus 2 oz. and citronella oil, 2 oz. With liquid carbolic acid 4 drops; (9a) crude naphthalene (coke oven) 3 parts and camphor 1 part, (10) "crude Parasit", (15a) light wood oil, 33 % in a wax preparation; (21) oil of turpentine, 22a) "Lawson's Anti-mosquito Compound". These preparations were then tested to ascertain for what period their protection could be depended upon. Preliminary trials indicated that this period was not likely to extend for more than two hours between treatment of the arm and exposure in the cage. None of the preparations gave complete protection in this series of trials; the most efficient were Nos. 1,21, 2a, 15a, and 9a, over a two hours period.

Observations on the behaviour of the mosquitoes during the tests suggest that the protection afforded does not result from a dislike of the

insects to the culicifuge, but to its obscuring the attractiveness of the human odour.

Regarding the make up of the essential ingredients it was found that fluid preparations were inconvenient and tended to be wasteful in application. Soap preparations, unless very soft, are apt to be difficult of economic use and in either case are more readily dissipated by perspiration than waxy or greasy ones. Culicifuges prepared with grease are more easily applied but are not so lasting as those put up with wax. Soft wax preparations, correctly adjusted to the temperature in which it is proposed to use them, are most suitable for out of doors use. The retarding of volatilisation caused by the admixture of the active ingredients with wax or grease is a distinct advantage, but care must be exercised in respect of the relative proportion of active substance to the base. The golden rule is to use as much of the active constituent and as small a quantity of the inert base as is consistent with convenient application and the prolongiation of the period of efficiency.

380 – **The Superiority of Carbohydrates to Fats, in their Action of Economising Albumin, is Compatible with the Superiority of Fats over Carbohydrates in the Utilisation of Albuminoids** (1). — MAIGNON, F., in the *Comptes rendus des Séances de la Société de Biologie*, Vol. LXXXII. No. 34, pp. 1358-1360. Paris, December, 27 1919

The facts known may be summarised as follows :—

1) The administration of carbohydrates to a starved dog reduces the nitrogen excreted in the urine by 55 % (WIMMER), while with fat, the reduction amounts to 2 % only (A. BARTMANN).

2) In man, a fat diet increases the nitrogenous excretion compared with a mixed diet, whilst a carbohydrate diet reduces it (CATHCART).

3) In feeding meat with carbohydrates, the fixation of albumin in the dog is slightly greater than when feeding fats and meat ; it is about 5 % greater (C. VOIT, ATWATER). The same result is obtained by replacing the albumin with a mixture of amino-acids (LÜTHJE).

The action on the fixation of albumin can be explained either by a better utilisation of the proteins with carbohydrates, or by admitting, with LANDERGREEN, FALTA and GIGON, that the organism always has need of sugar and that fat, which cannot supply it, as the author helped to show in the case of mammals, makes it necessary to destroy a supplementary quantity of albumin in order to provide for the formation of glycogen.

The first hypothesis does not explain the economising action ; in addition, it is contrary to experimental evidence which shows that fats are superior in the action they exercise on the way in which the albuminoids are utilised. These facts may be stated as follows :—

(1) See also *R.*, Nov. 1918, Nos. 1195 and 1196. (*Ed.*)

1) In the white rat, egg-albumin, whose ingestion is never followed, as with fibrin and casein, by an excess of fat in the liver, is the only one of these three proteins which is affected by the season and has periods of great toxicity during the spring and autumn.

2) The addition of a small quantity of fat ($^1/_5$) to this same albumin does away with its great poisonous effect.

3) With mixtures of egg-albumin and fat, a constant weight can be maintained for a prolonged time, much more easily and often than with mixtures of egg-albumin and starch.

4) The minimum quantity of albumin that has to be introduced into the ration to obtain this result is much greater with starch than with fat (1 : 3).

On the other hand, the optimum ration of egg-albumin and fat that will keep the weight constant, contains fewer calories than the corresponding ration of egg-albumin and starch.

Therefore, albumin is better utilised with fat than with starch ; it is less poisonous and its food value is higher.

5) Casein, which is made use of by the dog without the help of the reserve fats (constant weight), is much more toxic to that animal (fatty disintegration of the kidneys, arteriosclerosis of the myocardium), than to the white rat, whose weight cannot be kept constant.

The second theory, based on the need for the presence of carbohydrates in the organism, explains both the saving obtained and the action on the fixation of albumin. In the case of albumin-fat rations, two factors tend to make the quantity of albumin required vary inversely ; on the one hand, the necessity for forming glycogen at the expense of part of the albumin ingested, and on the other, the better utilisation of the part left over for protein-formation. There is nothing surprising in the fact that, in the dog, which has a greater power of protein-utilisation than the white rat, as the author's experiments have shown, the former influence predominates, while the latter preponderates with the rat. The author has already pointed out that, in problems of nutrition, the species of animal made use of must be taken into consideration. Thus, the results obtained with the white rat are in no way opposed to those obtained by C. Voit, Atwater and Lüthje with the dog. The theory of the superiority of fats with regard to the utilisation of albuminoids also obtains a striking confirmation from clinical and rearing practice and chemical experiments (L. C. Maillard).

Crüsius and the zootechnicians are, generally speaking, agreed that the most suitable rations for fattening animals are those that are rich both in protein and fat. The clinical effects obtained by administering vegetable oils in the case of cachetic diseases accompanied by nitrogenous denutrition — diabetes, tuberculosis — showed an extremely marked economy as regards the destruction of albumin, which can only be explained by the intervention of fats in the nitrogenous metabolism. The chemical researches of L. C. Maillard also show the superiority of fats over carbohydrates in protein formation.

381 - **The Vitamine Problem** (1). — PUGLIESE A., in the *Reale Istituto Lombardo di Scienze e Lettere, Rendiconti*, Series II, Vol. LII, Pt. 16-18, pp. 723-730 + Bibliography of 8 Works. Milan, 1919.

Of late years, vitamines, the composition and reaction mechanism of which still remain to be cleared up, have been added to the nutritive principles considered to be necessary in alimentation.

According to the modern conception of the vitamines, they are not only matter necessary for the proper functioning of the organism and for repairing the wastage introduced with the food, but are also substances with the function of regulating the exchange, so that the organism has a triple regulating system ; 1) nervous ; 2) humoural ; and 3) another outside the organism and depending on substances that occur in minimum quantities in the food.

Vitamines have been compared to hormones, as they both act in minimum quantities, offer considerable resistance to heat, and act in the chemistry of the body. But, according to the author, vitamines should be clearly distinguished from hormones properly so-called, products of very differentiated secretions of the endocrinal glands, which originate from the metabolism of the body and constitute its " humoural correlation ". Hormones, on the contrary to vitamines, act in the same way on very different animals, and are not destroyed by sterilisation.

It is still more erroneous to consider vitamines as enzymes. The author has found that pigeons, even very young ones, fed for several months solely on hulled, but not polished, rice, heated for a few hours to 100-105°C. (a temperature which certainly destroys the enzymes contained in the seeds of cereals), grow very well ; rice heated in this way, perhaps owing to the aroma caused by roasting, is even much liked by pigeons. " If it is not admitted that vitamines are comparable to hormones and enzymes, their mode of action becomes too obscure, and their actual existence becomes doubtful ",

The harm caused by rearing with sterilised milk can be explained much better than with the vitamine theory, by the incomplete observation of the meticulous care required by sterilisation, and better still by the relative heterogeneity of cows' milk in relation to maternal milk.

The author also thinks that it is not possible to attribute to vitamines, such as most people now understand them, the results obtained, mainly by American workers, by studying growth development, due to the addition of milk, butter, or extracts of plant or animal foods to a known food mixture.

As regards adult animals, few diseases can be classed among those due to lack of vitamines, e. g., beri-beri, scurvy, pellagra, and possibly only the first of these.

(1) See also *R.*, April 1916, No, 415 ; March, 1917, No. 260 ; June, 1917, No. 556 ; January, 1918, No 2 ; February 1918, No. 125 ; August, 1918, No. 834 ; January, 1919, No. 6 ; October-December, 1919, Nos 1068-1072 ; January, 1920, Nos 3, 4, 5 ; February, 1920, No 157. (*Ed*).

When guinea-pigs, which are eminently phytophagous, are fed solely on seeds, their urine, which, as with most herbivora, is alkaline and almost or entirely free from phosphorus, becomes very acid and rich in phosphorus ; it contains more lime and ammonia and occasionally, so the author has found, even acetone and fatty acids. There is a rapid and acute loss of minerals from the body, especially phosphorus and lime.

The various experimental animals, even those belonging to the same species, show a very different resistance to a given dry food ration as regards the period at which the repugnance for food first appears ; those animals that lose appetite at the latest date are those that show the perversion of their food exchange most slowly.

With guinea-pigs fed on dry hay, the quantity of urine decreases, but remains very alkaline and with very little phosphorus ; this, therefore, excludes the possibility that the injurious action of dry seeds on guinea-pigs and rabbits might be due to their lack of water. The essential difference between dry seeds and dry hay lies in the fact that the latter has a much higher content of salts and contains aromatic substances which make it appetising for all herbivorous animals.

Dr. G. Rossi (" Sullo scorbuto sperimentale. La possibilità di una sterilizzazione ad elevate temperature, la quale non alteri il valore alimentare delle sostanze sterilizzate, *Archivio di Fisiologia*, Vol. XVI, pp. 125. 1918) found that grass sterilised in a closed vessel and which consequently retains its aroma, is excellent, on the contrary to grass sterilised in a closed vessel, for feeding guinea-pigs.

For this reason, the author considers it as not proved that the trophic disturbances encountered in feeding with dry seeds depend on the lack of antiscorbutic vitamines, but rather that they are due to changes in the reaction of the organic liquids, resulting in an intensely acute loss of mineral matter from the organism, especially phosphorus and lime. He believes that the problem belongs mainly to the domain of physical chemistry, and he is continuing to work in this direction.

382 – **Researches on the Fat-soluble Accessory Substance.** — Drummond, J. C., in *Biochemical Journal*, Vol. XIII, No. 1, pp. 81-94 ; 95-102. Liverpool, February, 1919.

I. — *Observations upon its Nature and Properties.* — The standardised method adopted by the author in testing substances for the presence of fat-soluble *A* is as follows : young healthy rats weighing about 50 gm,. each were fed upon an artificial ration consisting of purified casein 20 parts + purified starch 50 parts + salt mixture 5 + yeast extract (source of water-soluble *B*) 5 + butter fat (source of fat-soluble *A*) 15 + filtered orange juice (source of the antiscorbutic factor or water-soluble *C*) 5 parts. The rats which give evidence of a normal power of growth were removed from the complete ration when they attained an average body weight of 70 to 80 gm. and were given a similar dietary in which the butter fat was replaced by an equivalent amount of hardened linseed oil which is known to be deficient in fat-soluble *A*. When it was definitely established that growth was inhibited by this deficiency of fat-soluble *A*, the linseed oil was wholly

or partially replaced by the substance to be tested and the behaviour of the animal closely watched for a period of from 4 to 6 weeks. Absence of fat-soluble *A* was indicated by failure to grow, followed by a decline in health accompanied by the characteristic eye condition.

The results obtained in a study of the properties of fat-soluble *A* according to the above method are summarized as follows :—

Fat-soluble *A*, present in certain oils such as butter fat and whale oil, is readily destroyed by exposure for one hour to a temperature of 100° C. ; by exposure for a longer period of time to temperatures ranging from 50° to 100° C., and by exposure for several weeks to a temperature of 37°. The destruction is apparently not a result of oxidation or hydrolysis.

Fat-soluble *A* is not extracted from oils by water or dilute acid, but is soluble in alcohol and may be removed in small quantity from oils by cold extraction with alcohol. Hydrolysis of oils in a non-aqueous medium at room temperature causes disappearance of fat-soluble *A*.

In regard to its composition, fat-soluble *A* has not been identified with any of the recognized components of fats such as glycerol, saturated or unsaturated fatty acids, cholesterol, lecithin, phosphatids, or lipochromes. No evidence has been obtained to suggest that it is not a single substance, but indications point to its being a labile substance of ill-defined constitution.

II. *Observations on its Role in Nutrition and Influence on Fat Metabolism.* — The studies reported in this paper concern the indispensability of fat-soluble *A* in the diet of the adult and the connection between the metabolism of fat-soluble *A* and the fat of the diet.

Feeding experiment conducted according to the method described above indicate that the adult animal organism requires a regular supply of fat-soluble *A* which is much smaller than the requirement of the young growing animal, but is an important factor in the maintenance of health. It appears probable that the resistance to diseases of bacterial origin is seriously impaired by a failure of the animal to obtain a sufficient supply of the fat-soluble factor. There is therefore every reason that great care should be taken to insure that dietaries of adults contain an adequate supply of foodstuffs in which fat-soluble *A* is present.

The symptoms associated with a deficiency of fat-soluble *A* appear in comparable groups of rats after the same period of time whether the diet contains neutral fat or not. This, together with the fact that fatty acids are absorbed and synthesised into fats, and fats are absorbed in the absence of fat-soluble *A*, is thought to suggest indirectly, that pure neutral fats may be dispensable components of the diet.

GRICULTURAL METEOROLOGY

383 - **Comparative Studies on Evaporation carried out under Identical Experimental Conditions, in the U. S. A.** — Shrell, C. A., in *The Plant World*, Vol. XXII, No. 7, pp. 210-215. Tucson, Arizona, July, 1919.

Some years ago, the United States Department of Agriculture commenced a series of large-scale researches in order to study the progress of evaporation under standardised conditions that were typical and uniform.

A few stations were already in existence in 1916, but more were added so as to form a close network stretching over the whole area of the country particularly in the driest regions in the west. By January, 1918, there were 30 stations on the continent and one at St. Juan (Porto Rico).

TABLE I. — *Monthly evaporation, air flow, and monthly temperature data.*

Date	Evaporation in inches	Air flow average miles per hour	Temperature Fahrenheit
August. 1916	8.245	4.25	79.19
September . . . . . »	7.761	4.62	67.17

November . . . . . »	2.013	6.92	52.4
March 1917	5.953	7.87	44.9
April . . . . . »	5.681	6.61	52.8
May. . . . . »	5.701	3.73	58.2
June. . . . . »	8.385	3.525	71.65
July. . . . . »	11.061	2.83	80.4
August. . . . . »	6.956	2.09	73.57
September . . . . . »	5.445	2.61	69.35
October . . . . . »	4.114	3.645	50.64
November . . . . . »	3.079	3.72	47.4
April 1918	4.821	4.03	48.45
May. . . . . »	8.453	5.2	68.35
June. . . . . »	9.325	2.65	77.45
July. . . . . »	9.881	2.76	77.6
August. . . . . »	12.020	3.42	83.71

These stations, both by their orientation and by the arrangement and construction of the instruments, are arranged in such a way as to obtain the greatest possible uniformity in the experimental conditions. The pan has a diameter of 48 inches and a depth of 10 inches. The collection of data (under uniform conditions of observation) from regions with great differences of climate, will make it possible to make a comparative study of the climates in the different sectors of the United States, by providing the elements of the scientific ecological examination of the agricultural environment.

The distribution of the movements of the air during the year should be correlated to a certain extent with the growth of the vegetation. This has little effect in spring and autumn, but as spring merges into summer and the foliage increases, the covering of vegetation offers an increasing resistance to the displacement of the surrounding mass of air. At the same time, the convection currents are more energetic at the beginning and end of the season, on account of the rapid and frequent variations of temperature. The correlation coefficient between evaporation and air movement is apparently lower ($r = +0.29 \pm 0.027$) than the correlation coefficient between evaporation and temperature. This second correlation is well illustrated by Table II.

TABLE II. — *Correlations between evaporation and temperature.*

Average daily temperature (Fahrenheit)

Daily evaporation in inches.	10°	20°	30°	40°	50°	60°	70°	80°	90°	100°	*Totals.*
0.100	1	2	19	35	9	8	6	—	—		80
0.200	—	1	8	29	42	40	28	1	—		149
0.300	—	—	—	6	28	36	54	16	—		140
0.400	—	—	—	1	7	17	39	34	—		98
0.500	—	—	—	—	—	2	11	21	2		36
0.600	—	—	—	—	—	1	3	11	—		15
0.700	—	—	—	—	—	—	—	1	1		2
0.800	—	—	—	—	—	—	—	—	3		3
0.900	—	—	—	—	—	—	—	1	—		1
Totals.	1	3	27	71	86	104	141	85	6		524

The coefficient of correlation between temperature and evaporation is 0.687 ± 0.0156. The evaporation is, of course, calculated from the free surface of the pan; the conditions are much more different in the case when the evaporation takes place from the surface of the soil or of plants, a subject about which little is as yet known.

In any case, the large mass of data collected under uniform experimental conditions will greatly aid in facilitating the analysis and comparative study of climatic conditions in relation to ecology in general.

384 – **Cultural Tests of Wheat in Tonkin with Regard to Local Climatic Conditions** — See No. 416 of this *Review*.

385 – **The Effect of Meteorological Factors on the Growth, Morphology and Yield of the Tepary Bean (*Phaseolus acutifolius* var. *latifolus*).**. — HENDRY G. W., in the *Journal of the American Sociiety of Agronomy*, Vol. II, No. 6, pp 247-252 + 1 Plate. Washington, September, 1919.

The unusual capacity possessed by *Phaseolus acutifolius* A. Gray var. *latifolius* Freeman, of adaption to a very arid climate and environment,

was described by FREEMAN in 1912 at the Arizona Agricultural Station. Since then, this leguminous plant has become one of the most important crops cultivated in the arid districts in the south-west and it is already spreading to the valleys in the interior of California. By 1918, the area covered by the tepary bean in this region amounted to over 22 million acres.

From a series of experiments and cultural tests carried out during the last five years in various Agricultural Stations in California, it has been found that the type of climate in which *P. acutifolius* prospers is well defined in certain of its most characteristic elements.

An accurate study was made of the effect of meteorological conditions on the growth of the bean, and its behaviour in relation to the cool coastal climate prevalent in the maritime regions of central and northern California.

Plants growing in the semi-arid districts in the interior of the country have a spreading and clinging habit, and, under favourable conditions may attain a total length of 40 feet. On the contrary, however, plants growing in the damp coastal regions to the north of Point Conception, develop abnormally :— 1) they become bushy, compact, with a tendency to a dwarfed condition ; the tendrils are lacking and the plant is rarely longer than 18 inches ; 2) the leaflets are smaller and thicker ; 3) the pods are more numerous, short and broad, with few seeds ; 4) the seeds take on a characteristic grey colour ; they absorb moisture directly from the air and become larger to a certain extent ; they often begin to germinate within the pod before the plant stem is full grown ; 5) the period of growth is prolonged indefinitely and the foliage remains green until destroyed by the first autumn frosts.

PRODUCTIVITY OF *P. acutifolius* IN THE ARID REGIONS IN THE INTERIOR OF CALIFORNIA. — Cropping tests were carried out in three localities, Davis, Fresno and Riverside, situated in northern, central and southern California respectively.

The figures showing the yields of *Phaseolus acutifolius* and *P. vulgaris* are given in the following table :—

Localities	Number of years	Avarage yield in lb. per acre	
		Phaseolus acutifolius	*Phaseolus vulgaris*
Davis	3	813	469
Fresno	2	2998	321
Riverside	1	3111	681

Owing to its greater resistance to drought, *P. acutifolius* does better than *P. vulgaris*, and shows up more and more as a crop particularly suited to all the semi-arid belt.

PRODUCTIVITY OF *P. acutifolius* IN THE DAMP, COASTAL REGION OF CALIFORNIA. — Comparative cultural tests were carried out at the Berkeley (central coastal region), Santa Cruz (south-central coastal region), and Smith River (northern coastal region) Stations. The yields were as follows :—

Localities	Yield in lb. per acre	
	Phaseolus acutifolius	*Phaseolus vulgaris*
Berkeley	1244	1512
Santa Cruz	—	562
Smith River	155	683

In these localities, *P. acutifolius* was clearly inferior to *P. vulgaris*. The requirements and climatic limits of the tepary bean are thus fairly clearly determined, as it is plainly xerophilous and incapable of adapting itself to a damp climate.

RELATION OF THE CLIMATE AND DATE OF PLANTING TO THE PRE-FLOWERING PERIOD. — The duration of this period is so much the longer, the lower the temperature is, and the differences observed with varying dates of sowing can be explained by the diversity of the temperature conditions to which the plants are exposed in the early stages of their development. The most important figures relating to this are given below :—

Berkeley (damp, cool)		Davis (warm, arid)	
Date of sowing	Duration of period between sowing and flowering.	Date of sowing	Duration of period between sowing and flowering
May 1	80 days	April 13	91 days
May 17	78 »	May 30	51 »
July 2	77 »	July 5	42 »
Average	**78** days	*Average*	**61** days

The abnormal duration of 91 days in the case of Davis, with sowing on April 13, is due to a series of abnormal depressions of temperature which occurred after sowing.

The following table, which gives the average monthly temperature for the period from April to December, gives a still better illustration of correlation between the temperature and the period between sowing and the beginning of flowering.

Month	Average temperature		Meses	Average temperatura	
	Berkeley	Davis		Berkeley	Davis
April	13.11° C	14.22° C	September . . .	18.94° C	22.00° C
May	12.94°	15.61°	October	17.22°	19.33°
June	16.67°	22.83°	November . . .	14.22°	12.06°
July	17.22°	25.94°	December . . .	12.67°	8.89°
August	15.61°	23.89°			

Relation of the climate and the date of planting to the flowering period. — This case is very similar to that of the duration of the period between sowing and flowering. The details are given below :—

Berkeley		Davis	
Date of sowing	Duration of flowering	Date of sowing	Duration of flowering
May 1	57 days	April 13	44 days
May 17	35 »	May 20	35 »
July 2	74 »	July 5	35 »
Average	**55** days	*Average*	**38** days

Relation of climate and date of planting to the life period (from sowing until the plants are completely mature). — This case is similar to the previous one.

Berkeley		Davis	
Date of sowing	Duration of vegetative period	Date of sowing	Duration of vegetative period
May 1	157 days	April 13	148 days
May 17	135 »	May 30	96 »
July 2	166* » +	July 5	92 »
Average	**153** days +	*Average*	**112** days

* Killed by frost prior to maturity.

The plants sown on July 2 at Berkeley were destroyed by the frosts in December before they were mature.

Conclusions. — 1) *Phaseolus acutifolius* has been cultivated in the cool regions of central and northern California (coastal sectors), where it grew normally.

2) It is more productive than *Phaseolus vulgaris* in the semi-arid districts in the interior of California.

3) It is, however, less prolific than *P. vulgaris* in the damp and cool regions along the coast-line.

4) The duration of the life period, of the period between sowing and the beginning of flowering, and of the flowering period is in a direct ratio with the climatic conditions; it is longer as the temperature is lower.

386 – **The Effect of Low Temperatures on The Floral Buds of the Peach Tree as Regards their Water Content.** — See No. 398 of this *Review*.

387 – **The Capillary Rise of Water in Soils.** — KENN, B. F., in the *Journal of Agricultural Science*, Vol. IX, Pt. 4, pp. 397-399. London, 1919.

The height to which water can be lifted in the soil by capillarity is the subject of varying opinions, the height being variously estimated at from 60 to 90 cm., up to 2 to 3 kilometres, although it is rarely more than 60 metres. MITSCHERLICH, working from the heat of wetting, arrived at the enormous figures of 2 to 3 kilometres, although he obtained esperimentally a rise of only 80 cm. in 3 months.

The author suggests a direct calculation of what may be considered as the probable maximum capilliary lift. Starting from the formula $h = \frac{4\sqrt{3T}}{\delta g K}$, where T is the surface tension, δ the density of water, g the force of gravity, h the height to which water would reach in a tube whose cross section is an equilateral triangle of side K, which constitutes a model of the forces in an "ideal" soil with uniform spherical particles, by successive approximate simplifications, we obtain the formula $h = \frac{0{,}75}{r}$, where r is the radius of the soil particles.

If this formula is applied to the dimensions of the soil particles obtained by the ordinary mechanical analysis, we obtain the following values :—

Soil fractions	Diameter	Capillary rise
Fine gravel	1–3 mm	5–15 cm
Coarse sand	0.2–1	15–75
Fine sand	0.04–0.2	75–375
Silt	0.002–0.04	375–7500
Clay	0.002	7500

These figures show that the possible capillary rise of water in the soil increases rapidly with decreased dimensions of the soil particles. In practice, these figures would obviously require considerable reduction, because soils are naturally composed of a mixture of particles of all shapes and sizes, in which the capillary spaces are irregular in length, width and direction, so that the possibiiity of capillary rise is considerably reduced.

Again, the trapping of air in the interstices add to it as well as the colloidal portion (in heavy soils) which, by expanding, closes up the pores. Thus the figures in the appended table represent the maximum limits for actual soils with the same porosity, and they are probably much higher than those actually found in practice. In addition, laboratory experiments show minimum values for the capillary rise of water, because it is not possible to reproduce the various meteorological and hydrological factors which, in the open soil, tend to assist capillarity by making the soil and sub-soil more compact.

388 – **Quantitative Relations between Soil and Soil Solution shown by Freezing-Point Determinations.** — KEEN R. F., in *The Journal of Agricultural Science*, Vol. IX, pp. 400-415, + 4 Figs. London, 1919.

After recapitulating his own work on soil evaporation (1), which showed the existence of close relations between the soil and its moisture the author discusses the work of BOUYOUCOS and his collaborators first by the purely qualitative dilatometric method, then by determinations of the freezing-point, a drop in which, enables quantitative relations to be established, especially as regards the " unfree " moisture in the soil, in contrast with the " free " moisture.

By analysing the experimental data obtained by BOUYOUCOS and his collaborators on the lowering of the freezing point of the soil solution with a varying moisture content and determined *in situ*, the author shows that, in quartz sands and in soils of an extremely sandy type, the soil solution obeys approximately the same laws as dilute solutions, as the lowering of the freezing point varies with the concentration or inversely as the moisture content. In other words, if Dn is the freezing-point depression Mn the moisture content, and K a constant, then $Mn\,Dn = K$. But ordinary soils do not obey this law, as the freezing point increases rapidly with increasing moisture, which BOUYOUCOS explains by the fact that part of the water is neither free nor fixed, so that it has no influence on the lowering of the freezing point. The author, accepting these hypotheses, discusses the quantitative consequences and deduces that :— 1) The water which is not freed does not represent a constant amount, but varies with the moisture content ; 2) there are, therefore, definite relations between free, fixed, and total moisture, and if Mn be the total moisture, Yn the free moisture, Zn the fixed moisture, c and x two constants of any soil, these relations can be expressed by the two equations $Yn = cMn$ and $Zn = \frac{1}{c^{\frac{1}{x}}}\, Yn^{\frac{1}{x}} - Yn$; 3) the ratio of moisture or of free water to total water continually decreases and the ratio of the water that is not free increases with the decrease of total water, and that within experimental limits.

(1) See *R.* 1915, No. 248.
(2) See *R.* 1919, Nos. 151 and 567. (*Ed.*)

Although the actual content of free water decreases with the decrease in the total water, it is impossible to find in what degree the actual content of fixed water varies with the decrease in the total moisture. This uncertainty is explained by the presence of an unknown, but invariable factor in the constant c of the equation given above, and which depends on the limits of the experiments of BOUYOUCOS. In any case, the author's general conclusions are of value in relation to his researches on the evaporation of soil water, *i. e.*, that the soil colloids should be considered first in this phenomenon, that the soil water is always submitted to the same law under experimental conditions, and that the various constants and critical points only represent approximate equilibrium values, without indicating sudden changes in the physical conditions of the soil water.

389 – **The Sterilisation of Soil by Steam.** — POLAK, M. W. (Institut voor Phytopathologie van de Landbouwhoogeschool Wageningen), in the *Mededeelingen van de Landbouwhoogeschool*, Vol. XVII, Nos. 1, 2 and 3, pp. 91-108 + 2 Figs. + 1 Plate. Wageningen, 1919.

The author has continued the work of RUSSELL and PETHYBRIDGE (1) and several American authors on the sterilisation of soil by steam. The experiment was carried out in a greenhouse at the Phytopathological Institute at Wageningen by passing steam through tubes, with a breadth of 70 cm. and a length of 8.5 metres, laid along the axis of a trench dug out of the soil.

The consumption of steam per square metre of soil to be heated was calculated from the formula $Q = 10\ dsct$, where Q is the number of large calories required, d the depth in centimetres of the soil to be sterilised, t the temperature to which the heating is carried out, s the specific gravity of the soil, and c its specific heat. In order to find the number of kg. of steam required, we get $S_t = \frac{Q}{550} = 10\ \frac{d\,s\,c\,t}{500}$; and, with a temperature between 95-100°C., say $t = 96°$ C., we get $S_t = 1.75\ dsc$; the amount of steam required S_p equals $1.75\ dsc = V$, where V represents the loss of steam in kg., which, in the experiment, amounted to 17.5 kg., so that $S_p = 1.75\ dsc + 17.5$. If K be the quantity of coal required to produce this steam, and assuming that 1 kg. of coal produces 7 kg. of steam, then $K = \frac{d\,s\,c}{4} + 2.5$.

In the experiments, d = about 40 cm., $s = 1.2$, and $c = 0.35$, so that $K = 6.7$ kg., and the steam required to sterilise one square metre of soil would be about 47 kg.

The practical question is to find whether it is better to sterilise the soil or bring fresh soil in, to avoid the appearance of soil fatigue, and it depends, apart from the theoretical question, on the installation already available and the relative costs of the two operations.

390 – **The Effect of Temperature on the Loss from Canals due to Infiltration.** — CRANDALL, I., in the *Engineering News Record*, Vol. LXXXII, No. 7, pp. 323-324 + 2 Diagrams. New York, February 13, 1919.

IRRIGATION AND DRAINAGE

The author examined the losses through infiltration from canals forming part of an irrigation scheme in southern Idaho, and extended his researches to an irrigated area of about 2559 acres. He found that the loss due to infiltration increases with the temperature of the water. Usually, the variation in temperature during a period of irrigation, (from about 10-21° C.) may lead to a variation of 30 % in the loss due to infiltration, as shown by the appended table :—

Ratio between the loss of water at various temperatures and the loss at 45° F. (taken as equal to 100).

	Losses at		
	50° F	60° F	70° F
Losses calculated by the formula of HAZEN	109	128	146
Losses calculated by the formula of SCHICHTER	107	125	143
Losses found in the North Side Canal System, except Jerome reservoir; averages of 1916-1917	108	125	141
Losses found in Jerome reservoir (maximum depth, 16 ft. 6 in.)	123	173	218
Losses from Lake Wilson:			
Depth 10 ft.	114	132	165
» 14 ft. 6 in.	118	148	182
» 19 ft. 6 in.	122	158	192
» 24 ft.	126	166	200

391 – **Experiments on the Improvement of Peaty Soils by means of Sand, in Denmark.** — HANSEN, J., in the *Tidskrift for Planteavl*, Vol. XXVI, Pt. 4, pp. 553-622. Copenhagen, 1919.

PERMANENT IMPROVEMENT DRAINAGE AND IRRIGATION

Experiments carried out from 1899 to 1916 at the Agricultural Station at Askov, in conformity with the resolution passed at the Agricultural Congress of Copenhagen in 1888, in order to study the effect of covering a typical super-aquatic peat soil some 10 to 16 feet deep with a layer of mineral soil. The improvement was begun in 1899 and, in 1902, three series of plots were marked out in 8 fields each 700 sq. metres in area. One plot was given a dressing of sand 5.2 cm. thick, the second a dressing of sand 10.4 cm. thick, and the third acted as a control. Later on, the sand was incorporated into the peat by ploughing. The crop rotation, after 1906, was :— 1) rye ; 2) leguminosae (peas and beans) ; 3) hold crops (potatoes, mangolds and turnips) ; 4) oats with clover and fodder grasses ; 5-8) clover and fodder grasses. The appended table shows the yields obtained, in quintals per hectare :—

The effects of improving the soil with sand varied during the experimental period. At first, the yield of rye, potatoes, mangolds, turnips,

Crop.		Without sand	With 5.2 cm. of sand	With 10.4 cm. of sand
Rye	grain	14	14.3	14.8
	straw	40.1	40.1	38.1
Leguminosae	seed	8.9	15.3	18.6
	straw	21.5	24.7	24.8
Potatoes (tubers)		287 (dry matter 68.3)	273 (dry matter 65.2)	270 (dry matter 65.1
Mangolds		362 (» » 40.9)	350 (» » 41)	343 (» » 40.7
Turnips		273 (» » 40.4)	263 (» » 40.8)	244 (» » 58.3
Fodder oats	grain	14.4	16.4	16.3
	straw	31.7	29.7	29.4
	hay	14.7	18.0	19.4
Clover with fodder grasses	1st year	60 5	80.5	90.6
	2nd »	45.1	59.9	65.0
	3rd »	44.6	54.3	55.5
	4th »	32.3	38.4	38.8

and, up to a certain point, oats, diminished considerably. But afterwards except in the case of potatoes, the crops were heavier on the soil improve with sand than on the untreated peat land. The averages of all the ex periments show that, as a matter of fact, rye is not influenced by th sand, while potatoes yield the maximum crop in the untreated soil an the minimum crop in the soil that receives most sand. Mangolds an turnips give a slightly decreased crop in the sanded land, but the yiel in dry matter is approximately the same as that on the improved soi Oats yield more grain and less straw on the sanded than on the untreate land, the quantity of sand used having little or no influence. On th contrary, the leguminous plants and fodder grasses usually gave a constan increase of yield with an increase in the amount of sand applied. If th results of the rotation employed are calculated in "forage units" (1 f rage unit = 1 kg. of grain, 1 kg. of dry matter from root crops, 2.5 k of hay, or 5 kg. of straw), the annual yield per hectare would be:—

2540 forage units on the land without sand
2882 » » » » » with 5.2 cm. of sand
3011 » » » » » with 10.4 cm. of sand

Manuring experiments carried out with the following amounts (quintals per hectare and per year): — 1) 45.3 farmyard manure + 4.5 kainit + 0.91 basic slag; 2) 5.89 kainit + 1.81 basic slag + 1.36 nitra of soda; 3) 8.84 kainit + 2.72 basic slag + 1.36 nitrate of soda; woul give with the rotation quoted above, the following respective numbers forage units per hectare; —1) 2607; 2) 2820; 3) 3006.

392 – **The Antwerp Market for Fertilisers and Other Products Useful to Agricultu from 1914-1919.** — *Les Mercuriales Agricoles*, Vol IV, 2nd Series, No. 1, pp. 1. Antwerp, January 2, 1920.

The appended table gives the prices in July, 1914, and the maxim and minima reached in 1919, at Antwerp for the chief products usefl to agriculture.

Names of the products	Price in July, 1914	Price in 1919	
		Minima	Maxima
	francs	francs	francs
Chili nitre . . . . . per 100 kg.	23.00	58.50	93.00
Sulphate of ammonia . . . . . » » »	28.00	80.00	145.00
Cyanamide 15 % . . . . . » » »	22.65	52.00	65.00
Superphosphate . . . . . per unit	0.335	1.47	1.60
Phosphate slag . . . . . » »	0.25	0.80 (paper bag)	1.60 (paper bag)
Kainit . . . . . per 100 kg.	2.65	7.00	7.00
Potassium Chloride . . . . . » » »	18.00	37.50	37.00
Ammonia (crude) . . . . . per unit	1.00	4.50	Price at end of Dec. 1919
Dried ground blood . . . . . » »	2.10	10.00	
Wool refuse . . . . . » »	0.90	4.00	
Roasted horn . . . . . » »	2.05	6.00	
Leather powder . . . . . » »	1.45	6.50	
Fish meal . . . . . » »	2.20	10.00	
Green bone meal . . . . . per 100 kg.	13.00	42.50	
Phosphated gypsum . . . . . » » «	1.60	3.50	
Copper sulphate . . . . . » » »	56.00	150.00	
Iron sulphate . . . . . » » »	5.25	22.00	24.00
Linseed cake (P. W.) . . . . . » » »	20.25	70.00	102.00
Linseed cake (native) . . . . . » » »	21.00	70.00	90.00
Coconut cake . . . . . » » »	22.50	65.00	75.00
Groundnut cake . . . . . » » »	20.75	60.00	80.00
Rape cake . . . . . » » »	12.75	40.00	50.00
Maize cake . . . . . » » »	15.75	60.00	80.00

Without exception, the prices of all these products have reached a level that would have been thought impossible. Though this enormous increase is due to various causes, these have arisen, directly or indirectly, out of the war. As long they continue in this way, the situation will remain unchanged and only one of the many remedies suggested is of real utility, and that is, increased production.

393 – **Productions and Distribution of Tunisian and Algerian Phosphates in 1920.** — I. Les exploitations phosphatières françaises in *L'Engrais*, Year XXXV, No. 1, p. 29. Lille, January 9, 1920. — II. Phosphates, *Ibid.*, No. 2, p. 57. January 23, 1920.

An agreement has apparently been made between the chief phosphate companies and the French Government fixing the minimum quantities to be produced by each company in 1920. The distribution is as follows:— Gafsa phosphates, 1 050 000 metric tons; Tunisian phosphates, 400 000 m. tons; Constantine phosphates, 350 000 m. tons; Dry phosphates, 100 000 m. tons; M'Zaïta phosphates, 40 000 m. tons; other phosphates, 100 000 m. tons.

It is estimated that, in 1920, Algeria and Tunisia could produce some 1 400 000 metric tons of phosphate, which will be distributed as far as possible in the following way:—

France	700 000 tons	Belgium	4 000 tons
England	247 000 »	Switzerland	5 000 »
Italy	355 000 »	Spain	74 000 »
Portugal	15 000 »		

The total amount of phosphates that it is hoped will be imported during 1920 is 2 600 000 tons, including the quantities listed above, will be distributed as follows :—

France	1 000 000 tons	Holland	100 000 tons
Italy	600 000 »	Portugal	50 000 »
England	400 000 »	Scandinavia	40 000 »
Spain	200 000 »	Switzerland	10 000 »
Belgium	100 000 »		

394 – **The Influence of Green Manures on the Physico-Mechanical Conditions and Aeration of Rice-Fields.** — See No. 417 of this *Review*.

395 – **The Nitrate of Soda Situation in Europe, the United States, and Egypt.** — *Le Mercuriales Agricoles*, Vol. IV, 2nd. Series, Nos. 3, 4, pp. 10, 13-14. Antwerp, January 16 and 23, 1920.

The consumption of nitrate of soda in the different countries in 1919 and the stocks in hand on December 31, 1919 were:—

COUNTRIES	Consumption in 1919	Stocks in hand on December 31, 1919
	metric tons	metric tons
England	48.000	31.000
Egypt	51.000	—
France	172.000	41.500
Belgium	63.000	24.300
Italy	20.000	—
Spain and Portugal	58.000	9.000
Holland	153.000	6.000
Scandinavia	88.000	5.000
Germany	—	5.000
Totals	**653.000** tons	**122.000** tons

It is stated, on good authority, that, in 1920, Spain, Japan, Scandinavia and Holland will receive quantities of nitrate that are considerably higher those taken before the war, and that there is no uncertainty as to the consumption of the nitrate. The United States, France, Belgium, Egypt and Italy will also receive large quantities of nitrate, but it is predicted that the demand will exceed the supply.

396 – **The Influence of Sulphates on the Vegetative Growth and Composition of Plants** MILLER, H. G., in the *Journal of Agricultural Research*, Vol. VIII, No. 3, pp. 87-102 + 4 Plates + Bibliography of 26 Publications. Washington, 1919.

The author summarises previous work on the oxidation of sulphur in the soil and the influence of the resulting products on : *a*) vegetative growth ; *b*) the development of the bacteria and their activity ; *c*) the liberation of other food material for the plants. On account of the good effect of fertilisers containing sulphur found in Oregon, the author undertook some greenhouse experiments in order to study the effect of sulphur on the early growth and the composition of plants, and to ascertain whether sulphur acts directly on plants by furnishing them with food or in some other way.

The pot experiments were carried out with clover, rape and oats in two loams and a clay soil; one of the loams was very rich in sulphur. At the beginning of the experiment, sulphur and lime were applied to the pots, which were watered each day with solutions of various strengths of calcium sulphate and sodium sulphate. A similar series of experiments was conducted in sand to which ferrous extracts had been added. Finally, all the pots were watered every day with a solution of sodium nitrate, so as to prevent nitrogen from being a limiting factor. The experiments lasted 2 ½ months, when the dry weight of the green parts was determined as well as, in most cases, the total sulphur and nitrogen.

It was found that, in the series of pots with earth and those with sand, the sulphur led to increased growth, thus showing that the sulphates and free sulphur had a direct fertilising action: again, the sulphates produce increased growth of the roots and the formation of nodules in the clover grown in soil, thus increasing the nitrogen content of that plant.

397 – **Sulphur as a Fertiliser for Lucerne in South Oregon. U. S. A.** — Reimer, F. C.' and Tartar, H. V., in the *Oregon Agricultural College Experiment Station, Bulletin* No. 163, p. 40 + 9 Figs. Bibliography of 11 works. Corwallis, Oregon, 1919.

Recent American researches have shown that leguminous plants, particularly clover and lucerne, require, in order to give their maximum production, a larger quantity of sulphur than is indicated by analytical data. General manuring experiments carried out in South Oregon in 1912 and 1913, showed that superphosphate and gypsum had a beneficial effect on lucerne, which showed a deeper colour, whereas natural phosphate had no effect. In addition, it has been found that lucerne, clover, *Pisum arvense* and the vetch develop better and show a deeper colour when growing under trees treated with lime-sulphur wash than elsewhere.

Experiments were started in 1914, in a medium soil, in order to compare superphosphate, flowers of sulphur, crude phosphate, and sulphate of iron at the rate of 560 kg. per hectare. Compared with the controls, the sulphur, superphosphate and sulphate of iron gave increases in yield of over 100 %, while the natural phosphate had no action.

In further experiments carried out from 1915-1918 on different types of soil (clay, clay loam, sandy loam, gravel), lucerne and clover showed increases ranging from 50-1000 %, owing to the use of various fertilisers containing sulphur (flowers of sulphur, superphosphate, gypsum, sulphates of iron, ammonium, potassium, magnesium and sodium), in all the soils from coarse granitic to the most compact clay soils. Yet the application to the same soils of nitrate of soda, monocalcium phosphate, potassium chloride and lime, had little or no effect on lucerne. It thus would appear that the beneficial action of the fertilisers containing sulphur, mentioned above, is due neither to the liberation of phosphorus, potassium or lime in the soil, nor to nitrification, particularly as the experimental soils were rich in potassium, calcium, magnesium and iron, while they had a low sulphur content, although they were not acid, and contained appreciable amount of no alkaline substances.

When flowers of sulphur are applied to the soil, they must be changed to sulphates before the lucerne can make use of them. This requires a certain time, so that better results are obtained when the sulphur is applied in autumn rather than in spring. During the first year, the gypsum and other sulphur materials gave better results than flowers of sulphur, though they were all given in equal amounts ; but, in the second year, there was little difference between the crops obtained.

The different sulphur fertilisers have a very stimulating effect on the root system of lucerne, which is more developed and possesses more nodules. This is a great advantage as the plant can assimilate more food elements, moisture and atmospheric nitrogen. The analysis of plants treated in the way showed that they contained more sulphur, protein and nitrogen than untreated plants. Lucerne hay from South Oregon contains more sulphur that of the west-central States, and the sulphur content of manured lucerne hay varied from 1.5 to 4.54 lb. per ton, while, in the unmanured plots, it was from 2.36 to 2.54 lb. ; 71-97 % of the sulphur in the lucerne of the treated plots is present in an organic form, and the rest as sulphate ; with the untreated plots all the sulphur in the hay is present in an organic form.

For the district in question, the manuring advised per hectare consists of 200 lb., of gypsum, or 254 lb., of superphosphate, or 45-50 lb., of sulphur with 200 lb., of natural phosphate ; the last combination is the cheapest. It should be remembered that sulphur cannot be applied to soils poor in lime, as it causes acidity in the soil ; in this case, the sulphur should be given only with large dressings of lime or natural phosphate.

AGRICULTURAL BOTANY. CHEMISTRY AND PHYSIOLOGY OF PLANTS

398 – **Correlation Between the Resistance of the Plant to Low Temperatures and the Density of the Cell Sap.** — EARL, S. J., in the *American Journal of Botany*, Vol. VI, No. 9, pp. 373-379 + 2 Fig. Lancaster, Pa., November, 1919.

For the fruit grower the effect of external agents in relation to the resistance of the peach tree to low temperatures constitutes a very important problem which cannot be properly solved until empiric observation is reduced to a minimum and replaced by some sure and accurate physical or chemical measurement. Once such a measuring unit is found, a careful determination should be made of the action of external agents with regard to the degree of resistance of different varieties growing under similar environmental conditions.

OHLWEILER, CHANDLER and other workers have shown the existence of a positive correlation between the resistance of the plant to low temperatures and the density of the cell sap, a correlation due to the lowering of the freezing point. It is obvious that, in carrying out such a determination, very important factors have to be neglected, as, for example, the shape and size of the cells and the presence of colloids. The shape and size of the capillary network depends on the size and shape of the cells, and the capacity of retaining a varying amount of water depends on the quantity of colloids present. Such phenomena undoubtedly influence the resistance of the tissues.

SALMON and FLEMING state that there is no relation between the cryoscopic value (depression of the freezing point) of the sap extracted from

winter rye, from wheat, emmer, barley, and oats, and the resistance to low temperatures. These contradictory statements are due to the omission of important factors such as capillarity, etc.

Beach and Allen have reported a relation between the resistance to cold and the water content of the tissues, as the parts of the plant richest in water are also the most tender and least resistant.

The author carried out a series of experiments during winter, 1918-1919, in order to find whether the moisture content of the fruit buds of two varieties of peach one sensitive and the other resistant to cold, is so different as to furnish an explanation of the different power of resistance to low temperatures. The two varieties Elberta (slightly resistant) and Greensboro (very resistant) were used, and samples, first taken on November 8, 1918, were procured every month.

Each sample consisted of 10 fruit buds, and after their weight had been found, they were placed in an electric autoclave and dried at approximately 82°C. until a constant weight had been reached. After 12-18 hours, the dry weight was determined. The following table includes data showing *a*) the seasonal variation in the green weight and dry weight; *b*) the relation between the water content and the green weight; *c*) the relation between the water content and the dry weight. The dry and green weights each represent an average of 10 determinations.

Dates	Average Green weight in gm.		Average Dry weight in gm.		Ratio between water content and green weight		Ratio between water content and dry weight	
	Elberta	Greensboro	Elberta	Greensboro	Elberta	Greensboro	Elberta	Greensboro
November. 8	0.124	0.121	0.073	0.073	0.41	0.40	0.69	0.65
December. 6	0.144	0.129	0.079	0.073	0.46	0.43	0.84	0.76
January 7	0.144	0.123	0.082	0.075	0.43	0.38	0.76	0.62
February 7	0.164	0.128	0.082	0.075	0.49	0.42	0.99	0 71
March 7	0.327	0.220	0.115	0.092	0.65	0.58	1.85	1.37
March 28	1.050	0.750	0.205	0.160	0.80	0.76	4.12	3.17

The seasonal variations of the dry weight are very small compared with those of the green weight, the increase of which is due to the water. It is interesting to note that the water content in relation to both dry and green weight is always greater in the case of Elberta than in that of Greensboro, a variety which is more resistant to low temperatures in almost every case.

399 – **Researches on the Flowering and Fertilisation of the Wheat Flowers, in the U. S. A.** — Leighty, C. E. and Hutcheson, T. B., in the *Journal of the American Society of Agronomy*, Vol. XI, No. 4, pp. 143-162 + 2 Figs. Washington, April 30, 1919.

Observations made at the Minnesota Agricultural Experiment Station at Saint Paul and on the Arlington (Virginia) Experimental farm, during the summer of 1914, on the flowering time of different varieties of wheat,

and on the fertilisation of emasculated wheat flowers left without protection from heterogamous pollinisation. The varieties examined at flowering time were: 1) Velvet Chaff, Haynes Bluestem, Glyndon Fife, Kubanka, Arnautka, Kharkov, Turkey (at St. Paul); 2) Dietz, Fultz, Mealy, Giant Squarehead, Turkey, Bluestem, and Fife (at Arlington). Each ear was marked, the flowering of each flower was noted, and the data thus obtained shown on a diagram. The observations were usually made at 7a. m., at noon, and from 5-6 p. m. A flower was considered to be in bloom when the glumes had opened to an appreciable extent.

It was found that the flowering of a wheat flower was a very rapid process. After the moment when the glumes begin to open, they may be fully open in less than a minute; the anthers may be extruded and emptied of pollen in 2 or 3 minutes; the glumes may be half-closed again in 5 minutes, loosely closed in 10 and tightly closed in 20 minutes. The entire process, from the first moment when the glumes begin to open to that when they are again tightly closed, seldom requires more than 20 minutes.

More frequent observations were made at Arlington on 25 wheat ears, betwen 4 p. m. on May 26 and 8 p. m. on May 30, and on ten other ears between 2 p.m. on June 1 and 3 p. m. on June 5. Although flowering takes place at any hour of the day, it is most intense at fairly well-defined periods.

The flowering dates of 2977 flowers on 69 ears were recorded: 1492 flowered between 5 or 6 p. m. and 7 or 8 a. m., and 1485 flowered in the daytime. Of the latter, 764 flowered before noon. At St. Paul 70 more flowers flowered at night than in the day; at Arlington 63 flowered more in the day than at night. The hour of flowering apparently depends, up to a certain point, on the variety, although this is not considered by the authors to be the most important factor. In daytime, there are two periods of intense flowering, one between 7-9 a. m., and the other between 2 or 3-4 p. m. In the morning, at about 11 a. m., there may be a secondary flowering period. There is probably at least one period of intensive flowering during the night or early morning hours. The time between the beginning and end of the flowering of an ear varies between 2 and 7, with an average of 3 days. Therefore it is not true that wheat always flowers in the early morning hours and that, in consequence, the opening anthers should be collected at that moment.

The flowers on a number of ears belonging to different varieties were emasculated before their pollen was ripe and no protecting envelope was given, whereas at St. Paul the flowers belonging to ears all of the same variety. were treated in the same way, but covered with soft tissue paper and at Arlington they were placed in paraffined (glassine) paper bags. The varieties used for this experiment in Minnesota were Kharkov, Red Fife, Haynes Bluestem, Velvet Chaff, Glyndon Fife, Kubanka, Arnautka, and, at Arlington, Fultz, Lancaster, C. I. Nos. 3614, 1733 and 1933, Tennessee Fultz, China, Early Genesse Giant, Acme, (Sel. II), Kanred. At St. Paul, the following results were obtained: out of 70 ears emasculated and left uncovered, 1240 flowers gave kernels from 507; out of the emasculated and covered ears, 388

flowers hardly formed 2 kernels; out of the emasculated, pollinated and bagged, 41.7 % of the flowers formed seeds. At Arlington, out of 1324 flowers belonging to 83 ears (emasculated and left uncovered), 1103 formed kernels; out of 642 flowers of 40 emasculated and covered in, only 6 kernels were formed, 3 of which were on ears contained in bags that had been torn.

When wheat flowers are emasculated and not pollinated, the glumes apparently open a little after the usual flowering date and remain open several days; the style grows to an abnormal length, thus facilitating the entry of the pollen. On the contrary, the glumes remain closed when pollination has taken place. Successful fertilisation of *all* the flowers polljnated by hand is quite exceptional. The unfertilised flowers, which often amount to 50 % or more of the pollinated flowers, remain with open glumes, so that some, at any rate, may possibly be fertilised by pollen from other plants.

These results show that, when studying the heredity of wheat hybrids and in operations of crossing when it is desired to obtain hybrids of known parentage, the emasculated flowers must be protected from chance pollination. The opinion to the contrary held by various workers seems, therefore, unjustifiable.

400 – **On the Chlorophyll Production of Plants Exposed to Discountinuous Light.** — Coupin H., in the *Comptes rendus de l'Académie des Sciences*, Vol. CLXX, No. 7, pp. 403-405. Paris, February 16, 1920.

Plants grown in complete darkness are usually pale yellow (etiolated) whilst the same plants grown in daylight are green, owing to chlorophyll formation in some of the cell plastids. The explanation of the appearance of the chlorophyll, in spite of a considerable amount of research, is as yet not completely known. The author, therefore, endeavoured to ascertain, as a contributing factor, the length of time the plants must be exposed, each day, to daylight for the chlorophyll to begin to show. The method employed naturally consisted in growing the young plants in the dark, then exposing them for a varying period during a number of days that varied according to species experimented with diffused, north daylight, until the yellow parts began to assume a slight green tinge, thus showing that chlorophyll was beginning to be formed. The author's results are given in a table; they are, for various reasons (variation of the intensity of the light, difficulty in matching the shade, etc.), approximate only. The conclusions drawn are given below:

1) The time the plants must be exposed each day to the light so that the chlorophyll begins to appear, varies greatly with different species since the appearance of the green tinge under discontinuous lighting may take from 2 (garden cress) to 20 days (peas); from 20 minutes (sun) to 120 minutes (maize) per day; from 25 minutes (pumpkin) to a total of 2400 minutes (peas).

2) The parts that contain abundant reserve materials (cotyledons of pumpkin, white lupin, lucerne, chicory, etc.) in their tissues, rapidly turn green.

3) The parts that turn green more slowly contain little or no reserve material (leaves of pea, wheat, maize; cotyledons of castor oil plant, etc.).

In order to avoid any possible misunderstanding, the author adds that the green tinge in question is very pale and thus quite different from the green of plants grown naturally and exposed to all the daylight.

401 - **The Causes of the Elongation of the Stem of Etiolated Plants.** — COUPIN H., in the *Comptes rendus de l'Académie des Sciences*, Vol. CLXX, No. 3, pp. 181-191. Paris January 19, 1920.

When a comparison is made between young plants, some grown in the dark, others in the light, the aerial parts of the latter group are green and short, whilst in the former group they are yellow or whitish in appearance and have very long stems.

This difference is generally explained by the fact that light is known to slow down growth. On examining the question more closely, it will be seen that, if light has this slowing-down effect, it could not possibly cause such great differences as those found with certain plants, such as the pea, vetch, lentil, etc., in which the etiolated stems are sometimes 10 times as long as those that have grown in the light. Evidently, there is some other factor acting as well as light. It may be asked whether the characters of etiolated plants are not due to the absence of chlorophyll and consequently, of its activity. Starting from this hypothesis, which was supported by various observations, the author carried out several experiments which apparently confirmed it satisfactorily, without, however, proving its truth.

CONCLUSIONS. — If plants grown in the light are dwarf compared with those grown in dark, this is probably due to the chlorophyll function which, by means of the chloroleucites, distributes in the plant an internal secretion which slows down growth. The author has no information as to the chemical nature of this hypothetical, probably complex substance; he can only say that it is soluble in water and not destroyed by heating to 120°C. Inversely, if etiolated plants have long stems this is because they cannot assimilate, for the double reason that they have no chloroleucites and receive no light rays.

402 – **Action of Chlorine and Different Vapours on Plants.** — GUÈRIN, P. and LORMAND, C., in the *Comptes rendus de l'Académie des Sciences*, Vol CLXX, No. 7 (February 16, 1920), pp. 401-403. Paris 1920.

From their experiments on leafy branches and particularly plants in pots, the authors concluded that most plants kept for one, occasionally 2, hours, in an atmosphere with a concentration of $^1/_{2000}$ of chlorine, palite (monochlormethyl chloroformiate), bromacetone, chloropicrin, or dichlorethyl sulphide resist the action of these substances. They lose their leaves, but new ones grow after a time, and the plant regains normal growth. The leaves are killed by plasmolysis, i. e., by protoplasmic contraction, and this takes place very rapidly with chlorine and very slowly with dichlorethyl sulphide.

403 – **Antagonistic Reactions and the Rôle of the Callus in Grafted Plants.** — DANIEL, L., in the *Comptes rendus de l'Académie des Sciences*, Vol. CLXX, No. 5, pp. 285-287. Paris, February 2, 1920

More and more accurate evidence tends to show that the callus formed at point of union of the graft largely contributes to modify the biological status of scion and stock and to cause a marked antagonism even in grafts of the plant on itself, where, without it, such would not be the case. The antagonism leads to the formation of repairing organs, while the exchange of products accidentally causes various symbiomorphoses. The internal or external repairing organs may be of the pure, associate type or bring about graft hybrids produced directly on the level of the callus or at variable distances away from it.

These products are of immediate practical value. Thus, the Bronvaux medlar and *Pirocydonia Winkleri* are now used as ornamental plants; *Pirocydonia Danieli* will probably play the same rôle in fruit growing with the pear as paradise stock with the apple; in vinegrowing, graft hybrids have already proved there utility, and all their possibilities are not exhausted. There is, therefore, every reason for investigation in this new direction.

404 – **Action of Heat on Sugar-Beet Seed.** — SAILLARD (communicated by M. TISSERAND), in the *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. VI, No. 5, pp. 91-92. Paris, February 4, 1920. AGRICULTURAL SEEDS

M. TISSERAND has communicated to the Academy a note by M. SAILLARD (Director of the Laboratory of the Syndicate of Sugar Manufacturers on the experiments he carried out with M. VEHRUNG as his co-worker on the action of heat on sugar-beet seeds.

The work was done with seeds of very good, good, and medium quality, which were heated in a thermo-regulated oven, while the germination tests were made on damp sand kept at 25°C.

The seeds of each quality were respectively heated for an hour to 40°, 50°, 60°, 70°, 80°, 90°, 100°, and 105° C., then germinated at 25°C. for 22 days together with unheated, control seeds.

The following conclusions were arrived at:

1) The seed clusters of the very good seeds with a 98 % germination, and good commercial seeds with an 87 % germination, retain all their germination power when heated to 60°-70° C., as demonstrated by M. SCHRIBAUX.

2) Bad seeds with a 36 % germination, when submitted to the same temperatures, are mostly killed.

3) A temperature of 80°C., even when maintained for 1 hour; does not alter the germination coefficients after 14 days with superior quality and good, ordinary quality seeds. It only retarded germination slightly.

These experiments will be of interest to those taking part in the competition opened by the French Ministry of Agriculture for the construction of a drying apparatus for beet seed that will enable them to be kept a long time, while leaving their germinating power unimpaired.

405 – **Means for Increasing the Germinating Capacity of Camphor Seeds.** — See No. 426 of this *Review*.

PLANT BREEDING

406 – **The Need for Extending and Intensifying the Line Breeding of Wheat in Spain.** — HERRERA D. J., in the *Boletin de la Asociacion Agricultores de España*. Year XI, No. 117, pp. 90-95. Madrid, February, 1919.

After showing the insufficiency of mechanical selection, the author points out the need for intensifying line breeding in order to create types especially suited to Castille. In that country, the chief quality of wheat should be resistance to drought, as this often occurs after sowing. Such selection, according to the author should be limited to the choice and isolation of a few plants that have shown a clearly super-normal resistance in particularly arid soils or in very dry years. The progeny of these plants should be kept separate, and the various pure lines should be submitted to comparative tests so as to show which lines combine the characters "specific productivity" and "resistance to drought" in the best proportions, while giving the largest yields.

407 – **Correlations Between Certain Characters of the Ear and the Yield of Grain in Maize.** — BRIGGS, H. H., in the *Journal of the American Society of Agronomy*, Vol. XI, No. 6, pp. 230-234. Washington, September, 1919.

The five Selections 77, 120, 119, 133 and 204 were studied. Data concerning the weight and length of the ears, the numbers of rows of kernels and the shelling percentage are given in the following table:

Variety	Weight of ear in gm.	Length of ear in inches	Number of rows	Shelling Percentage
Selection 77	324	8.4	14.6	86.2 %
Selection 120	347	8.8	12.7	85.6
Selection 119	363	8.9	16.8	83.5
Selection 133	218	7.1	15.3	81.9
Selection 204	257	8.0	17.3	83.4

The biometrical data was collected from 1914 to 1918.

As a general conclusion drawn from the measurements made, a constantly positive correlation was found (except in Selection 204 in 1917) between the weight of the ear and the yield. The coefficient varies from + 0.7 to + 0.365 and is, thus, low on the average. There is also a positive correlation between the length of the ear and the yield, but in this case also, there are fairly low values, ranging from + 0.01 to + 0.381; the coefficient, however, is always positive.

Some data regarding the variety Selection 119 are given below:

Year	Average length		Coefficients Correlation	Increase in grain yield due to the greater length	
	Long ears	Short ears		Percentage	Bushels
	inches	inches			
1915	8.8	7.6	+ 0.251	4.0 %	2.00
1916	9.8	8.9	+ 0.354	7.1 »	3.55
1917	9.9	8.4	+ 0.330	16.7 »	8.35

There was no special relation between the percentage of seeds and the number of rows.

408 – **Determination of the Percentage of Cross Pollination Between the White and Yellow Varieties of Sorghum.** — KARPER, R. E. and CONNER, A. B., in the *Journal of the American Society of Agronomy*, Vol. XI, No. 6, pp. 257-269. Washington, September, 1919.

Cross pollination is fairly common in fields of sorghum and militates against the retention and improvement of the selected types. The results are given of a series of experiments intended to establish the proportion of cross pollination under natural conditions.

Cross fertilisation observed in the progeny of white milo, growing under the best possible conditions affording maximum natural cross pollination from yellow milo.

Number of the line	Total number of progeny	Number of plants *with* yellow inflorescences	Number of plants hybrid *without* yellow inflorescences	Total number of hybrids	Percentage of cross fertilisation
1	330	10	—	10	3.03 %
3	184	21	—	21	11.41
4	154	14	1	15	9.74
11	457	13	—	13	2.84
15	70	18	7	25	35.71
23	481	27	1	28	5.82
26	990	40	2	42	4.24
30	509	12	—	12	2.35
37	153	26	2	28	18.30
41	585	39	16	55	9.40
All rows. . .	13430	788	42	830	6.18

In 1917, the author observed a certain number of white milo plants growing in a field of yellow milo. The seeds from 41 infloresences of white milo were sown separately and a total was obtained of 13,430 progeny (see Table), of which only 830 or 6.18 % show hybrid characters.

The hybridisation percentage for white plants completely enclosed in a yellow population is thus slightly over 6%. In the case of two varieties that flower simultaneously, not mixed, but sown on two adjacent plots, the percentage of cross-fertilisation could not be higher than 3%.

409 – **The Improvement of Cereals, Flax and Rye-Grass in Ireland, by Selection and Hybridisation.** — *Report of the Work of the Plant Breeding Division for* 1919, in the *Department of Agriculture and Technical Instruction for Ireland*, Vol. XX, No. 1, pp. 102 107. Dublin, 1919.

Results of selection and hybridisation work undertaken in Ireland, especially with wheat, barley, oats, flax and rye-grass.

METHOD. — First of all, those plants that showed superior characters were isolated (selection by pure lines); the progeny — mother plants, heads of lines, etc. — were grown separately and carefully examined in order to choose the best of the pure lines. Finally, the best lines were multiplied and, after a period of comparative tests, then multipied commercially, when the seed was sold to the farmers.

Besides this selection work, crossings were made between lines considered to be best suited for the creation of new varieties combining the good qualities, while eliminating the bad qualities, of the parents.

WHEAT. — Comparative tests were undertaken at the Albert Agricultural College, at Glasnevin, with the following varieties:

Yeoman, a red wheat recently introduced by Prof. BIFFEN (of Cambridge University). It was produced by crossing the high-yielding Browick Red and Red Fife, which gives good results on milling.

Hawk, red bearded; introduced in autumn, 1918; ripens rather late and is difficult to thresh.

Red Velvet, native Irish; grown in Tipperary.

Queen Wilhelmina, *White Stand-up* (both white) and *Squarehead Master* (red), all widely grown in Ireland.

Cone, produces very coarse seed, ripens late; to obtain good results it must be sown in September or in early October.

Red Fife, not a heavy cropper, but excellent for milling.

Benefactor, white, with felted and very dense ears, very subject to rust.

As regards yields of grain, they come in the following order:— *Yeoman*, *Hawk*, *Red Velvet*, *Queen Wilhelmina*, *White Stand-up*, *Squarehead Master*, *Cone*, *Red Fife*, and *Benefactor*.

BARLEY. — A large number of comparative cultural tests were carried out with *Archer*, *Goldthorpe* and with the crosses *Archer* × *Spratt* $\frac{37}{6}$ 37 and *Archer* × *Goldthorpe* $\frac{4}{5}$ 1

The best results were obtained with *Archer* × *Spratt* $\frac{37}{6}$ (widely grown on account of its evident superiority to *Archer*), both as regards yield and strength of straw.

Archer × *Goldthorpe* $\frac{4}{5}$ 1 has a wide ear, short, stiff straw and a very short " neck ". Although it gave lower yields than *Archer* in all the experiments, it should not be set aside, as it gives good results where very strong straw is required. The hybrid *Goldthorpe* × *Spratt*, although free from the serious defect of *Goldthorpe*, the ear of which falls very easily when ripe, is not yet as productive, and thus leaves the way free for further improvement by means of suitable crossings.

OATS. — Pure line cultivations were made with *Abundance*, *Potato*, *Banner*, *Victory*, *Sandy*, *Island Magee*, *Black Tartary*, *Black Bell*, and *Black*

Mogul. New forms were obtained from the crosses *Black Tartary* × *Potato*, *Banner* × *Black Tartary*, *Victory* × *Black Mogul* and these are still being studied.

Numerous crosses were made during the last season between *Potato* and other varieties, in order to obtain a new variety having, in addition to the excellent tillering and milling qualities of Potato, stronger straw and an earlier ripening habit.

Flax. — A pure-line selection of the commercial variety Riga was begun in 1911. Plants belonging to different lines and coming from distinct mother plants, were at once found that showed remarkable uniformity in both their anatomical and physiological characters, e. g., tillering, vegetative vigour, resistance to low temperatures, duration of growth period, etc. Of the various lines Nos. 3 and 5 were the best and, accordingly, were propagated at Glasnevin and Ballinacurra.

In the comparative trials, plots sown with Nos. 3 and 5 were clearly better than those with the ordinary, commercial type, thanks to the uniformly equal crop. No. 5 gives a higher yield of fibre and No. 3, though producing slightly less, is more profitable owing to the better quality of its fibre. In 1913, the pure-line selections of Riga were renewed, and it was found that Nos. 2 and 6, still under trial, were apparently superior to Nos. 3 and 5 as regards length of stem.

Rye-grass. — The pure-line selection of commercial varieties of *Lolium italicum* and *L. perenne* has also been undertaken.

410 – **Determination of the Percentage of Cross-Fertilisation Between *Medicago sativa* and *M. falcata*.** — Waldron, L. R., in the *Journal of the American Society of Agronomy*, Vol. XI, No. 6, pp. 259-266. Washington, September, 1919.

Results of researches with the aim of establishing the degree of natural cross fertilisation between alfalfa plants growing close together. The two species *Medicago sativa* (with white or blue flowers with intermediate shades) and *M. falcata* (with yellow flowers) were employed. The hybrid plants are easily distinguished from either parent by the characteristic colour of their flowers.

The two species were sown in a square plot in lines in the following order (a total of 117 plants) : —

o × o × o ×
× o × o × o
o × o × o ×

(o = *Medicago sativa*; × = *M. falcata*).

Flowering took place at the end of June and the pods formed at the beginning of August. At that time, there were found to be 10,041 and 5251 pods on plants of *sativa* and *falcata* respectively, of average growth. The seeds from 85 plants were sown separately. The appended table summarises the data relating to the progeny of the plants themselves.

Quantities of seeds produced by the parent plants and the percentage of hybridisation in the F_1 plants of M. sativa and M. falcata growing together.

Medicago sativa					*Medicago falcata*				
No.	Seeds produced by parent	Number of plants that flowered	Hybrid plants	Percentage of hybrids		Seeds produced by parent	Number of plants that flowered	Hybrids plants	Percentage of hybrids
	Grams.					Grams.	Grams.

11	18.0	79	13	16.46	65	2.9	44	17	38.64
12	27.3	74	4	5.41	66	7.8	74	16	21.62
. . . . .									
36	37.9	82	4	4.88	85	4.2	75	28	37.33
Totals	647.1	2099	157	223.53	—	90.8	1862	795	1170.07
Averages	22.3	—	—	7.48	—	3,2	—	—	42.70

The percentage number of plants with hybrid characters was very low with *M. sativa* and high with *M. falcata*. The explanation of this is that the latter species has fewer flowers and less pollen than the former.

The coefficient of correlation existing betwen the percentage of crossing and the yield of seed has been calculated by the author, and, although it is very low (*M. sativa* = — 0. 14 ± 0.12 ; *M. falcata* = — 0.2 ± 0.12) it is always negative, thus confirming the possibility that this correlation does exist.

411 – **On the Need for the Selection of Turnips in New Zealand, in Order to Obtain a More Uniform Product.** — Bruce, L. E., in *The New Zealand Journal of Agriculture*, Vol. XIX, No. 5, pp. 284-287. Wellington, November, 1919.

From many cultural tests of the Champion, Elephant and Superlative varieties of turnip, it was found that morphological deviations from the type are common, these being found even in specially selected varieties furnished by leading European houses.

It is certain that selection carried out in the New Zealand Experiment Stations would give excellent results. But, if it is to be possible, it is neces-

sary : — 1) to produce pure varieties, which requires the help of specialists ; 2) to have an organisation by means of which the selected types could be propagated and kept pure, which requires Government help.

The following plan should be followed : —

First year : From, the original selection A is obtained the product A_1, which is cultivated at the plant-breeding station for its seed. All inferior or aberrant plants must be rejected.

Second year : The seed from the previous year is divided into two A_2 and B. Lot B is sold to farmers for the production of the seed they require ; Lot A_2 is still cultivated at the plant-breeding station for the production of pure seed. All inferior plants are rejected.

Third year : I) The seed from A_2, is divided into two lots : A_3 and I B ; A_3 is keptat the station in order to continue the type, I B is sold to farmers who undertake to produce the seed only. II) The seed from B $(= B_1)$ is distributed and sold for root production.

Fourth year : I) The seed from A_3 is divided into two lots, of which A_4 serves to preserve the type and 2 B is sold to farmers who undertake to produce seed only. II) The seed from I B is sown and the seed it produces (I B_1) is sold for root production. III) The seed from B_1 $(= B_2)$ is used for ordinary owing.

At present, the seed produced in New Zealand corresponds to B_2 and gives rise to F_4 products that escape the control of selection for successive generations. On this account, it is not to be wondered at if the crop, instead of being uniform, consists of a product mixed with aberrant or degenerate types.

This shows the need for the institution of pure line selection and the author suggests that a special organisation and plant-breeding stations should be provided in New Zealand.

412 - **Degeneration in the Sugar-Beet and its Remedy in Selection.** — Cassel, I., in the *Bulletin de l'Association des Chimistes de Sucrerie et de Distillerie*, Vol. XXXVII, No. 4, pp. 131-140. Paris, October, 1919.

The flowering of the sugar-beet in its first year of growth is equally harmful to the grower, whose crop is reduced, and to the manufacturer as his root cutters wear out more rapidly. This anticipation of the flowering period has been explained by reference to heredity, but this is improbable because the sugar-beet is the product of long and careful selection, during which any suspected plants are rejected.

Commercial seeds come from parents and ancestors that have been rigorously controlled for a relatively long period (8 or 10 years). If heredity is excluded, then the problem of atavism comes in, seeing that cultivated selected plants tend, when the modifying action ceases, to return to the primitive type. In a wild state, beet is an annual plant, and it is only by means of prolonged selection that it has been possible to obtain the cultivated type which, during the first year, can store up the reserves which will enable it to grow and produce seed during the second year.

The tendency of the beet to " bolt " during the first year is, therefore,

probably a sign of reversion to the primitive type and a symptom of degeneration in the selected type.

In considering the causes that favour this process of degeneration, the author suggests that a plant submitted during its early growth to contrary conditions of soil and climate, which diminish its vitality, has a marked tendency to premature flowering. The author illustrates his theory by a number of examples taken from flower and fruit growing.

It is known that beets sown early give a higher percentage of " bolters " than beets sown later (normally). In the second case, the temperature is very high at sowing time, with the results that germination takes place rapidly and is complete in 10 to 12 days. Under these conditions the young plants are healthy and strong, remaining so up to an advanced stage of growth and accumulating large amounts of reserve material without flowering. On the contrary, if they are sown very early, they usually have to face cold and damp weather, germination is delayed, the early growth is weak and slow, and the plant, on the return of favourable growing conditions, tends to close its vegetative cycle prematurely as if, influenced by previous adversity, it feared to meet some new obstacle opposing the final act of reproduction of the species. Having gone so far, it now becomes a question either of abandoning early sowing or of submitting to the losses caused by bolting.

Besides the advantage consisting in the better distribution of the work, early sowing also leads to a greater production of sugar. Plants produced by early sowing, if not too injured by cold during their early growth, have attained, by the season of " second " heat, a development that enables them better to resist drought. In fact, the well developed roots penetrate to depths where the soil has most moisture and provide the plant with sufficient water to compensate for transpiration. If " bolting " can be avoided, the weight of roots and the sugar content will be greater.

The following measures are recommended in order to avoid the bad consequences (bolting) of early sowing : —

1) Decortication of the seed, to facilitate germination.

2) Shallow sowing, to aid emergence.

3) Keep the soil loose the young plants to emerge, without. however, breaking the surface layer up too much, as fine soil easily cakes under rain and thus prevents the young plants from coming up.

4) Avoid premature thinning that would expose the isolated and still tender plants to a return of cold weather.

5) The best method certainly consists in selection and crossing. carried out in such a way as to produce new types that resist cold and consequently capable of growing even under unfavourable conditions of temperature.

413 – **Geographical and Taxonomic Researches undertaken in Order to establish a Rational Basis for the Selection of Tea.** — COHEN, S. C. P., in the *Department van Landbouw Nijverheid en Handel-Lands Planetuin. Bulletin of the Botanical Garden of Buitenzorg*. Vol. I, Pt. 4, pp. 1-320 18 Figs. Buitenzorg, 1919.

After summarising previous work done in Java on the improvement of tea, the author deals with the question of a vast programme of research

which includes a detailed study of the many varieties of tea, the object being the establishment of a sound basis for work from the standpoint of genetics and selection.

The first chapter deals with tea-growing in Java (1) and British India, the second with tea-growing in China and the adjacent countries (especially in Indo-China (2)) the third is concerned with the origin of the tea plant, and the fourth relates to a systematic study of the genera *Camellia* and *Thea*, a genealogical tree and key being given for the identification of the various species. The fifth chapter treats of common tea (for which the author proposes the name of *Camellia theifera* (Griff.) Dyer) ; the following varieties and races, known in India and China, have been described in detail after a careful examination : —

I. — Variety *viridis* Watt. — *Race* 1, *native to Assam* : bush or small shrub with leaves 10-17.5 cm. long and 5-7 cm. wide, with ovate-oblong, pointed, thin almost, membranous blades, and 16 chief veins ; intermediary tissues thin, wrinkled, pale green in colour, highly vascular. The lower surface is rough to the touch owing to the presence of numerous warts (protrusion of the epidermal cells at the base of the hairs). Inflorescence nearly always solitary. Numerous varieties are derived from this race ; it is grown the most and spoken of as the best of all the types of tea in India.

Race 2 : *Lushai*. — In shape resembling a small tree like the poplar and from 50 to 60 ft. high. When full grown, its leaves are, on an average, 20-35 cm. long and 10-15 cm. wide. Of all the known races of tea, this has the largest leaves and, in this respect, it is much superior to the Chinese types. The blades have from 22-24 chief veins ; the structure and characters of the epidermis are the same as those of native Assam tea. *Lushai* is cultivated over small areas in Sylhet and Chittayong and is apparently a local form derived from wild plants.

Race 3 : *Naga*. — Bush with open, upright habit. Mainly grown round Pherima, at an altitude of 1950 ft. Leaves with very elongated blades from 10-22.5 cm. long and 5-7.5 cm. wide. As regards structure it is very similar to Assam tea, with which it is easily crossed, producing numerous hybrid forms.

Race 4 : *Manipur*. Wild tea growing in the Manipur forests. Transported to Cachar, Sylhet and even Annam, it is now grown over a very large area and has often been crossed with other races. Manipur tea is characterised by the width of its almost elliptical leaves : blades 15-20 cm. long, 6.2-8.7 cm. wide. Leathery structure ; dark green colour ; few but evident veins.

Race 5 : *from Burma and the Shan States*. — These are little-known and ill-defined types that form a group blending on the one hand with the

(1) For tea-growing in Java, see *R.*, Feb., 1920, No. 209.

(2) For Indo-Chinese tea, see *R.*, Nov. 1918, No. 1243 ; *R.*, April, 1919, No. 467 ; *R.*, May, 1919, No. 601. and No. 427 of this *Review*. (*Ed.*)

Manipur race and on the other with the Yunnan race. The leaves, clearly elliptical in shape, are smaller and coarser than Manipur leaves.

Race 6 : *Yunnan and China.* — Owing to the lack of data, a classification like that for India cannot be established. Open bush found growing in forest shade, i. e., under the same conditions as true wild tea in India. The leaves are 11-12 cm. long and 4-5 cm. wide.

II. — Variety *bohea.* — Fine-loking bush, much ramified, mostly found in India as a cultivated plant. Leaves of medium size, linear, oblong, thick, coriaceous, smooth, often folded along the length of the upper face (which makes the blades concave instead of convex, as in native Assam). There are 10-15 chief veins ; the lower face of the blade is covered with spots resembling small shining scales.

III. — Variety *stricta.* — Small, much ramified shrub, never over 60 cm. in height. Found frequently at Darjeeling, Kumaon, Kangra, in the Nilghiri Mountains region, in some parts of Upper Assam and even, which is worthy of noting, in China. Small, linear, smooth, thick, coriaceous, leaves, with indistinct network, and 4 chief veins (sometimes 6, rarely 8). Their length varies from 2.5-6 cm, and their breadth from 1 to 2 cm. But, in many cases, the tree as well as its leaves, has smaller dimensions. There is a specimen in the Kew Herbarium which measures in all, roots included some 10-15 cm., in length and the leaves are reduced to 1.25 × 0.60 cm. The same small spots are present on the lower face of the leaves of the variety *stricta* as in the variety *bohea.* This peculiarity, common both to *stricta* and *bohea,* distinguishes them from all the other races of tea and suggest that they are derived from a cross between forms with larger leaves.

IV. — Variety *lasiocalyse.* — Much branched shrub, with abundance of oblong, pointed leaves, cuneiform at their base; dimensions 2.5-5.0 cm. × 1-2 cm. ; thick, large leaves, of a pale lemon colour when dry ; almost glabrous, except for a few trichomae on the lower surface near the central nervure. Compact inflorescences with 3-5 flowers, very short peduncles, and 2-3 bracts ; calyx formed of two whorls of small rounded sepals, more or less hairy, and brilliant red in colour. The author thinks that the variety *lasiocalyse* is derived by mutation from a type with glabrous leaves.

Indian and China tea. — According to the author, Assam tea, discovered in 1835, is more similar to the races from Burma, the Shan States, and Yunnan, than the large-leaved Manipur and Lushai types. The author also mentions the two races of tea, one with small and one with large leaves, discovered by Eberhardt at Tonkin, on the heights of Tani-Dav, and, after reviewing all the types described by Watt, he discusses the value of the species and varieties of *Thea sinensis* described by Linnæus and quoted by Loureir, Salisbury, Von Siebold, Masters, Pierre, and J. Kochs.

A collection of such important, though sometimes ill-defined, mateial offers notable difficulties to classification. According to Watt, there are 2 chief varieties : var. *viridis* Watt, with large, glabrous leaves and var.

lasiocalyse Watt (or var. *pubescens* Pierre), with hairy leaves, rather rare and chiefly known in the peninsula of Malacca. All the other forms and varieties found in the plantations, then, would be derived by crosses between the two fundamental types :

1) *viridis* × *lasiocalyse* = *stricta ?*
2) *viridis* × *stricta* = *bohea.*
3) *viridis* (Manipur) × *stricta* = Ceylon hybrid.

Various forms of leaves of tea in a " population ".

But this interpretation is not completely, satisfactory to the author, who is inclined to believe (see above) that *lasiocalyse* was procuced by mutation from a form with glabrous leaves, Yet, however complicated and difficult the problem of a final classification may be, if the characters of shape and colour are taken as a basis, the existence could not be denied of a substantial and profound difference between the two extremes of small-leaved China tea and large-leaved Indian " Lushai " tea. These two types can be characterised in the following way :—

China tea	*Indian tea*
1) Small shrub.	1) Tree with spreading crown.
2) Early and numerous flowers.	2) Late and scanty flowers.
3) Leaves rarely measure more than 9 × 3 cm.	3) Leaves usually measure more than 12 × 4 cm.
4) 8-10 pairs of lateral nervures.	4) 10-14 pairs (up to 22) of lateral nervures.
5) Usually more than 30 teeth.	5) Usually less than 30 teeth.
6) Leaves generally reddish towards the tip.	6) Leaves usually green or yellowish-green towards the tip.
7) Leaves usually smooth.	7) Leaves often rough.

CULTIVATED TEA. — There is no doubt that there are two distinct races of tea — Chinese and Indian. The difficulty begins when it is attempted to establish the taxonomic position of the intermediate forms, which are also the commonest. Instead of undertaking this apparently unending analysis, the author prefers to group all the cultivated types that furnish " tea " under one species. This apparently is equally satisfactory to practical requirements. In fact, the commercial types are far from belonging to well defined varieties, but they constitute a mixture of forms that are often very different one from another, (see appended illustration) and it will eventually be more satisfactory to distinguish by a statistical method rather than by a botanical classification.

As regards the rules to be applied to the identification of this collective species, the result of the critical examination of the various systems of nomenclature taken into consideration may be summarised as follows : —

1) The generic term *Thea* should be rejected ; *Camellia* is the only correct name.

2) *Thea sinensis* (L.) Sims., is out of date, whereas *Camellia sinensis* (L.) O. K. is in accordance with the international rules ; again the name given by LINNAEUS (1753) does not include Assam tea.

3) *Camellia Thea* (Link) Brandis., should be excluded ; the Indian and Chinese types have already been united under a single species — *C. theifera* (Griffith) Dyer.

4) *C. theifera* should be used in preference to *C. sinensis*.

The author, therefore, proposes to unite all the cultivated forms of tea under the collective species *Camellia theifera* (Griffith) Dyer.

414 - **Improvement of Coffee in India, by Selection and Crossing.** — ANSTEAD, R. D., in *The Agricultural Journal of India*, Vol. XIV, Pt. IV, pp. 639-644. Calcutta, July, 1919.

Since the possibility was shown by CAMERON, in 1899, of considerably improving coffee by selection and hybridisation, much work has been done with the object of forming a new type of ordinary *Coffea arabica*, that would be more productive and disease-resistant.

Good results were obtained in various localities, particularly in South Mysore by CRAWFORD, in Chundrapore by HAMILTON, and in South Coorg by JACKSON ; they succeeded in producing several excellent and completely stable hybrids, whose seeds will shortly be put on the market. The author

points out the need for establishing a special station for the selection of coffee, provided with a special expert staff.

So far, however, this work has not had the slightest influence on the methods of cultivation in use on the plantations. The way the seed destined for the nurseries is gathered, without any attempt at selection, cannot but harm the varieties and lead to their degeneration, as has already been found in several localities in India.

The first principle of selection should be to choose the best tree on the estate, which should be characterised by uniform growth, an abundant and good-quality product, even under unfavourable weather conditions, and by immunity to disease and a high degree of resistance to insect attack.

The best plants chosen in this way should be completely covered by a net at flowering time, to avoid chance fertilisation by strange pollen, the net being held down by earth and strengthened by a border of strong cloth. This isolation ensures self-fertilisation, but decreases the percentage, of seeds set; this difficulty might be avoided by allowing insects such as bees to swarm under net. In any case, the quantity of seed obtained is sufficient for the establishment of nurseries and the method has the advantage of producing plants that completely resemble the parent tree.

As soon as setting has taken place, the net can be removed, and the fruits are removed when completely ripe. The seeds are rigorously selected, and the best ones sown in nurseries; the young plants that result are carefully examined, any weakly or badly developed plants being rejected before transplanting takes place. When these selected plants begin to produce, 3 or 4 of the best are chosen and isolated in the manner described above.

Thus, in 10 or 20 years, simply by selection, vastly improved types can be obtained that are much superior to the original variety. Besides this improvement, on account of the lack of genetic uniformity in the original varieties, which are more like mixtures or populations, stable varieties can be obtained, or rather isolated, that show distinct differences.

As regards crossing, JACKSON obtained a hybrid of *arabica* at Dubarri. This was a true hybrid of very vigorous growth, which is disease-resistant and comes into bearing early (in the second year). In September, 1918, the first plantation (about 23 acres) of this hybrid was made at Malamby; by the end of the first year, the plants were already from 3 to 6 feet in height. The great uniformity, vigorous growth, productivity, and resistance to disease of this hybrid make it a remarkable type, that will certainly be justly esteemed on the market.

415 – **Influence of Foreign Pollen on the Shape of the Fruit of the Mother Plant in Certain Crosses between Vanilla planifolia and "Vanillon".** — MAC CLELLAND, C. B., in the *Journal of Agricultural Research*, Vol. XVI, No. 9, pp. 245-251 + Plates 31-35. Washington, March, 1919.

For some time, experiments have been undertaken at the Mayaguez Agricultural Station with the object of developing the cultivation of vanilla on a large scale at Porto Rico.

Careful studies of pollination, fertilisation, growth, and the characters of the fruit have been, and are still being, made. Two types of vanilla are of economic importance to the island :—

1) *Vanilla planifolia* with thin, elongated pod of excellent quality, and 2) " Vanillon ", thicker shorter pod of very inferior quality, but which, even when quite ripe, can remain attached to the plant without opening, which is of considerable advantage.

The results are given of a series of reciprocal crosses between *V. planifolia* and " Vanillon ", especially as regards the immediate influence of foreign pollen on the shape of the fruit of the mother plant, an influence that can be studied and determined.

The typical self-fertilised fruits of *V. planifolia* are elongated capsules that narrow gradually towards the peduncle, and retain their thickness almost to the tip, which makes them club-shaped.

The name " Vanillon " includes all the varieties or species of vanilla that do not belong to *V. lanifolia* and which are generally characterised by large yellow flowers, whereas *V. planifolia* has greenish-coloured flowers which are not very obvious. Vanillon fruits have a uniform diameter all along their length, save at the ends, where the sudden blunting gives them their truncated, squat appearance.

If the pollen of *V. planifolia* is placed on the stigma of Vanillon and *vice versa*, the fruits obtained are modified, showing the influence of foreign pollen. So as to find the biometric characters of the shape of the fruits, the author measures them in two places : — 1) at a distance of 2.5 cm. from the tip ; 2) at a distance of 3.7 or 2.5 cm. from the base or the insertion of the peduncle.

In the pollination experiments, the author used *V. planifolia* and many varieties of Vanillon, Viz., V 13 from Guadeloupe ; V 34, V 43 and V 52 from Panama ; V 62 from Mexico.

I. — *Vanilla planifolia* ♀ × *V. planifolia* ♂ : the circumference of the fruit at 1 inch. from the base is less than the circumference at 1 $^1/_2$ inches from the tip ; in other words, fruits that are thin at the point of insertion become club-shaped at the tip ; the following averages are based on 23 determinations : —

1) Length of fruits : from 6 $^1/_2$ to 9 $^3/_4$ inches.
2) Average circumference at 1 $^1/_2$ inches from the base : 1.3 inches.
3) Average circumference at 1 inch. from the tip : 1.66 inches.

II. — *V. planifolia* ♀ × Vanillon ♂ : the data for 7 out of the 20 measurements carried out are given in the following table : — (see pag. 449)

The circumference of the fruit, at 1 $^1/_2$ in., from the base, is greater than that at 1 in. from the tip by 25.1 %. The averages from 20 measurements are : —

1) Length of fruits : from 6 $^1/_2$ ins., to 9 $^3/_4$ inches.
2) Average circumference of fruit at 1 $^1/_2$ ins., from base : 1.7 inches.
3) Average circumference at 1 in. from tip : 1.38 inches.

Variety supplying pollen	Length of fruits	Circumference of fruit at 1 ½ ins. from stem end	Circumference of fruit at 1 in. from tip
	inches	inches	inches
V52.	6 1/2	1 56	1.1
V34.	6 3/4	1.6	1.25
V52.	7	1.5	1.1
V62.	7 1/2	1.8	1.3
V34.	8	1.87	1.3
V52.	8 1/2	1.6	1.5
V52.	9	1.8	1.6
Averages for 20 varieties	—	**1.7**	**1.38**

III. — Vanillon ♀ × Vanillon ♂. At 2.5 cm. from the two ends, the fruits have practically the same circumference. The data from 54 measurements are : —

1) Length of fruits : from 3 to 7 1/4 ins.
2) Average circumference at 1 in. from base : 2.46 ins.
3) Average circumference at 1 in. from tip : 2.45 ins.

IV. — Vanillon ♀ × *Vanilla planifolia* ♂ : the circumference at the tip is 28.2 % greater than that at the base ; hence the club shape. The averages from 23 measurements were :—

1) Length of fruits : from 2 3/4 to 5 1/2 ins.
2) Average circumference at 1 in. from base : 2.05 ins.
3) Average circumference at 1 in. from tip : 2.6 ins.

It is evident that foreign pollen modifies the shape of the fruits on the mother plant.

The structure of the flowers of these two types of vanilla offers a plausible explanation for these facts. At flowering time, the ovaries are practically the same length in both types, whereas the style of Vanillon is much longer (from 60-70 %) than that of *V. planifolia*. When the pollen of the latter is placed on the stigma of Vanillon, it can hardly force its pollen tube to the base of the ovary ; in any case, the number of ovules fertilised would be greater towards the tip than at the base of the ovary, hence the club shape of the fruit.

The pollen tubes of Vanillon, when placed on the stigma of *V. planifolia*, have a shorter distance to traverse to reach the ovary than they would ordinarily have in their own flowers, in which the style is longer. A large part of the ovules (placed at the summit of the ovary) of *V. planifolia* would not be fertilised by the Vanillon pollen, whose germination tubes reach the bottom in attempting to reach a point corresponding to the normal distance between the stigma and ovary of Vanillon. There results more abundant fertilisation at the base of the ovary and consequently, the number of seeds diminishes progressively towards the summit, for which reason the fruit gets gradually thinner towards the tip, which is partly empty.

CEREAL AND PULSE CROPS

416 – **Experiments on Wheat Growing in Tonkin.** — MIÉVILLE, R., in the *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 12, pp. 364-369. Saigon, December, 1919.

For some years, wheat growing has been attempted in various parts of Indo-China, especially in Tonkin. The experiments have been carried out on the delta and on plateaux of varying height, but, up till recently, the results have not been very encouraging.

At Trau-Ninh (Tonkin), in 1904, 1905 and 1906, the Agricultural Station situated near Xieng-khouang, at an altitude of about 4000 ft., carried out experiments in growing cereals (wheat, rye, oats, barley), but without satisfactory results. In the first series of experiments, carried out in the rainy season, the following varieties of wheat were grown : — Hard Medeah Spring Saumur, Bordeaux, and Bearded Hérisson. Sown at the end of April (1904 and 1906), or on July 10. (1905), these wheats produced no seed. This failure is due to the special conditions of the climate.

The fairly frequent rains at Trau-ninh did not cause any rotting of the stool of the wheat, but, on the contrary, aided tillering, though at earing time the stems were weak and scanty. Flowering is fatally deficient, as the pollen is washed away by the rain, so that fertilisation is not brought about. This is why the first experiments should have been directed to finding the best times for sowing. On account of these negative results, the experiments were suspended for a long time.

The author took up the work again in the autumn of 1917, with the following varieties: Early Richelle, Red Touzelle de Provence (French wheats), Caobang (Tonkin) and Red Yunnan (China).

The Caobang wheat was sown on November 21-24, 1917; the seed had a poor appearance and a very slight weight. The plants came up on November 27-30, earing took place on February 25, flowering on March 10, and the harvest on May 1. The straw, which was fully grown, was 1.2 metres high and the crop was 90 kg., or 22.5 times the weight of seed used (4 kg.). As may easily be understood, Caobang wheat is far from being genetically pure, but it can be considered as a mixture of different forms. Thus, as regards the characters of the ears, one-third was bearded and two-thirds were not. Tillering was normal and the straw, although weak did not lodge.

The quality of the seed obtained was much better than that of the grain sown, the weight of 100 grains of the former being almost four times that of 100 grains of the latter.

The European wheats did not give such good results as the Caobang wheats, but the experiments did not exclude the possibility of finding, among the very early European wheats, a few types that might do well under the particular climatic conditions of Tonkin.

The author considers that Yunnan wheat is the origin of Caobang wheat, carried to Tonkin by caravans coming from the adjacent Chinese province.

Beside the improvements that could be obtained by selection, the chief object in any case should be to adapt the crop to the climate, and from this point of view, two lessons may be learned from these experiments :—

1) Sow in the second week in August, so that the young plants, profiting by the last rains, can attain a good root development, which in turn assists tillering.

2) In the choice and period of cultivation, as in the creation of types of wheat, care should be taken that the flowering period coincides with a dry spell.

417 – **Green Manures in Old Rice Fields.** — Novelli N., in *Il Giornale di Risicoltura*, Year IX, No. 10, pp. 155-157. Vercelli, October 31, 1919.

As a rule, fertilisers produce an increase of yield in rice fields, but the crop does not always respond completely in old, stable rice fields. Although continually submerged, rice-field soil thus needs special physical and mechanical conditions for it to make best use of the accumulated chemical fertility. This explains the good effect of manuring, even with straw manure, and of green manures. In this case, leguminous green manure with phosphatic fertilisers constitutes the ideal manuring, and the leguminous plant which, owing to its adaptability and its early growth, gives the best results, is crimson clover.

Numerous practical observations carried out under varying conditions have led the author to believe that physical and mechanical conditions of the soil may be much improved by the use of crimson clover as a green manure. In fact, crimson clover, with its rather rigid, strawy, almost siliceous stems, decomposes much more slowly than the other green manures when dug in, and, consequently, its physico-mechanical action on the soil is much more lasting. Again, there is good reason to believe that straw not only leads to a much greater aeration of the soil, but also prolongs it when the soil is submerged.

418 – **Cultural Experiments with *Phaseolus acutifolius* var. *latifolius* in California.** See No. 385 of this *Review*.

419 – **Manurial Experiments with Lucerne in the United States.** — See No. 397 of this *Review*. FORAGE CROPS

420 – **Potato-Growing Experiments in England.** — I. Chittenden, F. J., Effect of "Place" on Yield of Crops in the *Journal of the Royal Horticultural Society*, Vol. XLIV pp. 72-74 + 2 Pl. London, May 1919. — II. Potato Experiments at Wisley, 1917, *Ibid*, Vol. XLIII, Pt. 1, pp. 114-129. May, 1918. — III. Wilson, J. and Chittenden, F. J., Some Further Experiments with Potatoes, *Ibid.*, Vol. XLIV, pp. 83-88. May, 1919.

I. — Effect of "place" on unit yield. — The observations made by the author on some experimental plots at Wisley, England, in the garden of the Royal Horticultural Society, show that the place occupied by a plant is an important factor in the yield of potatoes and should be taken into consideration when the comparative yields from different plots are calculated.

"Up to Date" potatoes were planted in 8 pairs of plots, forming 2 parallel series of 4 pairs, each plot having 3 equidistant lines and containing 18 equidistant plants. The pairs of plots were so arranged that each external line was 4 or 5 feet away from the external line of the adjacent pair.

The two series of plots were sufficiently separated from one another so that the plants at the ends of the internal lines were freely exposed to the sun on one side, while the plants at the ends of the external lines were freely exposed on both sides.

Taking the total production of the internal lines as 100, the average results for the 3 lines on all the plots were 100 : 72 : 72. The yield from the plants on the ends of all the lines compared with the average yield of the other plants of the same line was as 100 : 82. The average yield from the corner plants was as 100 : 66 compared with that of the other plants at the end of the line, as 100 : 79 compared with the other plants of the outside lines, and as 100 : 57 compared with the plants inside the plots.

The conclusion is that the best place is at the outside corners, followed by the outside lines, then the ends of the inside lines, whilst the worst place of all is on the inside lines.

II. — Experiments with potatoes at Wisley in 1917. — Descriptions are given of large-scale trials with varieties resistant to wart disease (*Chrysophlyctis endobiotica*) ; observations on : *a*) the effect of cutting seed tubers ; *b*) the effect of covering the cut surface with various subtances ; *c*) the comparison between the seed tubers whether green or not, with a varying number of sprouts already developed and seed brought straight from the store ; *d*) the effect of planting tubers at different distances and on different dates.

The Aberdeen and Great Scot varieties showed a marked resistance to wart disease.

Splitting the tubers gave a small yield per plant but a much greater yield for a given weight of seed, so that this practice is suitable if little seed is available for planting, or if its price is very high.

Among the substances used to cover the wound made by splitting the seed, so as to avoid loss by evaporation as far as possible, gypsum gave the best results.

The practice consisting in sprouting the tubers before planting gave an increase of crop amounting to 2 tons per acre, as an average of all the varieties tested.

Sprouting in the light was better than in the dark. Two eyes should be left on each tuber. Tubers weighing from 2 to 3 ounces gave much bigger yields than tubers weighing an ounce.

As regards the distance between the drills, the greatest yield per unit of area was obtained with the closest planting.

The best results were obtained with tubers planted close together at the end of April.

III. — New experiments on potatoes. — The authors carried out experiments at Wisley, in 1918, on the effect of the distance, between the plants and the use of seed of various origins on the yield in tubers. The distances used were 18, 24, 30 and 36 inches between the rows and 9, 12, 15 and 18 inches in the drills. It was found that, with the Arran Chief variety, the best spacing was 24 to 30 inches between the rows and 15 inches between the plants.

In the experiments comparing local seed with seed from Scotland o Ireland, it was found that the former gave the best results. Although all the factors of maximum productivity for potatoes are by no means known, yet it is certain that one of the most important factors is the origin of the seed.

421 – **Cultivation of Sisal in Mysore, British India** (1). — CHATTERTON, A., in the *Mysore Economic Journal*, Vol. 5, No. 4, reproduced in the *Tropical Agriculturalist, Journal of the Ceylon Agricultural Society*, Vol. LIII, No. 6, pp. 380-385. Peradeniya, Ceylon, December, 1919. FIBRE CROPS

The author observes that various species of *Agave* grow quite luxuriantly in the State of Mysore. From their leaves are extracted aloes fibres, used for making rope and string, but the industry is a domestic one supplying local needs only. The extraction of the fibre is difficult, as the leaves contain a corrosive juice and the operation is painful. There are machines that extract the fibre, but they are costly and require considerable power to work them, so that they are out of the reach of most cultivators. In addition, it is unfortunate that the species of *Agave* so far introduced into Mysore, where they grow so well give a poor yield of fibre of low commercial value.

Attention is directed to the importance of sisal (*Agave rigida* var. *sisalana*), which is grown over vast areas in Yucutan, Florida, the late German East Africa, etc., and to a certain degree, in various parts of India. This species gives a good yield of a fibre much in request for rope making. Sisal was introduced into Mysore by Mr. RICKETTS, in 1892, since when it has been cultivated over a large area at Lal-Baghe, in Bangalore, from whence large numbers of young plants have been sent to different parts of India. In Mysore, no practical results of importance have resulted from the introduction of this fibre, but a small plantation of it was sucessfully cultivated sometime ago.

In 1914, the author drew attention to the possibilities of Mysore as regards sisal, but his advice was disregarded. Since then, he has paid more attention to sisal growing, with the result that he is more than ever convinced that Mysore has very great possibilities in this connection.

Sisal should only be grown on stony or gravelly soil unsuitable for any other crop. In addition, rich soils lead to an excessive development of the fleshy, succulent parts of the leaves to the detriment of the quality of the fibre. The best fibre is obtained from gravelly limestone soils of medium quality. Fertilisers are not required, and once the plant has taken root, no further attention is needed and the cost of cultivation is negligible. The extraction of the fibre by hand is difficult, but it is easy if special machines are used.

The author, in dealing with the conditions under which sisal grows, states that the chief reasons why the cultivation of this plant has not developed in Mysore are as follows :

(1) Compare the work of Messrs. CHEVALIER and VERNET, on *Agave Cantala* in Indo-China, in *R.*, February, 1920, No. 203. (*Ed.*)

1) Six years are required between planting and harvest.

2) The extraction of the fibre by hand is impossible from the commercial point of view.

3) Mechanical extraction implies working on a large scale and, consequently, necessitates a large capital in machinery and plant.

4) There is no local market for the fibre, and any export order would require large amounts of this material.

But similar objections hampered the development of tea and coffee growing, and the establishment of the tea industry in India was largely due to Government efforts. The tea and coffee industry were, and still are, controlled by European colonists, although, there is a marked tendency towards the development of the native plantations in Assam as regards tea, and South India as regards coffee. It is to be hoped that sisal growing will, as far as is possible, be developed by the native cultivators, while ensuring them a fair share of the resulting profit.

The Mysore Durbar derives a large revenue from mineral resources and the sale of electric power used in the gold-mining regions. But, sooner or later, this source of revenue will vanish with the exhaustion of the gold mines, and it would be wise immediately to create new sources of revenue. Electric power would be available for new industries, such as that of sisal, that might be established in the country.

The Government and the public authorities of Mysore should pay attention to these suggestions and start sisal growing in the State on their own initiative, by such procedures as concessions of land for a seven-year period, facilities for payment, provision of plants, establishment of nurseries, etc. In conclusion, the author studies the question from the economic point of view.

422 – ***Bombax buonopozenze* var. *Vuilletii*, a Variety of Kapok New to Science.** — PELLEGRIN, in the *Bulletin du Muséum national d'Histoire naturelle*, No. 5, p. 379. Paris 1919.

The author announces a new variety of kapok from the Sudan, the fruit of an hour-glass shape, having been sent him in July, 1914, by M. VUILLET, Director of Agriculture of Upper Senegal-Niger. Of the two parts of the capsule, the lower one is spherical and the upper one tapering at the base which fits in the calycinal cupule; if the strangulation is too great, the terminal part of the fruit sometimes aborts, but it usually develops to the same extent as the lower part, and produces normal seeds. The author has given this variety the name of *Bombax buonopozense* P. Beauv. var. *Vuilleti*.

PLANTS YIELDING OILS, DYES, TANNINS, ETC.

423 – **Studies on the Oil Palm Kernels and Palm Oil in West Africa** (1). — I. HOUARD, Etude sur l'exploitation industrielle du palmier à huile, in the *Bulletin des Matières Grasses de l'Institut Colonial de Marseille*, 1919, No. 5, pp. 173-202. Paris, 1919. — I. BAILLAUD, E. and STIELTZES, A., Les amandes et l'huile de palme, preparation, commerce, industrie. — The Enquiry of the English Oil Seeds Committee, published by the *Institut Colonial de Marseille*, XXIV + pp. 346 + Figs. Marseilles, 1920.

I. — *A*) ON THE POSSIBLE OUTPUT OF PALM OIL AND KERNELS FROM DAHOMEY. — *Economic importance of the oil palm.* — The oil pal

(1) See *R.*, July-September, No. 888. (*Ed.*)

(*Elaeis guineensis*) is one of the chief sources of wealth in Dahomey; in fact, the customs statistics of the colony show that palm oil and kernels constitute about nine-tenths of the total exports, the value, in 1912, amounting to 19 759 739 francs out of a total of 21 318 505 frs., and, in 1918, 25 879 717 frs. out of a total of 28 723 143 frs.

No matter what future importance may be assumed by the exploitation of "karité" the cultivation of kola, cacao and cotton, the improvement in the utilisation of the oil palm will leave it supreme in the economic value of the colony.

Distribution of the oil palm. — The oil palm grows wild throughout Lower Dahomey, probably having escaped from the ancient forest, though, in many cases it has probably been planted by human agencies.

Dense stands occur in the zone between the shore and the seventh degree of north latitude. A fairly clear demarcation is found in the marshy part of the Lama, which separates the area of the really wild palms from that apparently planted by man. To the north of the seventh degree, the stands become more open and less extensive, save in certain regions in the circles of Abomey, Zagnanado and Hollidje. After 7.3°, there are only occasion clumps in damp spots and the palms are weakly, with elongated stipes and scanty foliage, while fructification is very scanty and irregular; in this area, it will be replaced by karité which is better adapted to the continental climate.

The presence of dense stands in Lower Dahomey corresponds fairly accurately with the geological distribution of the different soils. The most suitable soils are those derived from the river bars and damp alluvia, on account of their power to retain moisture.

The most important oil-palm zone, therefore, includes most of the land between the sea and a parallel line passing above Zagnanado.

Importance of the stands. — The dense stands are not far from the coast and they have the advantage of having the railways, rivers, lakes and lagoons at hand for communicating with the large buying centres or ports. These are the only stands of commercial and industrial interest, the small stands in the north being of no importance. These stands can be divided into two groups:

1) Lower Dahomey, an area 120 km. long and 60 km. wide, say 7 200 sq. km., from which 2 500 sq. km. of marshes, lakes, lagoons, savannah, brush, etc. should be deducted. This region represents an area of 4 700 sq. km. of stands of average or high density.

2) The dense stands in the circles of Abomey, Zagnanado, and Holli-Ketou, representing some 1 600 sq. km.

In round figures, the total area of the palm groves of industrial importance amounts to some 6 000 sq. km.

Density per hectare. — Excluding old and unproductive trees, it may be said that, if the average total density of Dahomey is 100 trees per hectare, the industrial density, including those *Elaeis* that produce normally, is not more than 50 trees per acre. This represents a safe minimum which is accepted so as to remain within the limits of an accurate evaluation.

Total industrial population of trees. — The total number of palms, whose crop could be gathered when the wild groves are generally organised, taking into account the above considerations and reckoning

on a practical density of 5 000 per sq. km., amounts to 6 000 × 6 000, or 30 million trees.

Average yield of an oil palm. — In a normal grove that is looked after to a certain extent, it can be said that each palm yields about 70 kg. of clusters a year. With the De-Yaya variety, which is practically the sole variety in the groves, the fruits constitute 53 % of the cluster, but, in certain fleshy forms yield as much as 66 %. Allowing for fruits that are malformed owing to compression in the centre of the cluster, there is an average proportion of 50 % of fruit in comparison with a total weight of fresh clusters. Therefore, an *Elaeis* gives an annual yield of 35 kg. of *utilisable* fruits.

Composition of the fruit. — According to SAVARIAU, the composition of the fresh fruit is as follows:

Variety	Pericarp	Shell	Kernel
Dé	42.5 %	45.0 %	12.5 %
Kissédé	49.1	52.6	18.3
Degbakoun	66.5	17.2	16.3
Votchi	79.5	7.9	12.6
Fadé	35.9	44.3	19.8

The palm-oil content of the pericarp, compared with the *fresh* fruit, is given below:

Variety	First analysis	2nd. analysis
De	24.9 %	21.2 %
Kissédé	29.1	26.5
Degbakoun	27.5	32.7
Votchi	47.1	43.7

Theoretical yield from 100 *kg of fruit.* — The theoretical yield from 100 kg. of the different varieties of *Elaeis* in Dahomey should be:

Variety	Kg. of oil	Kg. of kernels
Dé	21.2 to 24.9	12.5
Kissédé	26.5 to 29.5	18.3
Degbakoun	37.7 to 27.5	16.3
Votchi	43.7 to 47.1	12.0

Is should be remembered that the stand is practically entirely composed of the De Yaya variety. The Degbakoun, Kissédé, Votchi and Fadé varieties are very rare and scattered, while their total number is certainly less than one-tenth of the total *Elaeis* population.

However, the natives prefer to use the fruits of the Votchi and Degbakoun varieties for the preparation of the oil they use as food.

The industrial oil, then is, practically entirely furnished by the De-Yaya variety, which gives an average yield of 22 kg. of oil per quintal of fresh fruit.

The same does not hold good for the kernels of the different varieties, since only the pericarp of the Votchi and Degbakoun varieties is reserved for the production of edible oil, but it may be reckoned, taking into account the constitution of the palm groves, that each quintal of fresh fruit yields 22 kg. of kernels.

Products obtained using native methods. — The native method consists in pressing the fruit in the presence of water with the hands or feet. The average yield of oil from the fresh fruit is 10 %, whereas the theoretical oil-content of the pericarp of De-Yaya is 22 % of the fresh fruit (see above).

Theoretical yield of Dahomey in palm kernels. — As it has been calculated that there are 30 million palms that could be exploited in the future, and as each yields 35 kg. of utilisable fruit each year, and allowing for variations, parasitic attack, etc., an industrial yield of only 22 kg. per tree can be counted on, or an annual production of 600 million kg. of palm kernels.

As it has been assumed that 100 kg. of fresh fruit yields 22 kg. of oil and 13 kg. of kernels, the total theretical capacity of Dahomey would be 132 000 metric tons of oils and 78 000 m. tons of kernels. But as the kernels are less susceptible to factors that decrease the yield of pulp, the production of kernels may be said to be over 78 000 m. tons or, according to the author, 100 000 tons.

Possible theoretical exports. — The quantities of 132 000 m. tons of palm oil and 100 000 m. tons of kernels would not be available in their entirety for exports. Assuming that sufficient factories were established to extract all the fruit and that, in consequence, the oil is extracted with the minimum loss there would still be a wastage of some 3 %, representing the fat that would inevitable remain in the cakes, or some 18 000 tons. The local consumption for food, lighting and soap making absorbs about 15 000 tons a year. A deduction of 18 000 + 15 000 m. tons = 33 000 tons should therefore be made. As the kernels are not much utilised locally for the preparation of palm oil, the deduction to be made in this respect is insignificant.

Theoretically, therefore, the total quantity available for export would be 100 000 m. tons of oil and 100 000 tons of kernels.

Actual exportation. — On an average, the annual export is 12 000 m. tons of palm oil and 30 000 m. tons of palm kernels. The native consumption is about 15 000 m. tons of palm oil, so that the annual production is some 27 000 m. tons of palm oil.

The native by no means gathers the harvest from all the palms in a state of production, and he is usually content with exploiting the most

easily accessible groves and the most productive trees, as long as he makes his usual profit.

***

It will be seen that the utilisation of the stands of Dahomey is very small compared with the total theoretical capacity, the reason for this being: 1) the faulty harvesting of the groves; 2) the considerable losses of oil due to the exclusive use of the native method of extraction.

This state of affairs can be improved by cultivating the palm groves in a rational manner and, by founding extraction works, gradually approaching the theoretical capacity as soon as the agricultural population becomes sufficiently dense so as to be obliged to make use of all the available resources. This will take a long time and will call for slow progress. For the moment, there is no possible chance of the exports even overtaking or surpassing one half of the values ascertained previously.

The author discusses the methods of improving the cultivation of the palm and the organisation of the oil works.

***

Cultivation of the oil palm, its disadvantages. — There as two cases:

1) In the neighbourhood of Porto Novo, in the regions of Abomey and Zagnanado and in the immediate vicinity of most of the important centres, the palm groves are entirely cleared and the cultivation of food plants in the groves has led to the total disappearance of the high brush and is progressively destroying the low brush.

As the palms are freed, they benefit from the maximum of sunlight and the cultivation off the soil around the stools. They are visited each year, the dry leaves are cut of and the clusters are disengaged during their growth, so that the palms can give a maximum yield as they are little affected by the exhaustion of the soil due to crops that only grow in the top layer.

However, there is a serious defect in certain stands, as the groves contain many aged palms whose production keeps on decreasing until the tree dies. The young plants which usually spring up naturally, are often too few in number to keep the density constant, and, in addition, they often grow in such a way that gaps are produced when the old plants die

But, it may be said that palm growing in these regions is nearly perfect; all that is required is to maintain the stand and pay attention to manuring the soil in order to get the maximum yield from both food crops and palms.

2) In other cases, the oil palm is mixed with brush of varying thickness and height according to the speed with which the crops follow in the rotation. It then receives no special attention. At present, about half of all the palm groves receives either no cultural attention or is cultivated in a very rudimentary way.

Improvements in cultivation: increased stands. — The stands should be extended by increasing the density of open groups and by planting new groves on soil cleared for cultivation. More labour is necessary and factor-

ies should be provided that would liberate more labour. The cultivation itself should be improved and greater attention paid to it.

Rapid crop rotation. — The crop rotation is too slow, plots cultivated for 2 or 3 consecutive years on a forest clearing being abandoned to the brush for as much as 10 or 15 years. With a more rapid rotation, the native would plant his annual crops on the palm lands and would gradually exterminate the brush (as at Porto Novo and Abomey). One of the best methods is to encourage the spread of cacao and coffee growing in sufficiently open palm groves (1).

Selection and multiplication of the best varieties. — Nothing has yet been done in this connection. Certain forms of the De-Yaya variety should be studied and the Agricultural Department should install nurseries.

Harvest of the oil palm. — To do this, the native has to climb the palm on several occasions.

It is a long, difficult and often dangerous operation that may have to be repeated for plants with many fruits, if the clusters are gathered when just ripe. The older and, consequently, the taller the palm, the greater the labour of gathering the crop, although the production is smaller than that of trees of medium age and a shorter stipe.

The number of climbers has a tendency to decrease and it is probable that the extension of the groves will be hindered or even arrested by the lack of men to gather the harvest if the present method is continued.

Elaeis gives its maximum yield at 15 to 35 years, i. e., during a period when its stipe is relatively short and when the crop can be gathered with the aid of a ladder. After that age, the yield slowly decreases and becomes very small with very high trees. The constitution of the grove, then, should be radically changed. The young trees should be harvested with the aid of a ladder — an easy process. The climbers would only harvest those high palms that are still very productive. The very high and old palm trees should be destroyed as soon as the ascent becomes too difficult.

Groves organised in this way would contain two-thirds of *Elaeis* of the first category and one-third of the second, and the cultivator should try to keep this proportion constant.

This method, while rendering harvesting more easy, more rapid, and less troublesome — a man with a light ladder can visit many more trees than a climber in the same time — would above all result in regularising the crop and would allow the bunches to be gathered when fully ripe. The accomplishment of this is obviously far off, but it can really only be applied wholly, to new plantations, and progressively to certain natural groves when these have been entirely cleared of brush and judiciously completed.

B) Industrialisation of the crop.

The most urgent and successful remedy is to industrialise the crop, which would be shown by a rapid growth in the increase of the present production.

(1) This touches on the interesting question of intercalary crops in other types of plantation, particularly rubber (see *R.*, Feb. 1919, No. 205, VI) and the coconut palm (*R.* Febr. 1919, No. 201. II). (*Ed.*)

A first attempt at the installation of a factory has been made at Cotonou, in Dahomey. It failed, although use was made of a new process in which the whole fruit or pulp is pressed in the dry state, and which, with suitable presses and proper management, should give the best yield as it is much superior to the wet extraction process which requires more plant, longer and more frequent extractions and leads to increased loss.

The serious defect of the Cotonou factory was its distance from the producing centres, which made supplies uncertain and difficult to obtain on account of its remoteness and the difficulties of buying from a population that was not prepared. The experience obtained will be valuable in view of other attempts, although the " Fournier " type of press used was not satisfactory as regards the method of closing. All that is required is to benefit from the lesson of this first attempt, which did not survive its director, unfortunately, as he had shown that the process used was of interest and that its future was purely a question of machinery ; its adoption in most of the factories in the adjacent colonies is the best proof if its value and it will probably be used in all the works established in the future.

The type of factory required. — At present, it is not easy to advocate the adoption of any particular type of factory, using observations made on the actual plants, as they are for the most part, of an experimental nature. However, some idea may be obtained by comparing data furnished by different factories, provided that various factors not of an industrial nature, such as the density of the groves, the kind of ownership of the groves, abundance of labour, facilities of water supply, the commercial customs of the native population, be taken into account.

As the author paid an official visit to various factories on the Ivory Coast and in Togoland, he was able to collect a series of technical and commercial documents to serve as a basis for the determination of the type of factory to adopt. The oil works at Abidjan, Ana, and Imperia (Ivory Coast) and Batonou and Agu (Togo) are discussed.

Machinery. — As regards the machinery, the method and plant that should be adopted are given below :

1) Sterilisation and cooking of the fruit in double-bottomed, steamheated autoclaves, the true steriliser only being used when supplies are abundant.

2) Pressing the fruit in an hydraulic press, using a machine like that at Batonou which, for a factory treating 8 to 12 tons, had 4 presses and 3 boilers, the latter having an area 4 times that of the press cylinder.

3) Collection of the oil ; the first quality oil is purified by a heat treatment at 90-100° C., and by passing through a filter press.

4) Cooling in a tank and preparation for transport.

5) Depulping the pressed fruit (the " Fournier " depulper ; the " Trevor " depericarper, etc., are good but have serious defects ; there are also other types and suitable modifications will probably be made) ; the pulp is taken to the boilers and presses, and gives an oil of second quality and higher acidity, which is purified by heat, filtered, cooled and put in barrels without being mixed with the oil of prime quality.

6) The nuts pass from the depulper and can be sent at once to dry, either in the sun or in a hot-air drier, before passing to the crusher and the bath for separating the kernels.

Cost price, daily income and expenditure of a plant treating on an average 10 tons of fruits a day. — At pre-war prices, a plant like that described would cost, according to the author, 160 000 fr., or 16 000 fr. per ton (according to M. TREVOR, this price would be 200 000 fr., or 20 000 fr. per ton).

The price of the ton per day decreases rapidly with increasing size of the works and it is not more than about 8600 fr. for an oil factory treating 300 m. tons of fruit a day. In spite of this large difference, the large capacity plant is not economically possible at present in Dahomey, as it could not get sufficient supplies; it may be possible in the future, but now it is out of the question.

For a plant treating 10 tons a day, the working expenses for the whole year, calculated on a basis of 240 working days, amount to 485.20 fr. per working day, with depreciation calculated at 20 %. The daily receipts of such a factory, assuming that the fruit yields 18 and the kernels 13 % of oil, would be 675 fr. The daily profit, then, would be 190 fr., or 45 600 fr. in a year of 240 days.

The oils would not depend on local commerce, but the manufacturer would be his own exporter and thus add to his local profit the commercial profit obtained by selling his produce on the European market, which would realise a much higher profit than that shown above.

Conclusions. — The previous considerations all lead to the conclusion that the small-capacity oil factory can exist and make, in spite of risks that could not be foreseen in this study, a good profit for the owner. This is not so with large works, as the moment for them has not yet been reached.

The factory will not be able to work normally during the first year, as there will be the inevitable tentatives until everything works smoothly. It will suffer from irregular supplies of fruit, for the native, suspicious by nature, will hesitate before he decides to bring his products in as they are gathered; at least a year is necessary to educate him and every effort should be made to obtain the custom of the most powerful chiefs. But it is rare that an industry in its early stages does not have to overcome the difficulty of obtaining supplies of raw materials and the oil works established in a new country cannot escape this law.

The author regrets the lack of initiative shown by the big commercial installations in Dahomey, which confine themselves to trading. They ought to install oil factories as well as plantations, of coconuts, coffee, cacao, tapioca works, etc.

Now is the time for those who live mainly on the exportation of palm products to repair this error and increase their commercial capacity by establishing oil works which would double their profits. They have no need to fear competition from large companies that run greater risks for the sake of quick returns and which might establish themselves in the fertile soil of Dahomey, as there is room for everyone.

II. — The world war has led to the creation or considerable development of various industries, some of which will become permanent. Amongst these, the oil and fat industry in England, which was little developed before 1914, has greatly advanced.

When the importance of the question became evident, i. e., in the middle of 1915, the British Government appointed a committee composed of large African traders and important colonial officials to examine the

present situation and the future of the West African trade in edible and oil-producing nuts and seeds, and to report what measures should be taken to develop in Great Britain the industries that utilise these products.

The Report, which was presented to Parliament in June, 1916 (1) has been translated by the Colonial Institute at Marseilles and the translators (2) have examined the evidence and grouped the conclusions in a logical order, while eliminating any repetition. An introduction is given showing the chief conclusions reached in the report and the way the future of the production, trade and industry of the products of the oil palm should be considered.

In the second part of their work, the authors have collected all the information available regarding machines invented for depulping fruit, extracting palm oil and breaking the kernels. An appendix gives all the available information as to experiments carried on in the French colonies or in the former German colonies on the mechanical treatment of the fruit of the oil palm. In conclusion, statistics are appended showing the world's production and consumption of fats.

On account of the length of the work (400 pages) and the amount of detail it contains, it is only possible here to give an analytical summary of the contents.

Introduction (pp. IX-XXIV). — The pre-war palm-kernel industry in England and Germany.

II. — The present state of the fat industry in England and Germany.

III. — Measures for improving and developing the exploitation of the oil palm (This question is treated in detail in the first part of this abstract).

Part I (pp. 1-255). — *Critical Summary of the Report of the British Committee on Oil producing Seeds and Nuts.*

Chapter I. — Situation of the fat industry in England.

Chap. II. — Trade in palm kernels.

Chap. III. — Commercial advantages possessed by the Germans.

Chap. IV. — Maritime transport of palm kernels and oils.

Chap. V. — Advantages and disadvantages of different ports.

Chap. VI. — Establishment of a tax to assist the English palm-kernel industry.

Part II (many figures). — *Machinery for preparing palm kernels and oil.*

Hand machines for preparing palm oil : the Givira, Phillips and improved Philips machines.

Power machinery for preparing palm oil : — Hawkins machine (for removing the fruit from the bunch) — Forumier plant, Agupflanzung plant, Hawkins process (for pressing the whole fruit without breaking the nut) — Buchanan and Tyrell depulpers, the C. H. Dyer and G. Innes-Ward processes, Graig plant, Olier plant, Trevor depulper, process of the Maka plantation in the Cameroons (for removing the pulp from the nuts before pressing).

Shelling the palm nuts : — centrifugal shellers, other shellers, separation of the kernel and the broken shells.

Appendices. — I. Industrial and native methods for preparing palm oil on the Ivory Coast and in Gabon, by M. A. Boris (Agricultural Inspector of the General Government of French West Africa).

(1) *Report of the Committee on Edible and Oil-producing Nuts and Seeds.* June, 1916 [Cmd 82 47]. London, H. M. Stationery Office.

(2) *Bulletin des Matières Grasses*, No. 1, 1919. (*Ed.*)

II. The mechanical treatment of oil-palm fruits in Togoland and the Cameroons.

1) Extract from the Report of the Fats Commission of the German Committee for Colonial Economics.

2) Report of the German Dr. FICKENDEY.

3) Report of M. E. ANNET (Officer in the Army of Occupation in the Cameroon) on the Maka factory.

II. Palm-kernel cake, note by M. A. STIELTJES.

IV. World statistics for fats.

Movement of fats. — Imports of fats into France (special trade). — Exports of animal and vegetable fats from the French Colonies in 1913. — Exports of oil and oilseeds from British West Africa in 1913. — Average value of palm kernels. — Value of palm oil per ton. — Exports of palm kernels in 1913. — Exports of palm oil in 1913. — Exports of palm kernels and palm oils. — Exports and imports of groundnuts in 1913. — Exports, in 1913, of rape, copra, cotton, linseed, olive oil, castor oil, sesame.

The following figures relating to palm oil and palm kernels are taken from the large mass of world statistics : —

Countries	Exportation (in tons) of					
	Palm kernels			Palm oils		
	1896	1913	1917	1896	1913	1917
Gold Coast	13 242	9 754	4 768	9 568	3 500	816
Sierra Leone	21 400	49 201	58 020	1 305	2 500	2 280
Nigeria	85 553	174 718	185 998	49 995	83 090	74 619
Gambia	150	545	532	—	—	—
Guinea	2 659	5 170	7 070	200	164	265
Ivory Coast	1 247	6 950	—	4 812	6 014	—
Dahomey	25 151	26 370	17 015	5 524	7 971	11 865

424 – **Exploitation of the Oil Palm on the Ivory Coast and in Indo-China** (1). — *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 12, p. 381. Saigon, December-1919.

M. TEISSONNIER, Head of the Agricultural Service of the Ivory Coast, published, in the *Annales de l'Institut Colonial de Bordeaux* in March, 1919, a study on *Elaeis guineensis* and as this was of interest regarding the cultivation of this palm in Indo-China, M. VERNET has summarised the chief points of importance for the latter colony.

The oil palm is very sensitive to cultivation ; M. HALLET, obtained 2.3 kg. of fruits per tree (6 years old). Owing to this, a capital of 8 million francs has been devoted to the exploitation of this plant, which is a crop new to Sumatra.

(1) See *R.*, Feb. 1919, No. 200.

The exports from Guinea, the Ivory Coast and Dahomey have ranged from 20 640 t. in 1910 to 18 399 tons in 1917 for palm oil and from 44 785 44 785 t. in 1910 to 30 216 tons in 1917 for palm kernels (1).

In a natural grove, there are palms in all stages of development. Old *Elaeis* hardly produces at all, and when they are about 40 ft. high, the harvest is lengthy and difficult. If a climber can gather 15-20 bunches a day on light trees, he can easily gather 8 or 10 times more when the height does not exceed 40 feet.

The first aim in the management of old palm groves should be to eliminate the old trees and to replace them gradually by young trees just becoming or about to become productive.

The author is of the opinion that these considerations can be applied directly to the Indo-Chinese palm groves. It would be easy to arrange to replace the *Elaeis* regularly in the plantation as they become too old by establishing graded series under cultivation, which would in addition ensure the regularity of the production.

It would be useful to determine the economic limit of the productivity of *Elaeis* in Indo-China and the author points out that, at Suoi-giao, trees nearly 20 years old and on which the bunches are at a height of about 30 ft., have a decreasing yield, while it is difficult to gather their fruit. But the palms in question are in the middle of a *Hevea* plantation and, possibly, under other conditions they would have kept up their yield for a longer time.

The author suggests that a method that would give good results as regards this subject as well as selection, would be to start the first replacement stand between the lines at an age of 8 to 10 years, using plants obtained from parents giving the best yields.

In order to avoid cross-fertilisation, it would be possible, as indicated by M. TEISSONNIER, to prepare seed-bearers at the right moment and fertilise them artificially. It is recommended that the plants obtained from different producers should be planted separately so as to begin pure line selection as soon as possible.

425 – **Contribution to the Study of the "Guayacan" *Caesalpina melanocarpa*.** — Perez B., in the *Universidad de Tucumán, Informes del Departamento de Investigaciones industriales*, No. 6, pp. 17-24 + 2 Figs. Buenos Ayres, 1918.

Histological study of the stem and leaves ; tannin content of the fruit ; preparation of ink ; utilisation of the fruits for dyeing and tanning.

Out of 80.49 parts of the total residue left on evaporating the aqueous extract of the powdered fruit of *Caesalpinia melanocarpa*, 73.83 are soluble and 6.66 insoluble ; the soluble residue consists of 27.83 parts of tannin and 46 parts of non-tannin.

Ink can be made according to the following formula : — powdered guayacan fruits 12.5 gm. + distilled water 200 gm. + gum arabic 6.25 gm. + iron sulphate 6.25 gm + officinal solution of iron perchloride 5 gm.

(1) See No. 423 of this *Review*. (*Ed.*)

By using lactic acid as a mordant, the powdered guayacan fruits plus one-twelfth their weight of iron sulphate dye wool grey.

The powder of this fruit can apparently be used in tanning.

RUBBER GUM AND RESIN PLANTS

426 – **Effect of Removing the Pulp of Camphor Seeds on their Germination and on the Development of the Plant.** — Russell, G. A., in the *Journal of Agricultural Research*, Vol. XVII, No. 5, pp. 223-228 + 5 Figs. + 2 Pl. Washington, D. C.

A contribution from the Bureau of Plant Industry of the U. S. Department of Agriculture to the experimental study of the cause of the low germinating power of camphor seeds. The results of the germination tests, given in a series of tables and diagrams are discussed by the author.

It was found that by removing the pulp, of the seeds, they germinated 2 weeks earlier on an average, the percentage of germination being more than 5 times that of untreated seeds. The plants produced by seeds whose pulp had been removed give, when transplanted, taller, larger and more vigorous trees than seeds whose pulp had not been removed. The author states that in practice the removal of the pulp increased the germinating power some 200 times, which, together with the more vigorous growth of the seedling, largely compensates for the cost of the operation.

STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS

427 – **Analyses of Annam Teas** (1). — Bussy P., in the *Bulletin agricole de l'Institut Scientifique de Saïgon*, Year I, No. 10, pp. 308-309. Saigon, October, 1919.

The sample analysed came from a provision of 337 600 kg. supplied to the " Service de Ravitaillement " by M. Guenin, a trader at Tourane (Annam).

The method used for estimating the caffein (thein) is described in the Formulary of Dr. Bissemoret, p. 280 (published by Boulange-Dosse and Co., 4-6, rue Aubriot, Paris).

Substances estimated	Extra tea	Superior tea	Superfine tea	Fine tea	Recovery	Dust
Water	8.22 %	8.95 %	8.33 %	8.13 %	9.03 %	4.45 %
Acqueous extract . .	16.74	19.92	19.00	16.60	14.24	17.90
Ash	7.50	7.37	6.85	6.43	7.00	7.84
Caffein % of tea dried at 100° . .	3.09	3.75	3.45	3.55	2.72	3.56

428 – **On *Tagetes anisata* n. sp. a Source of Essential Oil.** — Zelada, F., in the *Universidad de Tucumán, Informes del Departamento de Investigaciones industriales*, No. 8, pp. 5 + 7 Figs. Buenos Ayres, 1918.

Botanical description and histological study of the Composite *Tagetes anisata* Lillo n. sp. (very close to, but distinguished by several cha-

(1) For Indo-Chinese tea, see *R.* Nov. 1918, No. 1243; *R.* Apr. 1919, No. 467 and *R.* March 1919, No. 601. (*Ed.*)

racters from *T. pseudomicrantha* Lillo and *T. micrantha* Cav.), very common in the Argentine in damp pastures in the zone between an altitude of 3250 and 9000 ft. By distilling the green plants in a current of steam, 0.7-0.8 % of a green oil was obtained, which was similar to, but not identical with that of common aniseed and which had the following characteristics :

Density at 15° C.	0.9862	Alcohol in C_{16} H_{18} O	0.852 %
Boiling point C.	214-218°	Ethers in C_{16} H_{17} $COCH_3$	1.082 %
Solidifying point	—6°	Acetyl index	23.4
Polarimetric deviation	—1°,10'	Total alcohols in C_{16} H_{18} O	4.311 %
Refractive index	1.5432	Free alcohols in C_{16} H_{18} O	3.229 %
Solubility in alcohol at 90°	1 : 5	Iodine index	158.5
Saponification index	3.1		

429 – **Tobacco Growing in Algeria.** — MANCHERON, P. in the *Revue Agricole de l'Afrique du Nord*, Year XVIII, No. 30, pp. 136-140 + 3 figs. Algiers, February, 27, 1920.

Tobacco is of considerable importance among the crops of the French colonies in North Africa. It is the crop that has so far benefited most from rich soils of all the valleys near to the coast that have not yet been planted with vines. It may thus be justly considered as the chief industrial plant of the country. Before the war, Algeria produced 60 000 quintals of dried tobacco leaves, valued at about 4 million francs.

Tobacco growing is very expensive, but it yields greater profits than cereals and so its cultivation is continued. But, in certain places, there seems to be a change of opinion and the possibility is being contemplated of replacing tobacco by the sugar-beet (1).

Tobacco soils suit the sugar-beet perfectly, as both plants have the same requirements. But while tobacco removes all the food material it has extracted from the soil, the sugar-beet restores the greater part of the inorganic salts it contains, which is very important, considering the cost of fertilisers.

The author thinks that tobacco growing should not be completely abandoned in Algeria but, when there are sugar factories in the country, it will pay to reduce tobacco growing as far as possible, confining it to compact clay soils with damp subsoils, such as those in the Seybouse valley, near Bone.

VINE GROWING

430 – **Production of Vines Grafted on American Plants in North Africa.** — VINET, E., in the *Revue agricole de l'Afrique du Nord*, Year XVIII, No. 24, pp. 35-38. Algiers, January 9, 1920.

The author (Professor of Viticulture at the Agricultural School at Maison-Carrée, Algiers) gives advice on the choice of stock suitable for vine growers in North Africa who have to replace their ungrafted vines by vines grafted on American plants.

The following are best suited for the type of soil described : —

1) Alluvial soils, rich, open, fertile, with little lime, retaining moisture in summer : — Riparia Gloire de Montpellier, 3309, 3306.

(1) See *R.*, Feb. 1920, No. 208. (*Ed.*)

2) Alluvial soils, rich, with medium lime (up to 50 %), compact and dry but not excessively so : — 420 A, 161-49.

3) Compact, very dry soils : — 93,5, 18 808 and 18 815.

4) Compact, damp soils : — 93-5, 216[3] (under trial).

5) Soils containing over 50 % of calcium carbonate : — 41 B and Berlandieri.

431 – **The Role of the Callus in Grafted Plants.** — See No. 403 of this *Review*.

FORESTRY

432 – **Forestry in Libia.** — I. Fossa P., Primo esperimento dell'A.mministrazione italiana in Tripolitania per consolidare e rimboschire dune e terreni interdunidici, *Ministero delle Colonie, Ufficio Economico, Bollettino di Informazioni*, Year IV, Nos. 7, 8, and 9, pp. 287-302 + 1 Fig. + 1 Map. Rome, 1916. — II. Secondo rapporto del R. Ufficio Agrario di Tripoli sugli esperimenti di consolidamento e rimboschimento di dune mobili, *Ibid.*, Nos. 10, 11 and 12, pp. 497-521 + 19 Figs. 1917. — III. Terzo rapporto sugli esperimenti di consolidamento e rimboschimento di duno mobili (Relazione del R. Ufficio Agrario di Tripoli), *Ibid.*, Year VI, N. 1, pp. 36-45 + 4 Figs. 1919. — IV. Quarto rapporto sui risultati degli esperimenti di consolidamento delle dune mobili in Tripolitania, (Campagna 1917-18), *Ibid.*, pp. 47-56 + 2 Figs. — V. Leone, J., Il valore agricolo della Tripolitania, *Ibid.*, pp. 20-25 + 9 Figs. — VI. Mangini, A., Appunti sulla vegetazione della Cirenaica e sulla utilizzazione agraria, in l'*Agricoltura Coloniale*, Year XIII, p. 515-546 + 7 Figs. + 1 Map. Florence, 1919.

I, II, III, IV. — The Italian administration of Tripolitania undertook, in February, 1916, afforestation experiments on soils invaded by dunes. The first researches showed that the soil of the dunes and steppes is practically the same as that of the oasis of Tripoli, the only difference being the difficulty met with in watering ; in addition, the rainy season there is limited to the period between October and February, with 300 to 400 mm. of water.

In order to grow forest trees successfully in this region, it is necessary :

1) To choose xerophilous or at least drought resistant plants, which should be obtained from a local nursery.

2) To use long and robust plants or cuttings, so that, when planting them, they can be pushed down to the lower layers where there is some moisture, even in summer.

3) To plant and sow either a few days before or during the rains.

4) Before growing them on a large scale, carry out tests in different months and with different methods.

The experiments were continued up till autumn, 1918, and lessons and rules can already be deduced from them, so that it is possible to establish a programme for the improvement of land invaded by sand.

The technical method for consolidating moving dunes, as far as it can be determined from experiments lasting 3 years, is suitable for continental or interior dunes only as these differ essentially from the maritime dunes in the fact that their movement in any fixed direction is much slower or does not occur ; again, new deposits of sand are either not formed or formed very slowly. As the conditions are more simple, the problem is consequently more easy to solve. In fact, in experiments carried out near Tripoli, it was not found necessary to provide works for pro-

tection against the dunes or even to fix the sandy surface with the help of herbaceous plants, before proceeding to afforestation, which can be begun the first year.

As regards the experiments for fixing and afforesting the moving dunes on the coast, the projects for the territories of Zuara and Lebda (*Leptis Magna*) near Homs are now under consideration. The work can only be started in 1919-1920 and the procedure will be based on the classic methods employed in Europe, particularly in Gascony. The practical application of these methods will show the modifications necessary in the case of the coastal dunes of Libia and after this the full plan for work on the coastal zone troubled with sand will be drawn up.

Receding steppe and hollows between dunes. — In many cases, it is sufficient to forbid any thoroughfare, pasturage and cropping so as to allow the natural vegetation to spring up and increase, and thus consolidate the soil. Afterwards, pasturage in moderation may be allowed. If it is desired to profit from these soils after their fixation by the natural vegetation, trees such as the *Tamarix*, *Parkinsonia*, mulberry and Aleppo pine should be planted.

True dunes. — Although low, isolated dunes can be planted all over their surface in one operation, with large dunes or those that form part of a large sandy area, the process must be gradual. After ascertaining the superficial area that requires consolidating, barriers should be put up to prevent men and animals passing across, but the barriers must not offer any obstacle to the passage of sand or wind. If, however, the surface in question is in contact on one of its sides with other dunes that are not yet consolidated, it will often be necessary to erect hedges or fences, so as to avoid fresh deposits of sand for a certain time ; then plantation can be begun passing from the periphery to the centre and from bottom to top. In the case of dunes with very steep slopes, it is sufficient to plant from the base to about half-way up, then up to the top ; if not, the work of consolidation should be divided into three periods.

While planting (using plants or cuttings, according to the species), hedges or defence rings should be formed with herbaceous or bushy steppe plants (especially with *Malcomia aegyptiaca*), so as to divide the planted area like a chess board, the size of whose squares should be greater or smaller as the surface is more or less sloping. These hedges are made by placing the plants in a small furrow in the sand in such a way that one-third is left uncovered, and pressing down the surrounding sand very formly.

The distance between the plants is very variable and is fixed, by the growth of the particular species and the slope of the surface. In any case, it is better to plant at greater distances than is usual in ordinary agricultural plantations, so that the roots can have full play in the largest mass of soil compatible with their consolidatory function. The depth of planting should always be from 75 to 100 cm.

During its growth the plantation should be watched and carefully examined, especially after the advent of strong winds, so as to repair any eventual damage caused by the movement of the sand ; where the roots

of the plants are uncovered they will be covered up again, and where the plants are buried they will be uncovered. In the second year the damaged portions of the hedges will be repaired and any cuttings that have not taken root will be replaced ; at the same time, new sections will be planted until the whole area is covered.

Certain of the species planted should be pruned in the second year (*Tamarix, Parkinsonia*, etc.), others, such as robinia or reeds, etc., being pruned later on, and each tree should be pruned according to its own particular method. The best type of pruning for the species mentioned is nearly always cluster pruning, except in the case of trees to which it is unsuited.

Plants certain to be successful : — *Tamarix articulata, Robinia Pseudo-acacia, Arundo Donax, Parkinsonia aculeata, Pinus halepensis.*

Plants whose success is still uncertain or depending on a cultural technique not yet fully proved : — *Populus italica, Acacia longifolia* and spp., *Eucalyptus* sp., *Casuarina* sp., *Ricinus communis, Retama Raetam-Tamarix gallica, Grenvillea robusta, Cryptostegia* sp., *Brachychiton diversifolium, Sophora japonica, Morus nigra, Melia Azederach, Cercis Siliqua, strum, Pistacia vera, Pinus canariensis, Pinus Pinea, Phytolacca decandra Mesembryanthemum acinaciforme.*

Known to be scarcely suitable : *Opuntia Ficus-indica, Olea* sp., *Ailanthus glandulosa, Agave* sp., *Nerium Oleander, Punica Granatum, Populus alba, Eucalyptus Globulus*, etc.

V. — Amongst the plants tested on a large scale and with a considerable number of species, without excluding those already existing in Tripolitania, but which, up to the present, have been cultivated in irrigated soil, the following trees have been found to be particularly suitable for the purpose in question : — *Eucalyptus* spp., *Acacia latifolia* and *A. longifolia, Tamarix*, pines, *Casuarina* spp., *Parkinsonia aculeata*, the cypresses, and other species about which a definite opinion cannot yet be given. The following trees are specially important : — *Eucalyptus* (*rostrata, resinifera, saligna*) and *Tamarix articulata*, which are specially adapted for these conditions of growth. In two years, wind-breaks planted with these trees have formed real walls protecting the irrigated orchard of the Agricultural Institute at Sidi-Mesri ; growing on the open steppe, they are much admired by visitors.

The success of both dry and irrigated orchards depends on an essential condition too often neglected by the natives and the Italian colonists, namely, wind defences. Owing to their regularity and velocity, the winds are more to be feared than the usual drought, for they often strip the young plants of their leaves in winter, destroy, the tender buds and shoots, and, when they are laden with sand, tear off the bark from the young plants at some distance from the soil. Therefore, the chief factor in obtaining a successful orchard is to be armed against the destructive action of the wind.

This is why, after choosing the site for the orchard, the first trees to be planted are those that will serve as a wind-break later on ; these trees,

while still young can be protected by little walls of beaten earth, so that they can properly develop their root-system and provide, 2 or 3 years, later, a splendid wind-break for the young fruit trees planted in the meantime. Such wind-breaks should not only surround the orchard but divide it into sections of a size corresponding with the species of fruit tree grown.

Besides *Eucalyptus* spp. and *Tamarix articulata* the *Casuarina* spp. and cypresses can be used as wind-breaks, but they are most suited to irrigated orchards where they can benefit from the irrigation.

VI. — In Cyrenaica, the conditions from the standpoint of forestry and ecology, can be summarised as follows : — All the vegetation of the Bengasi plain is of the xerophilous type ; in the north, the soil is thickly covered with high underwood and a few trees, with good pastures and a few prairies ; the flora is of the Mediterranean type. As one goes south, the underwood diminishes and finally disappears and is replaced by the steppe of varied nature ; the species belonging to the desert flora become more numerous, the pastures become smaller and poorer, and the vegetative cycle of the annual florets is shortened. The botanical appearance, so different between the northern and southern regions of the plain of Bengasi, is not only due to the quantity and distribution of the rainfall, but is influenced considerably by the southern winds ; their depressing action on plants, which is very intense in the pre-desert area, becomes less serious as they approach the north.

The vegetation of the northern slope of the plateau of Cyrenaica, however, belongs to the *Lauretum* forest zone, according to the classification of Mayr. All the species characteristic of the *Lauretum* zone, or a greater part at any rate, are represented in the flora of that region of Cyrenaica that faces the Mediterranean. A considerable part is covered, as regards the commonest types, with low and high coppices, thickets and woods, isolated trees, and, towards the south side, a large part of the first and second terraces appears to be more or less thickly, though irregularly, wooded. Above this region, through a territory of varied, occasionally irregular configuration, one arrives at the dividing line of the watershed, followed by the gradual descent of the southern slope. The area lying between the southern limit of the region of thickets and woods and the dividing line of the watershed, which is very irregular, now narrower, now wider and extending towards both north and south, is generally bare of trees or shrubs. It becomes more important to the east of the plateau of Cyrenaica and to the west of that behind Merg. Towards the west, the landscape, the appearance of which is poorer and poorer, runs into the plain of Bengasi at the point where the thickets end and where the immensity of the steppe spreads away far out of sight. Towards the east, the bush vegetation, already impoverished around Derna, retains some slight importance in the direction of Marmarica.

The same associations, i. e., thickets, but more often woods, appear on the southern slope, where they cover immense areas, especially along the " ouidian ", while, further to the south, the steppe dominates.

433 - **Red Gums (*Eucalyptus* sp.) and the Utilisation of their Wood in Cabinet-Making.** — TRABUT, in the *Comptes rendus ds Séances des l'Academis d'Agriculture de France*, Vol. VI, No. 1, pp. 37-39. Paris, January 7, 1920.

Since the eucalyptus was introduced into Europe and North Africa, the merits of this Australian wood have been as much contested as praised, the reason for the difference of opinion being an absolute lack of method in the tests. Practically all the species introduced (about 100) have been confused with *E. globulus*, which is the best known one, and more absurd prejudices have been entertained than sound appreciations of the facts. It is now time to investigate the many uses of the wood of these trees, which grow admirably in the Mediterranean region and which grow 5 times more quickly than the other indigenous or acclimatised trees.

The author has studied the acclimatised species of eucalyptus since 1875 and he is certain of their great value. In the present article, he draws attention to the red gums — those with red or pink wood.

These trees, now fairly common in the Mediterranean region, can be used for making fine furniture with the precise appearance and value of mahogany. Furniture makers are afraid to use this wood, as the public considers eucalyptus wood to be worthless. There is no reason for this prejudice.

The species of *Eucalyptus* which can furnish red or pink wood like mahogany, and already commonly grown, are : — *E. rostrata* and a hybrid ; *E. algeriensis*, which is the cross *E. rostrata* × *E. rudis ; E. botryoides*, the pseudo-mahogany of the Australians, and a hybrid *E. botryoides* × *E. rostrata* = *E. Trabuti* Vilm ; *E. terreticornis* and its hybrids ; *E. rudis ; E. punctata ; E. diversicolor.*

All these species are easily grown in North Africa ; *E. algeriensis* has even become naturalised and is often found growing on the banks of watercourses in a semi-wild state.

On account of the present exhorbitant cost of furniture, it would be well worth while to give a better place to such a valuable wood which can be produced easily and cheaply.

LIVESTOCK AND BREEDING.

434 - **Stock Poisoning due to Oak Leaves.** — MARSH, C. D., CLAWSON, A. B. and MARSH, H., in the *U. S. Department of Agriculture, Bulletin* 767, pp. 36.. Washington, April 18, 1919. HYGIENE

Although there is an abundant literature on poisoning caused by acorns, very little is recorded on poisoning due to oak leaves, and for this reason the authors took up the subject. The experiments were carried out on cattle, using the leaves of the scrub oak (*Quercus Gambellii*) and the following facts were observed :

Continuous feeding with oak leaves may produce a disease which sometimes ends fatally. In a herd feeding on the same pasture, only a few animals are affected. The most obvious symptoms are : — constipation, mucus and blood in the excreta, emaciation and oedema.

A diet composed solely of oak leaves is not sufficiently nourishing to allow of a normal increase of live weight. But, if other foods are added, they may constitute a maintenance ration ; 1.5 kg of alfalfa hay per head per day will suffice.

Oak leaves may be injurious in any season, but the cases of poisoning are mostly observed in spring, because there is a scarcity of other forage at that time and the animals find the young oak leaves appetising. Later on in the season, the animals continue to eat varying quantities of oak leaves, while still eating the other forage available, which causes still further trouble.

435 - **Stubbornness: a Note on Equine Pathology.** — Bianchi, G., in *Il Coltivatore*, Year 66, No. 6, pp. 158-160. Casale Monferrato, February 29, 1920.

The classic definition of stubbornness is the sudden stoppage of the animal without apparent cause in the middle of the a road, while neither kindness nor punishment can make it budge. Stubbornness, however, may assume many other forms, such as a refusal to start when harnessed, or to start again after a stoppage, etc. It is a redhibitory vice in contracts for the sale of horses and is usually ascribed to bad temper.

Professor Bassi has collected an enormous number of cases of madness and intractability in the horse due to cranial asymmetry. The author thinks that stubbornness and the phobias of the horse in general are, similarly, due to a pathological state of the vaso-motor system. In certain horses, either work, their first movements or some other cause, makes the circulation more brisk, and sight becomes dim and finally disappears; the horse stops, trembles, and is afraid to more forward until, when the circulation becomes normal, it loses its fear and starts work again. This explanation is confirmed by the fact observed by the author that 80 % of the horses afflicted with stubbornness have deficient sight; when the ophthalmia is cured, the stubbornness disappears.

436 - **Seroprophylaxia and Serotherapy for Tetanus in the Mule.** — Perucci, P., in the *Nuovo Ercolano*, Year XXIV, No. 12, pp. 145-148 ; No. 13-14, pp. 162-172 ; No. 15, pp. 176-180 Turin, June-August, 1919.

In Southern Italy, mules are not castrated as a rule. When, during the war, the Remount Commission found it necessary to buy large numbers of mules for war services the owners were obliged to have them castrated, which was done on a large scale, often by unskilled persons and without any antiseptic precautions. After some time tetanus naturally appeared, at first sporadically, then more frequently. The following neasures were employed to cope with this state of affairs :— 1) the sellers of mules were obliged to have them castrated by a veterinary surgeon ; 2) the use of anti-tetanus serum was made obligatory, as a preventive measure, for mules about to be castrated ; 3) immediate recourse to serotherapy was insisted upon in the case of animals affected by tetanus. These measures were quite successful and the cases of tetanus soon disappeared.

The author has studied the disease on the spot, he has contributed to the struggle to overcome it and he concludes from his observations and

xperiments that: — 1) the preventive dose of anti-tetanus serum found uitable for the horse will also preserve the mule from infection by teta- us; this dose, using the Italian Military Veterinary Laboratory serum, from 5 to 10 cc., according to the strength of the serum; 2) the serothe- apy of tetanus often cures the mule, if applied at the onset of the disease large doses of serum given in various ways (sub-cutaneous, endovenous);) with both the mule and horse, if a preventive dose of serum *given late* oes not suffice to protect it against tetanus, it will considerably change ie course of the disease, which will be easier to cure.

37 – **Spirochaetosis of Cattle in Brazil, and its Transmission by the Tick *Margaropus australis*.** — Brumpt, A., in the *Bulletin de la Société de Pathologie Exotique*, Vol. XII, No. 10, pp. 748-757 + 1 Fig. Paris, December 10, 1919.

The author happened to discover bovine spirochaetosis during reseach one in France on the biology and pathogenic role of cattle ticks obtained om Brazil. This tick *Margaropus australis*), found in the Brazilian aughterhouses on normal cattle, produced thousands of embryos which ifected a calf with a mixed piroplasmosis consisting of *Piroplasma bi- eminum* and *P. argentinum*.

Starting from the first ticks, the author obtained nine successive ge- erations on cattle. Certain lots of ticks lost their infection with *P. bi- eminum* at the third generation and their infection with *P. argentinum* the sixth. At the eighth generation, a cow was affected slightly with *pirochaeta Theileri*.

The pure spirochaetosis observed was extremely benign and adds to ie number of obscure diseases studied by C. Nicolle and C. Lebailly.

Immunity, or rather tolerance, is quickly acquired; the thousands infectious embryos placed on the cow mentioned above had produced reaction whatever 75 days after infection.

The author points out that only the name of *Spirochaeta Theileri* averan (1903), parasitic on various mammals (cow, horse, sheep. buffalo. oat), should be retained, and the names *Spirochaeta equi* and *S. ovina* ould become synonyms.

38 – **Vaccination of Cattle against Anaplasmosis.** — Lignières, J., in the *Bulletin de la Société de Pathologie Exotique*, Vol. XXII, No. 10, pp. 765-774. Paris, December 10, 1919.

By choosing the least virulent *Anaplasma argentinum*, or those from ttle that have long recovered, and passing them successively and at ng intervals through the sheep and goat (1), such a fixity is attained in ie attenuation of the parasite that they can be used almost without danger ven for immunising cattle against natural anaplasmosis.

The author now uses this new method on all the breeding cattle in ie Argentine that are to be sent into regions where anaplasmosis exists.

(1) See *R.*, Febr., 1920, No. 220: "On Anaplasmosis: on Cattle Sheep and Goats are sceptible", by the same author. (*Ed.*)

439 – **Avian Typhosis and the Bacterophagus Microbe.** — D'HERELLE, F., in: I. *Comptes rendus de l'Académie des Sciences*, Vol. 169, No. 18 (Nov. 3, 1919), pp. 817-819; II. *Ibid.*, No. 20 (Nov. 17, 1919) pp. 932-934; III. *Ibid.*, Vol. 170, No. 1 (Jan. 5, 1920), pp, 72-75. Paris; IV. *Comptes rendus des Séances de la Société de Biologie*, Vol. LXXXII No. 30, pp. 1237-1239. Paris, Nov. 29, 1919; V. *Ibid.*, Vol. LXXXIII, No. 3, pp. 52-53. Paris, January 24, 1920 (2).

I. — ON AN EPIZOOTY OF AVIAN TYPHOSIS. — Once, installed in a region, avian typhosis becomes enzootic. It particularly affects adult fowls, which are more sensitive to it than pullets or aged animals. In France, it has decimated the poultry yards every year since 1916. It is impossible to foresee the duration of the enzooty for, besides the scarcity of information on the epidemiology of the disease, it has always assumed a more localised character in the United States, where it has long been known; therefore the conditions are very diverse.

If it is difficult to imagine measures for preventing the propagation of the disease by men, who carry the particles of virulent matter on the soles of their boots, or by animals who carry them on their feet, it is not the same with another method of dissemination described by the author This is as follows: certain poultry keepers in regions where the disease is rife, sell their stock as soon as the disease appears; the fowls are sent to the town markets and, though the majority are sold as food, it sometimes happens that fowls are bought for breeding, especially in the departments devastated by the war, and thus new centres of infection are set up.

II. — ON THE ROLE OF THE BACTEROPHAGUS MICROBE IN AVIAN TYPHOSIS. — The epizooty of avian typhosis mentioned previously enabled the author to make fresh observations on the role of the bacterophagus microbe in the genesis of diseases of intestinal origin.

In the intestinal content of any fowl, healthy or diseased, living in a normal or in an infected environment, a filter-passing bacterophagus microbe is always to be found. In addition, the presence of this normal intestinal guest is common to all the vertebrates, but its activity and virulence essentially varies in quality and quantity.

This bacterophagus microbe can be considered as the agent of a contagious disease attacking the bacteria; the bacterophagus microbe is to the pathogenic bacterium what the pathogenic bacterium is to the higher organism which it infects; the modalities of the action are comparable. The virulence of the bacterophagus microbe for *Bacterium sanguinarum* (the agent of avian typhosis) can only be observed in an infected medium; the absence of virulence is the absolute rule with healthy fowls and, on the other hand, with fowls that will succumb or have succumbed.

In a poultry yard where typhosis occurs, the disease occurs solely in fowls that contain in their intestine a bacterophagus microbe that is

(2) For other work by D'HERELLE on the filter-passing bacterophagus microbe that plasmolyses the bacillo of dysentery, see: *Comptes rendus de l'Académie des Sciences*, Vol. CLXV, p. 373, 1917; vlo. CLXVII, p. 970, 1918; Vol. CLXVIII, p. 631, 1919; Vol. CLXIX, p. 932. 1919; *Comptes rendus des Séances de la Société de Biologie*, Vol LXXXIII, No. 4, p. 97, Jan. 31, 1920. (*Ed.*)

nactive as regards *B. sanguinarum*. The animal is immune from the moment when the intestinal microbe acquires a bacterophagus power over the pathogenic bacillus and the immunity persists as long as this power remains sufficiently high to ensure the rapid destruction of the bacilli ingested ; the ingestion of pathogenic bacteria with sufficient frequence constitutes the chief factor in the maintenance of the activity of the bacterophagus microbe as regards the bacillus under consideration ; the state of the contents of the intestine constitutes another factor. In the rare cases when recovery takes place this is invariably preceded by an increase in the virulence of the bacterophagus intestinal microbe for the pathogenic bacillus. The author found that the bacterophagus microbe of a fowl that recovered, spread in less than 3 days to all the fowls in the yard, which explains the sudden and apparently inexplicable arrest of the disease. The arrest always corresponds to the moment when a fowl recovers that had been seriously affected.

All the facts quoted above have been reproduced experimentally.

The history of the disease ultimately records the history of the struggle between the two agents ; the immunity is transmissible between individuals of the same species ; the immunity is as contagious as the disease itself.

The ingestion of a culture of the bacterophagus microbe that comes from a highly virulent stock brings about the sudden cessation of the enzooty on the same day as its administration.

III. — The defensive action against intestinal bacteria and the etiology of intestinal diseases. — The author extended his researches to man, the monkey, cat, cow, pig, rabbit, rat, and duck, and found in all the species, on the one hand the very frequent presence of dysenteric, typhoid and paratyphoid germs and, on the other, the constant presence of the bacterophagus microbe which, in the presence of an invading organism, becomes rapidly accustomed to it and destroys it, whence the frequent abortion of diseases. In resistant inviduals, it becomes immediately accustomed, while, in sensitive individuals, the adaption may as an exception, not take place, in which case, the disease declares itself.

One of the chief causes of the delay in the adaption of the bacterophagus microbe to bacterophagy is probably some physical or chemical change in the condition of the contents of the intestine in which the phenomenon takes place.

IV. — On the bacteriophagus microbe. — So far, the author has isolated from various sources, strains of bacterophagus microbes that are active against the following bacteria :— The dysenteric bacilli of Shiga, Flexner and Hiss, *B. typhosus, paratyphosus* A and B, *B. enteritidis*, hog cholera bacillus, *B. Coli, B. Proteus, B. sanguinarum* Moore, and *B. bullarum*.

V. — On the cultivation of the bacterophagus microbe. — The virulence of this microbe varies greatly from one stock to another, but its action is always the same : all the living bacteria are attacked and when

the action is over, reinfections on any medium remain sterile. The best method for obtaining the bacterophagus microbe is as follows : —

To a MARTIN tube of peptonised broth, alkalinised to - 5 with phenophthalein, is added a concentrated emulsion of the bacillus on which it is desired to make the bacterophagus microbe act, an emulsion from a agar culture not more than 24 hours old ; this is then infected with a known quantity of a filtrate of the excreta to be examined for the bacterophagus microbe, and incubated at 37° C. If this microbe is present, the living bacteria are plasmolysed, which is shown macroscopically by the clearing of the medium. With a slight infection, the medium is limpid in 7 to 8 hours ; with a heavy infection, the action is much more rapid (1).

ANATOMY AND PHYSIOLOGY

440 – **The Mineral Metabolism of the Milch Cow.** — I. FORBES, E. B., BEEGLE, F. M., FRITZ, C. M., MORGAN, L. E. and RHOE, S., in the *Ohio Agricultural Experiment Station, Bulletin* 308, pp. 451-488. Wooster, Ohio, January, 1917. — II. FORBES, E. B., HALVERSON, J. O. and MORGAN, L. E., with the collaboration of SCHULZ, J. A., MANGELS, C. E., RHUE, S. N. and BURKE, G. W., *Ibid., Bulletin* 330, pp. 91-134, Sept., 1918.

The aim of the experiments described in this study, the second dealing with the same question (2), was to find whether mineral equilibrium can be maintained on rations containing the maximum quantities of mineral nutriment obtainable in common practical feeds ; to ascertain the effect of adding to these rations large amounts of calcium, magnesium and phosphorus in the form of supplements, such as inorganic salts ; and to explain the limited use made of mineral nutrients when consuming food ordinarily in liberal quantities.

The experiments were carried out with 6 Holstein cows in collection periods of 20 days, separated by intervals of 10 days. All the cows were in their 2rd, 3rd, or 4th lactation period. The milk produced varied from 38.7 to 58.35 lb. per head per day.

So as to provide a maximum of calcium, magnesium and phosphorus, a basal ration was used of clover or alfalfa hay (leguminous roughage) + maize silage + cotton cake + linseed cake + wheat bran. Maize flour (shown in the table as maize) was used as a source of carbohydrates. During the first experimental period, the variable constituent of the ration was the roughage and 3 cows were given clover hay and 3 were given alfalfa hay. During

(1) Mr. Tamezo HABESHIMA has found, in experiments on animals, that the bacteriolysate produced by the filter-passing bacterophagus microbe, when put in contact with the pathogenic bacillus, gives good results in preventive vaccination ; in addition, animals experimentally rendered germ carriers can be sterilised, as this principle is found in the gall-bladder after an intravenous injection. He maintains that the filter-passing bacterophagus microbe is not living matter but a sort of catalyst that can be extracted from the lysate by acetone or ether. The powder on the waxy deposit thus obtained has a much greater bactericidal power than the lysate itself. — *Comptes rendus des Séances de la Société de Biologie*, Vol. LXXXIII, No. 8, pp. 219-221. Paris, February 28, 1920. (*Ed.*)

(2) The first study is summarised in *R.*, July, 1917, No. 648. A general summary of the results of this work and of the two papers abstracted above was made by FORBES, in the *Journal of Dairy Science*, Vol. II, No. 1, pp. 9-18. Baltimore-London, January, 1919. (*Ed.*)

the second period, the variable constituent was the salt, of which 3 cows were given twice as much as 3 others ; another variation consisted in giving calcium carbonate to 2 cows and precipitated bone flour to 3 others. A series of 17 tables contains : — the average food consumption per day ; the quantity of milk produced and the live weight of the cows ; the percentage composition of both food and milk ; the weight, in grams, of each constituent of the foods consumed and of the milk produced in one day ; the weight of the constituents of the urine and faeces ; the quantity of mineral constituents and nitrogen ingested daily and their metabolism ; the quantity of mineral elements in the daily ration expressed in cc. of normal solution ; the utilisation and elimination of the nitrogen ; the coefficient of digestibility of the rations ; the distribution of the unretained elements between the milk, urine and faeces. Some of the more important data are given in table I. See page 478.

The results are summarised below : —

The prevailing idea, that all animals whose ration consists in great part of leafy forage consume and digest the mineral elements in abundance, is not correct in relation to cows during the ordinary liberal milk production. With rations consisting of the ordinary farm foods, specially chosen to supply the maximum supplies of mineral nutrients, all the calcium, magnesium and phosphorus metabolisms remained negative, as in the previous year. On greatly increasing the calcium, magnesium and phosphorus content of the rations by increasing the quantity of food consumed and by adding large quantities of calcium carbonate and precipitated phosphate, all the calcium metabolisms and all the magnesium metabolisms save one were negative, but the phosphorus metabolisms became positive. This offers satisfying proof that, in improving milch cows by selection, we encounter limited capacities for digesting calcium, magnesium and phosphorus, and the incapacity for accumulating reserves of these elements before these limitations appear in their ability to digest and make use of the inorganic element. The authors suggest that a limited capacity for the formation of hydrochloric acid might be one of the limiting factors in the utilisation of the calcium, magnesium and phosphorus in the ordinary food and of the mineral supplements.

Doubling the usual dose of sodium chloride does not increase the retention of calcium, magnesium and phosphorus ; 1 oz., of salt per day per head provides sufficient sodium for cows yielding 45 lb. of milk per day, and a ration of 1-2 oz., of salt per head per day, according to the quantity of milk produced, suffices for the sodium requirements. Rations that contain sufficient sodium for the needs of the cow usually supply a proportionately great quantity of chlorine.

All the rations studied seemed to furnish sufficient potassium, and normal rations, therefore, probably contain enough for the cow.

The different circumstances that determine the way in which the food substances absorbed are eliminated have usually no corresponding effect on the retention of these elements in the organism. In some cases all the sodium excreted was in the urine ; in others, it was nearly all in the faeces. The same can be said of chlorine. The elimination of sodium and chlorine

in the urine is increased when large amounts of these elements are ingested, by constipation, and by high water intake. In the cow, much more potassium is often excreted in the urine than in the faeces, but with rations characterised by the predominance of mineral acids, it was excreted in greater proportions in the faeces.

Cows excrete nearly all the calcium in the faeces, but if mineral acids predominate in the ration the quantity of calcium excreted in the urine may be slightly increased. There is always more magnesium than calcium in the urine, but the proportion in the faeces is usually four times that in the urine.

The phosphorus excretion is very similarly distributed to that of calcium, except that the phosphorus in the urine may be much increased by general physiological disturbance. Normally, 3 or 4 times as much sulphur is excreted in the faeces than in the urine, but, if large quantities are ingested, the sulphur content of the urine may be equal to that of the faeces.

Apparently, supplements of food or salts (sodium chloride, calcium carbonate or precipitated phosphate) have no effect on the quantity or composition of the milk.

No evident affect on the retention of mineral elements can be traced to variations in the ratio between acids and basic mineral elements as found in normal cow rations. A negative metabolism of the minerals may mean that a sufficiency was not ingested or that reserves previously accumulated were eliminated in the presence of a continuously superabundant ingestion. A negative and positive metabolism may, under certain circumstances, be only comparatively unimportant fluctuations in considerable reserves.

The nitrogen compounds in rations containing alfalfa hay are more digestible than the nitrogen compounds in rations containing clover hay; they are more completely absorbed by the intestine, but are more largely eliminated in the urine. The greater digestibility of the nitrogen in alfalfa, then, apparently does not show a corresponding nutritive superiority. The percentages of utilisation of the nitrogen compounds in the clover and alfalfa rations were the same. The deficient utilisation of the mineral elements by cows is of practical importance in the malnutrition of the bones of cattle, which is not uncommon after dry seasons and in over-stocked meadows, especially in regions with poor sandy soils or those of granitic origin, especially if these are exhausted by prolonged cultivation and insufficient manuring. This, again, probably implies the fairly common fact that, after a year of forced milk production, the cows quite often do not calve and numerous cows fed for high production do not maintain a high yield during consecutive lactation periods; it is probably one of the causes that contribute to the usual decrease in the milk yield as the lactaction period is prolonged. The most important observation arising out of this work is that under no circumstances was it possible to obtain an accumulation of calcium or a conservation of calcium metabolism in good milkers. It may be admitted, though it is not proved, that cows can

maintain a calcium equilibrium during a less abundant production of milk, but it is not known in what proportion the yield should be less in order to maintain the calcium equilibrium.

II. — This work shows that a heavy milker obtains the mineral constituents (especially the calcium) from the skeleton and that the cow cannot utilise a large proportion of the minerals in the food even when the basal ration is supplemented with more soluble calcium compounds.

As in the preceding experiments, 6 Holstein cows were used that yielded more than the average, but not exceptionally so ; all the cows were in their first lactation period. Each cow was fed for two experimental periods of 20 days, separated by an interval of 10 days during which the rations which were to be fed during the second period were adapted to their individual peculiarities. In 4 of the 12 periods, the number of days had to be decreased, on account of the irregular behaviour of the animals. In the first period, the basal ration per head per day was : — 11 lb. maize meal + 5 lb. nitrogenous concentrate. The average nutritive ratio was ; 1 : 5.72. In the second period, the alfalfa hay was increased to 18 lb. per day in order to satisfy the cows' appetite ; this, together with a change in the chemical composition of the alfalfa reduced the nutritive ratio to 1 : 4.5. With 3 of the cows, nothing was added to the basal ration during the first period, but, during the second period, they were given a supplement of calcium lactate (from 55.6 to 111.252 gm. per head per day according to how much the animal could take). The other 3 cows were given 70 gm. of precipitated bone flour per head per day during the first period and 40 gm. of calcium chloride during the second. The rations were those used for high milk production, except that succulent matter such as silage and roots was absent. The average daily production of milk was 47.2 lb. per head during the first period and 49.9 lb. during the second.

The data regarding each cow are given in a series of 16 tables and some of the most important figures are quoted in Table II see 482.

The results can be summarised as follows :—

The administration of precipitated calcium phosphate to cows when milking heavily and in periods characterised by the output of calcium in greater quantity than that assimilated, appears to result in the retention of appreciable quantities of the supplementary calcium and phosphorus, but the utilisation was very insufficient ; in fact, the mineral metabolism was usually characterised by a lack of economic utilisation of these constituents of the ration. Calcium lactate and calcium chloride were not assimilated, though the chlorine of the calcium chloride apparently was assimilated to a slight extent and led to an increased assimilation of the sodium in the ration. The different utilisation of the mineral constituents due to changes in the ration were in harmony with the nature of the change, i. e., an increased intake of an element was followed by an increased accumulation or a decreased loss of this nutrient but the response was usually so slight in comparison with the importance of the amount ingested, that it shows that the mineral metabolism of a well-fed good milch cow is not closely and directly dependent on the mineral constituents of the ration,

but that its nature is determined, under normal conditions, firstly by the inherited impulse to secrete milk, secondly by the mineral food reserves of the animal body, and thirdly by the food supply.

The most important result of this experiment showed that the limited utilisation of mineral food, particularly of calcium compounds, is not primarily determined by their solubility.

Common salt, at the rate of 42 gm. per head per day, is sufficient for sodium accumulation, but provides insufficient chlorine. Chlorine was not accumulated until it was given as a supplement in the form of calcium chloride.

The metabolism of potassium shows that a ration should contain abundance of roughage in order to maintain the metabolism of that element, that is, unless silage is used it is not always possible to conserve the potassium reserves of the organism, but it is true that under certain circumstances it cannot be ascertained whether a negative potassium metabolism means an actual lack of that element in the ration or simply unimportant fluctuations in the body reserve.

In this experiment, the ingestion of sufficient protein to provide nitrogen accumulation did not suffice to conserve the sulphur equilibrium. In spite of a general harmony in the metabolism of both sulphur and nitrogen, such as might be expected from their combination in the proteins of the food, there is a certain independence in the metabolism of these two elements.

In spite of a superabundance of calcium, magnesium and phosphorus in the rations, the metabolism, of calcium and phosphorus was negative in every case, while with magnesium 11 metabolisms out of 12 were negative.

Two of the chief facts that determine how sodium, potassium and chlorine are eliminated are their ready solubility and the length of time the food residues remain in the digestive apparatus. The chlorine of the calcium chloride was eliminated in the urine and the calcium in the faeces. The calcium and phosphorus were almost entirely eliminated in the faeces; the urine contains very little of either of them, but milk contains large amounts of both (always more calcium than phosphorus) and a larger proportion of the phosphorus than of the calcium in the food.

Magnesium was excreted in the urine in much greater quantities than either phosphorus or calcium. In 8 out of 12 cases, more magnesium was eliminated in the urine than in the milk; in 11 out of 12 cases the total excretion of magnesium was greater than the amount supplied. Similarly, sulphur in every case was eliminated in greater quantities in the urine than in the milk; in 11 out of 12 cases the quantity excreted was greater than that ingested. The quantity of sulphur ingested has a great influence on the distribution between the urine and faeces of the sulphur excreted.

The quantity of nitrogen retained depends closely on the amount ingested, but is not closely connected with mineral metabolism. An increased ingestion of nitrogen, up to a certain limit, causes a proportionate increase in retention and this increase is in proportion to the total quantity of nitrogen excreted in the urine.

441 – **Contribution to the Physiology of Calcium and Phosphorus Metabolism in Relation to Milk Secretion.** — Meigs., E. B., Blatherwick, N. R. and Cary, C. A., in the *Journal of Biological Chemistry*, Vol. XXXVII, No. 1, pp. 1-75 + 4 Fig. Baltimore, January, 1919.

Work carried out by the Dairy Division of the U. S. Department of Agriculture. A description and a discussion are given of experiments carried out with 15 milch cows and in which the phosphorus content and, in some cases, the calcium content of the blood were estimated at intervals during the periods of normal growth, gestation and lactation or during shorter periods under experimental conditions.

Two milkers and two dry cows were used for studying the precursors in the blood plasma of the phosphorus and fat in the milk. The method used was to obtain approximately simultaneous samples of blood either from the jugular vein or from the subcutaneous abdominal vein and to estimate the total phosphorus, the phosphatids and inorganic phosphorus in the blood and plasma of the samples.

The blood in the jugular vein had not passed through the mammary glands, while that in the subcutaneous abdominal vein had passed through them.

When the mammary gland was active and the experiment made without disturbing the animal too much, there were less phosphatids in the abdominal plasma than in the jugular plasma. No essential differences were observed in the inorganic phosphorus content of the plasma of milking and dry cows, in both of which the milk vein contained more than the jugular vein. It was impossible to show the existence in the plasma of any other phosphorus compounds save phosphatids and inorganic phosphorus.

The following conclusions were reached : — The fat and phosphorus in the milk are derived from some phosphatid (one or several) present in the blood. This phosphatid is converted in the cells of the mammary gland into an inorganic phosphate and a neutral fat ; it yields 2.5 or more parts of phosphorus to 45 parts of fat. As the milk only contains about 1 part of phosphorus to 45 of fat, about 60 % of the phosphorus that enters the mammary gland as the phosphatid that precedes the milk fat, must return to the blood as an inorganic phosphate. A slight psychological disturbance is sufficient to stop the absorption of the phosphatid by the mammary gland. The speed with which the phosphatid is absorbed explains the daily production of the fat in the milk. If this was derived, even only in part, from the fat in the blood, it would be difficult to explain how the inorganic phosphorus returns to the blood.

The relation between the age and the quantity of phosphorus in the blood was studied in 5 cows. During the first few days after birth, the phosphorus contained in the blood corpuscles was about double that in older animals, but the difference rapidy diminished and at 4 months was hardly perceptible. The phosphatid in the plasma of newly-born calves was at first present in minimum quantity, then gradually increased during the first year. The inorganic phosphorus in the plasma was fairly high at birth, attained its maximum at 6 months, then decreased.

Two cows giving their maximum yield of milk were used to study the effect of a decreased weight of food on the phosphorus of the blood. The total phosphorus in both blood and plasma, the phosphatid and the inorganic phosphorus in the plasma, the total phosphorus in the corpuscles and the relative volume of the corpuscles all diminished during the period of reduced feeding and revert to their previous quantity when abundant food is given again. During the reduced feeding there was a fairly clear inverse ratio between the concentration of the phosphatid in the blood and the daily yield of milk. The authors explain this by supposing that the phosphatid was introduced into the blood during that period in an almost constant proportion and that. consequently, its concentration in the blood varied inversely to the speed at which it was excreted in the milk.

The administration of disodium phosphate with the food tends to increase the phosphate concentration in the plasma, while the administration of calcium chloride tends to diminish it. This latter fact can be explained by the well-known effect of the ingestion of calcium on the excretion of phosphorus.

The phosphorus content of the blood and plasma probably diminishes towards the end of gestation, even if increased phosphates are given in the ration. Possibly in-calf cows are able to utilise a greater quantity of phosphates than is usually given in the food.

During the first month of lactation, the phosphatid of the plasma tends strongly to increase, then remains at a relatively high amount thoughout the entire lactation period. This phenomenon was largely independent of the food, and the authors think it is connected with the tendency of the fats of the reserve tissues to pass into the circulation at the beginning of lactation.

The concentration of the calcium in the blood is very constant ; slight increases were obtained by giving calcium chloride in the food. The authors consider that the chief factor that influences the calcium content of the blood is acidosis.

FEEDS AND FEEDING

442 – **Apple Cake or Powdered Apple Refuse.** — REMONDINO, C., in *Il Coltivatore*, Year LXV, No. 34, pp. 759-760. Casale Monferrato, December 10, 1919.

In the province of Cuneo, Italy, a co-operative society has been established for the preparation of fruits, particularly in the dry state, by means of the best modern methods. This in done in the factory opened in Cuneo by thermo-electric machines.

In preparing apples, they are sorted into 3 grades : —

1) fine and large ; 2) medium ; 3) small or green, or beginning to spoil. The apples of the first grade are peeled, the heart is removed and they are sliced, dried and packed in boxes.

The second grade apples are used for cider making, which is then either consumed or passed over fresh pomace to make " piquette " ('small' cider) or fermented to make dry cider.

The third grade apples are mixed with the by-products of the other grades, dried and ground, thus giving a powder well suited for rearing stock

It is given to calves at the rate of a pound per head per day, and when tested practically has always given excellent results. This apple powder has the following percentage composition: — Water, 8.48; fats, 3.88; ash, 7.18; nitrogenous matter, 7; fibre, 19.05; and nitrogen-free extract, 51.41 %.

443 – **The English Thoroughbred in Italy.** — Moreschi B., in *L'Italia agricola*, Year 56, No. 10, pp. 305-316 + 3 Figs. Piacenza, October 15, 1919. HORSES

There are not many more than 30 breeders of English thoroughbreds in Italy and over two-thirds of these are in Upper Italy.

In the spring of 1919, amongst the State stallions, there were 77 English pure-breeds, of which 41 (55 %) were born in Italy and 36 came from abroad — 24 from England, 11 from France and 1 from America. The English thoroughbred represented just over 7 % of the 1106 State stallions that were in use in 1919.

There has been a rapid and progressive diminution in the proportion of thoroughbreds in the deposits :— 14.16 % in 1890; 13.07 % in 1899; 12.11 % in 1904; 11.20 % in 1912; 10.28 % in 1914.

The 77 that were employed in 1919 were distributed as follows to the various deposits: — Crema, 4; Ferrara, 6; Reggio Emilia, 17; Pisa, 18; Santa Maria di Capua, 13; Catania, 19. The deposit at Ozieri (province of Sassari), which serves Sardinia, has none now, as horse-breeding in the island has a decided tendency towards the Arab type, which has always given excellent results.

Thoroughbred horses are less common in northern Italy, more common in central Italy and still more common in southern Italy and Sicily. In Sicily, they are used for producing Anglo-Arabs, which are said to be more robust than the Arab and less exacting than the English horses, with true and harmonious proportions and large, well-attached muscles.

444 – **The Escutcheon of Dairy Cows.** — Hooper, J. J., (Kentucky Experiment Station) in the *Breeders' Gazette*, Vol. 76, No. 2, pp. 52-53. Chicago, July 1, 1919. CATTLE

Short discussion on the shape of the escutcheon of 1019 dairy cattle examined by the author and J. W. Whitehouse at the Kentucky Agricultural Station. They found that the "Flandrine" type of Guénon is dominant in the Holsteins (66 %), Guernseys (54 %), Kerry (68 %) and in the few Ayrshires examined (92%) whilst the "Selvedge" type was commoner in the Jersey (40 %). The average of the yields of registered Jersey cows shows that cows with a shape of escutcheon theoretically corresponding to a lower milk yield, whether of the "Flandrine" or "Selvedge" type, give more milk and butter than cows with an escutcheon theoretically of the first class of the corresponding type. The author concludes that the escutcheon is more or less a characteristic of the breed and that its size and shape are of little if any importance in selecting dairy cattle.

445 – **Sheep Breeding in Hanover, Germany.** — Koster, in the *Mitteilungen der Deutschen Landwirtschafts-Gesellschaft*, No. 23, pp. 319-324. Berlin, June 7, 1919. SHEEP

Sheep fattening has long been an important branch of stock rearing in the Leine valley, Germany. As the production of wool and meat

are of great importance in Germany now, the author has collected the results obtained in Hanover with suitable crosses between the local breed (Leineschaf) and an English mutton breed. The Leine sheep is a good milker, wich can feed its lambs for 6 months or more, but its wool is coarse and scanty and the lambs are not early maturing. The cross-bred lambs, however, can be fattened after the 10th. week, if the proper precautions are taken for fattening such young animals. The results obtained by crossing with the Oxford are given in Table I. The total fattening period can be divided, according to the results obtained, into three sub-periods, the first of 12 weeks, the second of 8 and the third of 9, during which the gain in weight is according to the ratio 3 : 2 : 1.

During the same experiments, the gains in weight were notified of 6 rams, 6 wethers and 6 ewes as well as of 6 rams respectjvely belonging to the Oxford, Hampshire and common breeds.

The results are given in Table II.

TABLE II. — *Gain in weight of various sheep.*

	Initial weight	Days of fattening	Gain in weight	Gain per head per day
	kg.		kg.	kg.
6 rams	67	140	218	0.26
6 wethers	67	140	200	0.235
6 ewes	69	140	192	0.25
6 Oxford rams	—	105	171	0.28
6 Hampshire rams	—	105	167	0.265
6 common rams	—	140	218	0.26

TABLE III. — *Wool produced and scouring results from the cross Leine Dishley × Merino (in kg.)*

	1916	1917	1918	1919

Scoured wool per sheep	1.46	1.65	1.51	1.75	
Value of wool, in francs	10.9	13.9	16.27	29.675	

As regards the results obtained in improving the quality and yield of the wool, the results given in Table III were obtained by crossing the local Leine with the Merino-Dishley.

The results in Table III show that by 1919 the third quality wool which is characteristic of the Leine breed had almost completely disappeared, thus showing the improving influence of the Merino-Dishley cross on the quality of the wool in successive crosses. As well as these general results, those relating to each animal are given (Table IV) and show the large individual variations.

The author also deals with the market demand for lambs for fattening and wool-producing at the age of 3-4 months ; they are bought by farmers with good intensive pastures where they are fattened up to 60-70 kg., with a yield of wool that is normally 5 kg.

446 – **Dried Carrots as Food for Pigs.** — Badoux, F., in *La Terre Vandoise*, Year XI, N. 47, pp. 420-421. Lausanne, November 22, 1919. PIGS

The author was asked by the "Société Vandoise d'Agriculture" to test the food value of dried carrots for pigs. Three groups of pigs were selected and group A served as control, B received a medium ration of dried carrots and C received a heavy ration. The rations always contained the same amount of digestible nutrients; they were as follows:—

Foods	Group A 1st and 2nd week	Group B		Group C	
		1st week	2nd week	1st week	2nd week
Potatoes . . . . . kg.	2.000	1.600	2.000	1.300	2.000
Maize . . . . . »	0.450	0.500	0.250	0.550	0.130

Barley . . . . . »	0.200	0.200	0.200	0.200	0.100
Rye . . . . . »	0.100	0.100	0.100	0.100	0.100
Cake . . . . . »	0.100	0.050	0.100	0.050	0.070
Dried carrots . . . . . »	—	0.200	0.500	0.300	1.000
Nutritive ratio . . .	1 : 6.25	1 : 6.25	1 : 6.23	1 : 6.25	1 : 6.24

The cost of the ration for each of the three groups was respectively 92, 93 and 92.5 centimes per day per head with the following prices per kilo: Potatoes, 15 ct.; maize, 50 ct.; haricots, 53 ct.; barley, 64 ct.; rye, 60 ct.; cake, 50 ct.; dried carrots, 32 ct.

The increase in live weight was 230 gm. per head per day and was equal in the three groups.

The results were satisfactory on the whole and show that dried carrots are suitable for fattening pigs, especially as, regarding the experimental groups (contrary to the control group), the rule was intentionaly neglected that once a fattening ration is chosen it should not be changed, otherwise the utilisation of the nutrients greatly decreases.

Light-coloured dried carrots are much richer in food material than dark-coloured ones, and contain an average of: Protein, 7.1 %; fat, 1.1 %; sugars, 34.5 %; moisture, 21.8 %. Pigs are very fond of them and the best ration is 500 gm. for pigs weighing 50 kg.

447 – **Citrus Peel as Food for Pigs.** — Allen, R. S., in the *Maryland State College of Agriculture, Agricultural Experiment Station, Bulletin* 227, pp. 193-202. Maryland, March, 1919.

Garbage constitutes a good food for pigs, chickens and sheep but chiefly for pigs. It usually consists of 16 % of animal matter, 70 % of vegetable matter, 5 % of unutilisable matter, and usually contains approximately 70 % of water, 20 % of solid matter, 3.5 % of fat, 1.5 % of bone, and 5 % of useless matter. The best rate at which to feed it to pigs is 20 lb., per head per day and, for hygienic reasons, it should be cooked first.

Pigs will not eat the raw peel of citrus fruits, and it is generally supposed that cooking leads to the formation of a substance poisonous to pigs. The author was asked by the National Research Council to find whether this belief is correct, and accordingly experimented on 4 groups of 3 pigs each at the Maryland Experiment Station. Each group was given maize flour, linseed cake + tankage in the proportions of 94 : 3 : 3. One group received no other food and served as control ; the others were respectively given large quantities of the cooked peel of oranges, lemons and grape fruit. The peel was about ⅓ of the total food consumed. The test with the group given grape fruit had to be stopped after 40 days, as no more was available ; that with the two other groups lasted 90 days. A table gives the weight of the animals every 10 days. No toxic effects were observed. The control group ate 10.5 lb. of food for each lb. of weight gained ; the group that ate orange peel ate 6.7 lb. of the basal ration and the group that ate lemon peel ate 5.7 lb. If this peel is available it is best used by cooking it and feeding it to pigs.

POULTRY

448 – **Ostriches in North Africa.** — Rivière, C., in the *Revue agricole de l'Afrique du Nord*, Year XVIII, No. 25, pp. 51-54. Algiers, January 16, 1920.

The Berbery ostrich (*Struthio camelus* Lin.), the finest existing ostrich, belongs exclusively to North Africa. Attempts to domesticate it have long been made in that region and the author sums up the attempts made from 1868 up to the present, attempts which have all failed.

The failures in Algeria and elsewhere are largely due to the bad origin of the breeding animals. Then the marine climate of North Africa, especially on the littoral, where the runs had been established, is apparently unsuitable for the production of fine feathers.

The right place for the industrial exploitation of the ostrich in North Africa is the extensive steppe regions whose air and soil are both dry, where the grassy covering has some temporary value ; there it is that the plumage acquires all its qualities and the bird keeps its vigour, for damp and bad weather are injurious to it.

In 1888, the author had the idea of populating the southern regions on the Sahara border by transporting there all the breeding pairs from the experiment gardens and ostrich farms in Algeria, and confiding them to the care of the Djemmas (a sort of administrative council of the southern tribes), who would have reared them by changing their pastures. However, this idea never matured on account of financial difficulties.

As regards the state of the ostrich farms in Algeria, Tunisia, Morocco and even in Madagascar (1), the author affirms that "' for many years now, in spite of failure upon failure, they remain still at the stage of hope and..... expense ".

The unfavourable conditions that apparently are opposed to economic rearing in all North Africa are summarised by the author as follows :

(1) For ostrich-rearing in Tunisia, see *R.*, 1911, No. 1483 ; in Madagascar, see *R.*, 1910 p. 144 ; *R.*, May, 1911, No. 1484 ; *R.* August, 1914, No. 757. (*Ed.*)

The cock Berbery ostrich has long white plumes in the wings and tail and these are the most in demand. Those of the hen, generally grey, are much less valuable.

Egg-laying only takes place in periods, every 2 days, in winter and summer. There are from 30 to 40 and even as many as 60 eggs. The eggs are usually hatched by both the parents, but the cock often takes a more active part in incubation, which lasts from 42 to 45 days and good hatchings give a dozen chicks which are easily reared by the parents. Thus, many eggs are lost and, unfortunately the eggs of this race cannot be hatched artificially; the rapid development of ostrich farming in South Africa is largely due to the fact that the eggs of the ostrich there can easily be incubated artificially.

The existing difficulties in the way of ostrich farming are :

1) The difficulty, even the impossibility, of obtaining breeding animals of a good type.

2) The difficulty of using artificial incubation with the Berbery race.

3) The difficulty of cheap stabling and maintaining a good sized flock which, before the war, cost 170 francs per pair per year (in the Cape, the annual gross revenue was 150 to 200 fr. per pair).

4) The income is only from the feathers ; the sale of the eggs for food is of slight importance.

5) The food for a fine breeding pair consists per day, of 500-600 gm. of various grains, about 20 kg. of green food and 8 litres of water.

It would be difficult to realise these conditions in the steppe regions, where only the dry climate is favourable to the feather-bearing ostrich.

The necessary technique for obtaining a good yield by natural incubation has been accurately ascertained at the Algiers Experimental Garden.

The author gives no definite conclusion and limits himself to explaining the situation, but past experience seems definitely against practical ostrich farming in North Africa.

449 – **Trial of a System Consisting in Keeping Two Queens in Each Hive.** — SLADEN, F. W., in the *Agricultural Gazette of Canada, Dominion Ministry of Agriculture*, Vol. 6, No. 2, pp. 140-142 + 3 Fig.s Ottawa, February, 1919. BEE-KEEPING

As it would be of great utility to find an efficacious method for preventing swarming without too much work, the author tried to solve the problem by keeping 2 queens in each hive for 11 months of the year. He found that this is a practical method and will try it again in 1919.

Two young queens, separated by a double partition of wire gauze, were wintered in a hive in a cellar from 1917-1918. When the dandelion flowered, the bees and queen from one side of the gauze were removed to another hive ; in this way swarming was avoided and the two queens gave a uniform and increasing production of young bees, thanks to which, two strong hives were obtained in time for the flowering of the clover. The number of bees was much greater than the number which began the season with one queen. These bees yielded 480 lb. of honey.

In order to avoid swarming when the clover flowers, and to obtain two queens again in each hive (all the following operations were carried out in

several colonies), the author removed the old queen from the brood chamber when the clover flowered and, 8 days later, destroyed all the royal cells save two, one on each side of the metal gauze. A special porch fixed in front of the hive separated the entrances to each half by 8 inches. This was done to avoid the possibility that the queens leaving their cells might meet on returning from their nuptial flight. These hives did not swarm.

450 – **Sizes of Frames for Hives.** — JUNGFLEISCH, C., in *L'Apiculteur*, Year 64, No. 2, pp. 33-34. Paris, February, 1920.

The arrangement of the hive depends on the purpose for which it is intended. To obtain honey in sections, the frames must be low, so as to force the bee to climb up. High frames, or rather frames superimposed vertically, are better suited for honey for extraction, as they help the bee to store its provisions above the brood chamber, as it tends to do naturally.

In rich honey-districts very large frames are said to be needed, while small frames suit poor districts. But the author points out that the conclusion is erroneous, since large hives with large numbers of bees are wanted everywhere and while the hives can be numerous in rich districts, they must inevitably be few in number in poor districts.

Some time has passed since a Bee-Keeping Congress tried, without success, to clear up the question as to the size of the frames. However, there are certain shapes which may be described as classic: the low frame, 30 × 40 cm.; the high frame, 30 × 40 cm.; the square frame, 33 × 33 and 35 × 35 cm; and the frame 42 × 27 cm., very common in France owing to the importation of American hives. All these frames are large (about 12 sq. decimetres in area) and are only used for the brood chamber; the frames of the sections are only ½ or ⅓ the height of the hive frames. The divisible hive, with superimposed sections, which has become more common of late, has led to the adoption of smaller frames which may be either high or low: 35 × 25 cm.; 30 × 30 cm.; 30 × 25 cm.; etc. All these refer to inside dimensions in centimetres.

Again, bee keepers are not agreed as to how the frames should be measured. The internal dimensions are nearly always given, but the author observes that as the external dimensions alone fix the size of the hives, extractors, etc., they are the only ones that should be given.

451 – **The Boulonnaise Hive with P. Chiris Frames.** — HIBON, C., in *L'Apiculteur*, Year 64, No. 2, pp. 35-36 + 2 Figs. Paris, February, 1920.

This hive only differs from other mobile hives by the arrangement of its brood chamber. The hive consists of four panels mounted on a board and, the 2 vertical gables to which are nailed the board and the pont and rear walls, inclined at the same angle as the P. CHIRIS frame _/ adopted for the brood chamber. Each of the inclined walls stops 25 mm. from the board, but is continued by a small, movable plank which slips along the outside of the wall and rests on the board. In front, this small plank does not come down to the board, but rests on a notched stick in which is a hole to allow the bees to pass.

The board has two slopes, inclined in such a way as to throw the debris falling from the combs towards the movable planks in the front and rear, so that cleaning is easily carried out by lifting these planks. The median ridge carries a metal rack which keeps the bottom of the frames in position, the tops being kept in place by bent nails fastened in notches on the edges of the walls.

The roof consists of a rigid panel, with tongued joins to prevent warping and fits on the body of the hive, directly on the walls, which have no ledges.

The brood chamber contains 10 frames with some 8 sq. decimetres of available surface. The capacity is not much more than 30 litres. In order to adapt the hive body to the square VOIRNOT, it was found necessary to make it of these dimensions.

452 - **To Preserve Frames from Moth.** — PATAY, in *L'Apiculteur*, Year 64, No. 1, p. 30 Paris, January, 1920.

To preserve sections not in use, they are placed in a well-ventilated room; in each section, between the frames, is placed a small piece of absorbent cotton wool soaked with cinnamon oil. The author kept his sections perfectly in this way for three years. The bees seem to be unaffected by the smell of the oil. The author intends to place the cotton wool in all the coverings and roofs. If a swarm dies, the combs will be found intact and free from the larvae or moths of *Galleria mellonella*. If this is successful, it will provide a valuable means of defense for a weak swarm. Very little oil is required for an entire apiary.

453 - **Ants as Enemies of Bees and Hives.** — TINAYRE, J., in *L'Apiculteur*, Year 63, No. 11, p. 267. Paris, November, 1919.

Most treatises on apiculture suggest that ants are more a nuisance than harmful to bees. The author, however, has found that hives placed near woods are exposed to dangerous invasions by ants, especially in early spring. Unless closely watched, the ants, starved after their winter seclusion, will impoverish the hives in numbers and food.

It is difficult to deal with ants when the hives are near a wood, for as soon as one ant-heap is destroyed another is formed. They can, however, be opened with a pick and burnt out with paraffin. In addition, the base of the supports of the hives should be surrounded by fine wood ashes, as ants cannot climb up this; the ashes should be renewed after the slightest rain.

FARM ENGINEERING.

AGRICULTURAL MACHINERY AND IMPLEMENTS

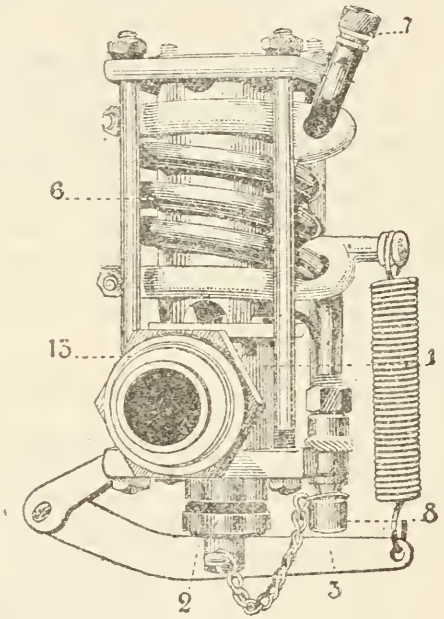
454 - **Protection of Tractors against Freezing.** — PASSELÈGUE, G., in the *Journal d'Agriculture pratique*, Year LXXXIV, New Series, Vol. 33, No. 4, pp. 72-73. Paris, January 22, 1920.

Serious accidents, such as cracked radiatiors or cracked water-jackets of the cylinders — accidents that not only mean expensive repairs but make the machine unusable for some time — are caused by the freezing of the cooling water of tractor or automobile engines.

The simplest way to avoid this is to empty the radiator each time that it freezes or threatens to freeze, provided that there is no doubt about it.

It has been suggested that the freezing point should be lowered by mixing the radiator water with chemicals like glycerin, methyl alcohol and calcium chloride. Glycerin has the disadvantage of fouling the radiator tubes and pump, and diminishing the cooling power of the radiator. Methyl alcohol gradually evaporates, as it boils at 80° C. Calcium chloride which gives the best results, used at the rate of 220 gm. per litre of water, lowers the freezing point to -10° C.

The engineer M. F. CESBRON, of 37, rue de Brissac, Angers (Maine-et-Loire), has invented an apparatus called the *Frigon* (see figure), which



Apparatus for protecting a tractor radiator against freezing.

automatically empties the radiator before the water freezes. The apparatus, which is quite small (14.5 × 10.4 cm.), communicates with the radiator at its lowest point by the junction 13, which opens into a chamber 1, closed at its lower end by valve 2, kept tight on its seating by a spring pulling on the lever 3.

The apparatus includes a copper coil 6, with an internal diameter of 4 mm. ; the lower end of the coil is closed by a piston whose shoulder rests on the lever 3.

To put the machine ready for action, the stopper 7 is screwed up until the water begins to drip from the end of the coil. This shows that

the coil, which is filled through a feed communicating with the chamber 1, is full of water and that the apparatus is ready.

As the temperature of the air falls, the water in the coil, on account of its small volume (5 cc.) and the great conductivity of the copper wall, cools more rapidly than the radiator, so that the water in the coil is frozen while that in the radiator is still liquid. The increase in volume due to the water freezing in the coil pushes the piston which, acting on the lever 3, opens the valve 2 and thus empties the radiator.

Experiments carried out by M. RINGELMANN at the " Station d'Essais de Machines " have shown that the apparatus works when the radiator water is still at 3° C. The water freezing in the coil moves the piston a distance of from 2-4 mm. The apparatus, placed on the radiator of a 17 H. P. MORS automobile, emptied all the water that could be emptied by the waste tap before it was frozen.

To provide for the safety of pumps, tanks, etc. that might be injured by freezing, this apparatus, which when placed in position requires no further attention, could be used.

455 – **Ploughs for Mechanical Cultivation.** — DUVAL, G., in *La Vie Agricole et Rurale*, Year IX, No. 45, pp. 331-334 + 5 Fig. Paris, November 8, 1919.

AUTOMATIC LIFT AND EARTHING. — Mechanical cultivation, which enables and even requires the use of gang ploughs, has given the maker the problem of lifting and earthing the ploughs automatically. Some strong, simple mechanism was required, as well as a movement that requires no effort or attention on the part of the driver, who is already sufficiently occupied with driving and has, in addition, just at the moment when he should set the mechanism in motion, to turn correctly and come accurately back to the furrow.

The " Motoculture Week " at Senlis provided the chance for the study of a large number of ploughs with automatic lifts; the system on which they work is described succintly below :

AMERICAN PLOUGHS FOR PLOUGHING IN RIDGES. — The American solution can be summarised as follows :

The frame *B* (Fig. 1), to which the gang is fixed, is supported in front by wheels, at least one of which plays a part in the operation. The wheel *R* is mounted loose on the axle *E* on a hub *C* of large diameter. A drum *T* is keyed on the axle inside the hub *C* ; it is provided with a button *a* to which one of the ends of the rod *b* is attached, the other end being attached to a certain point of the frame *B*.

If the frame *B* is in the low position and if it be supposed for the moment that the drum *T* is momentarily fastened to the ring *C*, when the wheel *R* turns the connecting rod *b*, the frame *B* will be brought to the position *b'* and *B'*, and the plough will be lifted. The mechanism should hold the frame in this position until a second movement allows it to fall or even mechanically brings it to the low position. Usually, a simple transmission acts on the wheeled back of the plough so as to change the level at which it runs compared with the frame, either by making the stay pivot round

a horizontal articulation or by making the stay slip on its support. The plough is lifted by placing the stay in a vertical position and moving the guide downwards; the reverse movement earths the plough. As the plough is fairly heavy, lifting is helped by the provision of springs which tighten as the plough earths and takes up part of the weight when the plough is lifted.

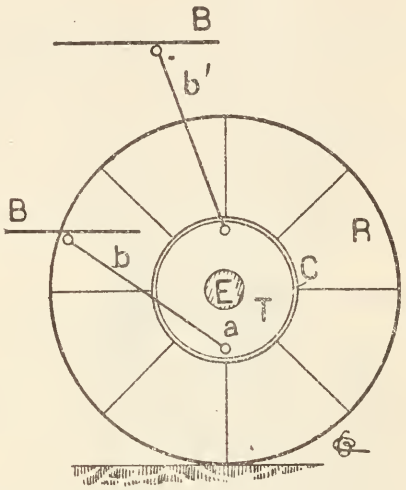


Fig. 1. — Scheme of the American plough.

The lift system on the OLIVER plough (Fig. 2) is made up as follows :

1) of a roller *G*, fixed on the frame *B* ;

2) of a cam *C*, of special shape, with a catch *V* pulled by spring towards the axle *E*, and provided with a circular notch *e* ;

3) of two rollers *g'* and *g* mounted on the jointed levers *a* and *c*, connected by the rod *b* ; a spring *R* tends to pull *g* towards the cam *C* ; they are separated by a lever *A*, through a small rod *d*, when a cord is pulled in the direction shown by the arrow.

4) of a rachet wheel *R*, fastened on the axle *E* of the front wheel.

When the apparatus is in the low position, the roller *g* is in the notch and presses on the end of the catch which then becomes disengaged from the rachet wheel. Everything is now free as far as the wheel is concerned. To lift the frame, the driver pulls the lever in the direction *f* ; the roller *g* is moved away from the cam, and the catch is pulled down by the spring *r*. The cam *C* turns and lifts the roller *G*, which moves to the position *G'*, carrying the frame with it, thus lifting the gang. A connecting rod transmits this movement to the rear wheel.

When the high position is reached, the roller *g'* enters the notch, pushes on the end of the catch *v* which is disengaged from the rachet wheel when the

disconnection is carried out. The roller g', held in the circular notch e by the spring R', forms a stop. On moving the lever A again, b is freed and the gang falls by its own weight, the roller g returns to its place in the notch and frees the bolt v ; the machine is now in the low position. This mechanism is simple and strong, and easily accessible, being uncovered. There is a slight disadvantage as the parts are not very near to the soil.

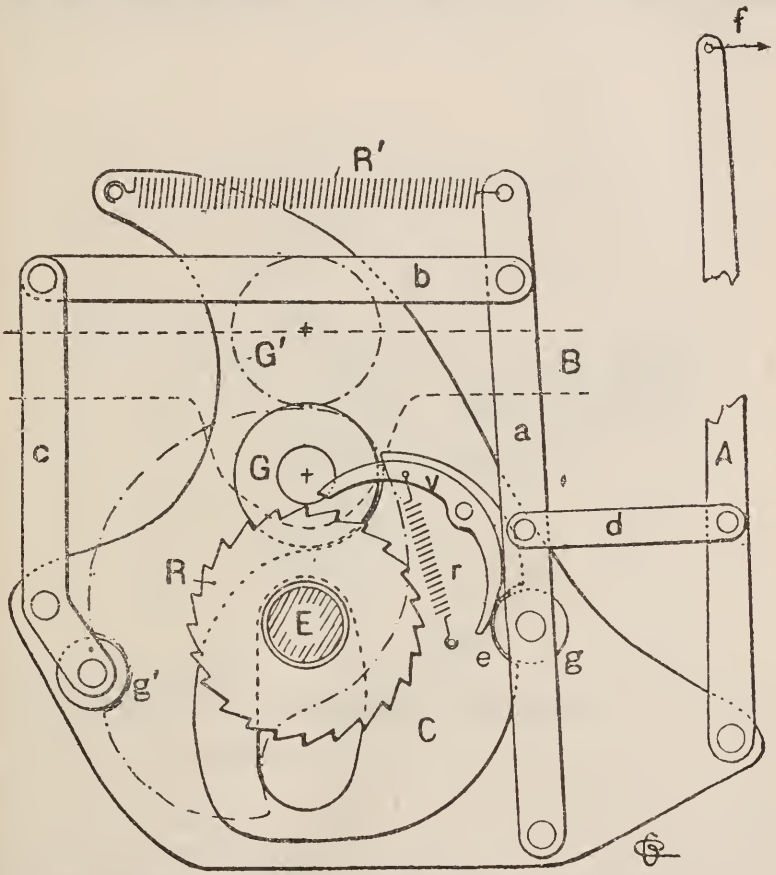

Fig. 2. — Mechanism of the OLIVER plough.

In the two-furrow, No. 7 OLIVER plough, lifting is carried out by an excentric toothed segment fixed on the frame. When the lever is moved, the segment meshes with the lantern-wheel fixed on the turf wheel. With a forward movement, the whole rotates round the cranked shaft that connects the frame and the wheels.

In the JOHN DEERE ploughs, the self-lift mechanism is of the same type as that shown in Figure 1. The frame B (Fig. 3) is attached to the wheel

R by the cranked shaft *EEb'*. The lever *a* on the drum *T* moves the rod *b* which presses, not on the frame *B*, but on the depth-regulating lever j, which is fastened to the frame by a bolt engaged in the appropriate notch of the sector *s*. When the lever *L* is pulled by the cord *x*, the roller *G* frees the catches *c'* and *c*, which jams the drum *T* to the ring *C* and thus with the wheel *R*, the frame passes from the low position *B* to the high position *B'* ; the rear is also moved by the pivotal motion of the " heel ".

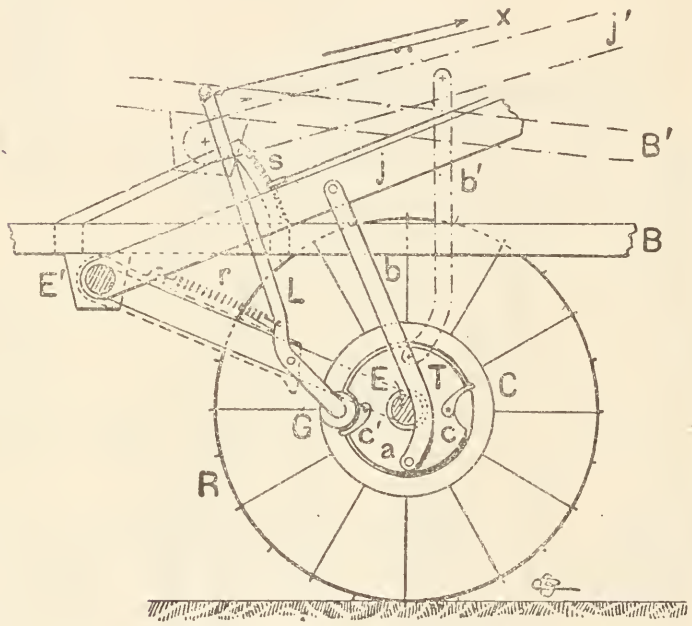

Fig. 3. — Mechanism of the JOHN DEERE plough.

Figure 4 shows the construction of the JOHN DEERE pawl and ratchet device. To avoid confusion, the ring *C*, which forms part of the wheel ; is shown in dots, the mechanism, of the drum *T* being shown in black lines. The ring *C* is provided internally with a series of circular notches that make it a sort of ratchet. At the right moment, a roller *g*, mounted on the rod *k* which commands the spring *r*, will slip into one of these notches; the articulation of *k* carries a pawl *c'*, keyed on the axle and when the pawl moves, it also moves *k* and *g*. A second rod *d*, with a pawl *c*, is keyed on the opposite side of the axle *E* ; *d* and *k* are joined by a small rod *b*. The drum *T* has two notches at the level of the catches *c* and *c'*. In the figure, the roller *G* is in the right hand notch, pulled by the spring *r* shown in Figure 3. It

pushes back the pawl *c* and *g* does not mesh with the ring *C*. If *L* is pushed, *G* moves away, frees *c*, and the spring *r* pushes the roller *g* in a notch of *C*; the device has operated and the crank has moved the lifting rod.

After 180 degrees are rotated, *G* moves into the second notch, pushes back the pawl *c'*, and frees the roller *g* of the ring and disengages the drum *x*, while holding up the plough until a fresh pull on L brings about meshing again, when the frame comes down to the low position after a rotation of 180 degrees, when the roller *G*, acting on *c*, again frees the drum, and so on.

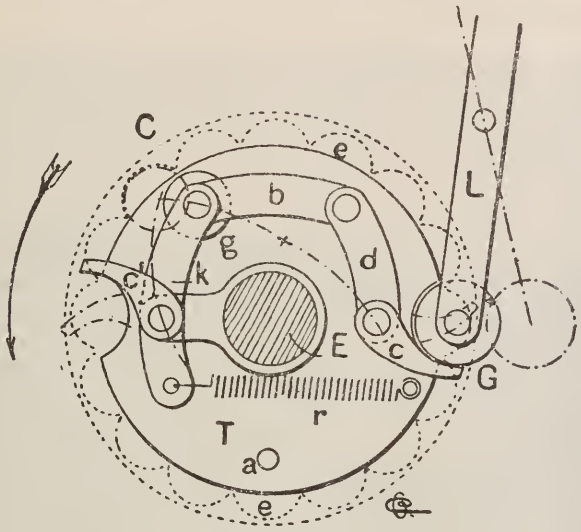

Fig. 4. — The John Deere click work.

Chain Mechanisms. — On the P. O. (Wallut), Grand Détour, Case and other ploughs, the self-lift operates by pushing forward the elbowed axle that joins the wheels and frame. To do this, a toothed pinion is mounted on the central part of the axle with which it is connected by a pawl and ratchet similar to that just described. This pinion turns continually, being driven through a chain by another, but smaller pinion mounted on the hub of the wheel.

When the rachet mechanism is put into action, the central part of the elbowed axle turns and pulls the wheels towards the gang, but as the resistance of the soil stops this, the inverse movement is produced, the central part of the axle-turning round the spindle of the wheel and, moving forward, lifting up the frame.

American Ploughs for Ploughing without Ridges. — At Senlis, the only ploughs of this type were two-wheeled ploughs with two independent bodies, one on the left and one on the right.

In the Moline Sulky plough, the end of the beams is kept at a fixed level, but, a little to the rear, is a bent shaft, which lifts or earths the ploughs.

The driver presses a pedal which acts on a friction cone in a drum mounted on the hub of the wheel, thus forcing it to turn with the wheel ; the drum bears a circular groove on which rolls a chain which, pulled in this way, turns the bent shaft. A similar arrangement is used in the horse sulky and enables it to be driven by a man with a disabled arm.

French Ploughs — Although the problem was considered much later in France than in America, some elegant solutions have been found. The number of the *Vie agricole et rurale* from which this article is abstracted, contains a description, by M. Coupan, of the self-lift devices of M. M. Dubois and Lefebre.

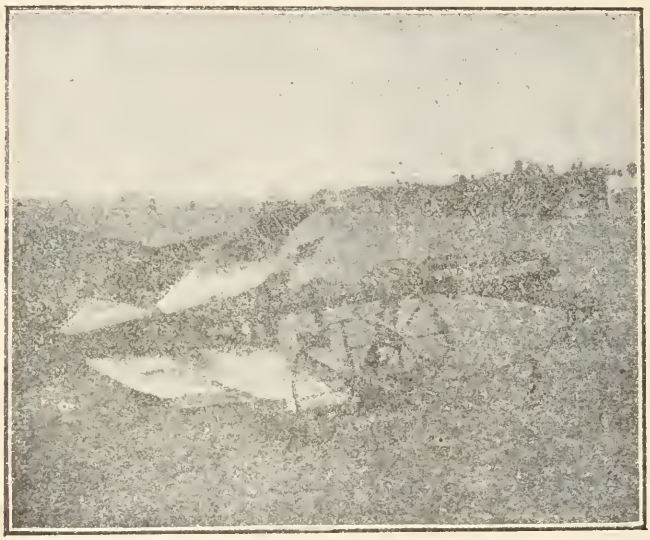

Fig. 5. — Filtz-Grivolas double brabant plough.

The " Etablissements Bajac " showed a turn-wrest plough with a special anti-balance device. This plough, which works with a motor windlass of the same firm, is characterised by a bearing axle capable of a large angular displacement around an axis transversal to the frame. This axle carries with it a toothed ring which gears with a second ring with internal teeth and fastened to the frame that supports the ploughs. Thus, when the axle moves in one direction, the frame is moved in the opposite direction. This device shifts the centre of gravity of the frame from the normal and gives great stability. When speed is changed, it makes earthing easier for in many cases only the tipping occurs.

The " Messidor " plough of the Etablissements Pétard, is a sort of Belgian gang plough that can be attached to any tractor. But the stays, instead of being in the same plane, are in two planes at 90° to each other, so that the gang can be changed by a rotation of a quarter of a circle. This is

done through a circular rack driven by a pinion worked by hand. In the rear this plough has a sort of rolling heel with two equal wheels running obliquely, one in the furrow and one on the turf but without a pawl and ratchet mechanism; the heel enables the machine to run backwards.

The new double brabant two-furrow plough of the *Société matérial de culture moderne* (Etablissements FILTZ-GRIVOLAS) has a massive " ecamoussure " (70 kg. for a total weight of 420 kg.) behind which is the two-wheeled axle. It will be seen from Figure 5 that this support is derived from the self-lift lever, but the two arms are continued by a part bent in front which moves in front of the sectors ; the ends are joined by two strong springs in front of the " ecamoussure ".

The drawing action affects the axle, which moves forward, tightening the springs more as the pull becomes greater ; tappets in suitable positions on the sectors limit the displacement and regulate the entrance. This plough enters the soil gradually, not suddenly. When the tractor stops at the end of the furrow, the springs pull the axle back, which lifts the beam, starts the lift and prepares the machine for turning. As the " ecamoussure " is carried far forward, the plough can be lifted and turned easily by a labourer of medium strength.

Two ploughs of this type were ploughing without ridges at Senlis, hauled by FILTZ tractors, one with a cable and the other with direct traction, a system of attachment being used that obviated turning. This device would be useful on horse brabant ploughs.

456 – **Damage of Seeds in Threshing.** — MARTINET G., in *La Terre Vaudoise*, Year XII, No. 10, pp. 78-79 + 1 Fig. Lausanne, March 6, 1920.

According as the season is more or less dry, the proportion of grains of wheat that are broken or simply cracked by the thresher is fairly large and not only leads to wastage but to deficient germination and plants that come up too thinly. The splitting of the grain is only detected when it is treated with copper sulphate, as the fissure stains blue. Split grains are obviously not sieved out in the machine and the large grains are the most likely ones to suffer.

When cereals were threshed with a flail, the cut wheat was left to ripen and dry in the field particularly oats, which were often left 2 or 3 weeks, the reason being to facilitate separation of the seed. The need for reducing the cost of harvesting has led to the neglect of this practice and the crop is too often brought in too early, before the straw is sufficiently dry, especially at the nodes. The remaining damp causes the heap to ferment too much and as well as spoiling the seed, not only in the case of oats, but also with naked seeds.

As the crop is not sufficiently dried, the action of the organs of the threshing machine has had to become more vigorous in order to separate the seed completely. Consequently, the drum has to revolve more quickly and the fittings of the drum and counter-drum are closer set. The beaters themselves, which were formerly wooden staves cased with iron or angle irons whose ridge was the sole active part, have given place in the modern

drums to beaters with oblique, very prominent grooves, so that the thresher would be almost like a crusher, did not the presence of the straw somewhat mitigate the violent action of the shelling organs on the grain.

The " English " beaters are suitable for wheat with soft seeds, but not hard or semi-hard seeds. In fact, some recent threshers of English make have beaters with less pronounced undulations and with the front part bevelled, and, in addition, the beater is often preceded by a plane, inclined portion which pulls the straw and ears less roughly towards the beater, the material being treated less roughly. In this respect, the angle iron and to a certain extent, the closed drum, act more or less in the same way.

The French makers fit the working part of the beaters in their machines with iron bands with fairly smooth longitudinal undulations, so that breakage is diminished or hardly occurs.

The makers, therefore, should study the subject, so as to avoid useless damage to the grain and straw . The author thinks that the French beater with an inclined plane is the type that should be adopted.

In threshing seed grain, it might be useful to adopt a light pre-thresher, with soft wooden beaters, which would separate the large grains for use as seed and would be followed by complete threshing with the ordinary drum placed immediately afterwards.

United Kingdom: 134288-134561. Motorploughs; 134293 Plough mould board.

United States: 1321248 Pulveriser; 1321367 Guide and depth regulator for ploughs; 1321551 Tractor plough; 1322066 Swingle-trees for disc-harrow; 1322455 Cultivator; 1323082-1323184-1324719 Garden ploughs; 1323481 Harrow suspended from a cart; 1323887 Disc-plough with sub-soiler.

MANURES AND MANURING. — *Canada:* 194796-195602 Process for making aluminium nitride.

New Zealand: 41071-41072-41073. Processes for manufacturing nitrates; 41074 Process for manufacturing calcium nitrate.

United States: 1322031-1324540 Manure spreaders: 1323674 Manure loader.

DRILLS AND SEEDING MACHINES. — *Canada :* 194569 Maize sower.

Switzerland : 84192 Potato planter.

United States : 1321226-1322574-1322915 Potato planters ; 1322709 Machine for cutting seed potatoes ; 1324045 Maize and pea sower ; 1324618 Machine for replanting ; 1324728 Accessory for sower.

VARIOUS CULTURAL OPERATIONS. — *Canada :* 195151 Maize cultivator.

New Zealand : 40911 Weed extirpator.

Switzerland : 84394 Swede hoe ; 84396 Combined hoe and tillage machine.

United States : 1321152 Straw spreader ; 1324187 Cultivator for mangolds, etc.

CONTROL OF DISEASES AND PESTS OF PLANTS. — *Canada :* 194708 Machine for destroying potato bugs ; 194868 Couch-grass destroyer.

France ; 497314 Machine for barking and lime-washing vines and fruit trees.

New Zealand :— 40911 Weed extirpator.

United States :— 1322133 Cotton chopper ; 1322742 Weed extirpator ; 1323016 Machine for destroying the cotton boll weevil (*Anthonomus grandis*).

REAPERS, MOWERS AND OTHER HARVESTING MACHINES. — *Canada :* — 194807 Hay rake ; 195173 Bean, etc., harvester ; 195218 Machine for supporting hay to be tedded ; 195281-195573 Shocking machines.

Switzerland : — 84193 Device for protecting the mower knife-bar ; 84194 Machine for compressing and tying sheaves.

United Kingdom : — 134442 Mower.

United States : — 1321805 Sorghum header ; 1321977 Machine for treating binder thread ; 1323388 Mower ; 1323404 Tobacco harvester ; 1324031 Shocking machine ; 1324683 Maize harvester.

MACHINE FOR LIFTING ROOT CROPS. — *Canada :* — 194751 Potato lifter ; 195475 Potato gatherer.

United States :— 1321326 Groundnut harvester.

THRESHING MACHINES. — *Canada :* — 194263 Threshing machine ; 194900-195000-195104 Sorters.

United States :— 1321263-1321510-132877 Sorters ; 1321979 Combined harvester and thresher ; 1322303 Maize thresher ; 1323691 Seed-cleaning machine ; 1323784 Seed cleaner and sorter ; 1323906 Paddy thresher.

TRANSPORT. STORAGE AND PREPARATION OF CROPS. — *Canada.* — 193935 Hay press ; 194318 Fruit sorter ; 195261 Silo door ; 195452 Sectional silo.

Switzerland : — 84195 Process and machine for drying damp crops, especially maize cobs.

United States :— 1321263 Hay press ; 1321851 Potato sorter ; 1321991 Hay stacker for barns ; 1322256 Device for drying hay.

FORESTRY. — *Canada :* — 195098 Stump destroyer.

France : — 498202 Machine for felling coppice wood.

Switzerland :— 84395 Machine for tying wood in bundles.

TRACTION AND STEERING OF AGRICULTURAL MACHINERY. — *Canada :* — 194784 Attachment between a tractor and an agricultural machine ; 194869 Tractor draw-bar and hook ; 195009 Garden tractor ; 195228 Traction mechanism for ploughs.

France :— 498185 Machine for propelling and drawing agricultural machines.

New Zealand :— 40807 Farm tractor.

Switzerland :— 84389 Device for converting an automobile into a tractor ; 84390 Bearing wheel for tillage machines.

United States : — 1321415 Wind engine.

FEEDING OF LIVESTOCK. — *Switzerland :*— 84006 Root chopper ; 84393 Root and tuber cutter.

United States :— 1324147 Straw chopper.

POULTRY FARMING. — *Canada :*— 194184 Machine for applying insecticides to poultry.

United Kingdom :— 134492 Poultry food.

INDUSTRIES DEPENDING ON PLANT PRODUCTS. — *Switzerland :*— 84196 Steam drier for fruit, etc.

DAIRYING. — *Canada :*— 193903 Milking machine ; 193904-193905-193956-194127 Milking-machine teat cups ; 195589 Churn.

New Zealand :— 42068 Milking machine.

United States :— 1321372-1322588-1322589 Milking machine pulsators.

VARIOUS. — *New Zealand :*— 41649 Wire fence with reinforced concrete posts ; 42302 Device for preventing stock from breaking metal fences.

United States : — 1322024 Apparatus for heating the water in a tank ; 1323771 Wire stretcher.

AGRICULTURAL INDUSTRIES.

INDUSTRIES DEPENDING ON PLANT PRODUCTS

458 - **Competition for Wines from Direct Bearers.** — DEGRULLY, L., in *Le Progrès agricole et viticole*, Year XXXVII, No. 6, p. 131. Montpellier, February 8, 1920.

Although the vineyards in the south of France were almost free from mildew during the summers of 1918 and 1919, thanks to the persistent drought, many vine-growers continue to turn to direct bearers as they know that these favourable conditions are only temporary and may be followed by less kindly years, so that they consider the *partial* adoption of direct bearers as a sort of insurance against bad luck. It was on account of this, that the " Société centrale d'Agriculture " of Gard organised, at the end of January, 1920, a competition for wines produced by direct bearers in that department.

The tasting jury, with M. TOUCHARD VERDIER presiding, collected its remarks in a report from which the author has taken the following notes : —

157 Gaillard-Girerd, good wine with a rather special taste.

Baco 22 A, good wine slightly foxy ; the same, gathered in 1918 was much improved.

880 Seibel, foxy.

2007, a good wine, a little foxy.
128, good blending wine, highly coloured.
1025, ordinary wine, passable.
1000, mediocre, not worth encouraging.
2006, very good, slightly foxy.
1028, very ordinary.
Couderc, 7120, good average wine.

Tasting competitions like this are very useful in enabling the interested persons to form an opinion of a variety before committing themselves to large plantations and thus risking a loss.

459 – **Role of Bean Flower in Bread-Making.** — KAYSER, ED., and ARPIN, in the *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. VI, No. 7, pp. 144-150. Paris, February 18, 1920.

It has been long known that bakers, in order to improve the quality of their dough, like to mix the flour with bean flour, in a proportion that never exceeds 4 % ; though without knowing the scientific explanation of this old custom.

M. FLEURENT, who found in 1899 that the gluten in a flour should contain 1/4 of gluten and 3/4 of gliadin in order to make the best bread, has shown that bean flour contains, on the contrary, a large excess of glutenin, which again balances the two constituents of the gluten, when they are not present in the right proportions.

The authors have attempted to find out why bean flour has this good influence in bread-making. They found that as sucrose and the proteolytic diastases were not very abundant in bean flour, the improving effect of bean flour on wheat flour could be probably explained as follows : —

1) Bean flour contains a considerable proportion of amylase, as the authors found by its action on macerated malt.

2) Thanks to its content of soluble nitrogenous matter, it assists alcoholic fermentation, increases the proportion of sugar transformed, the weight of yeast and the quantity of carbonic acid given off ; in this connection, the strain of the yeast seems to be as important as the origin and composition of the bean and wheat flours (which varies with the rate of bolting) used.

3) It helps lactic fermentation, the lactic ferments produce a certain quantity of carbonic acid and, at the same time, lactic acid which, in moderates amount, assists the transformation of the assimilable nitrogenous matter and protects the mass against butyric fermentation.

4) The principles contained in bean flour may possibly have a stimulating effect on the secretion of the alcoholic zymase by the yeast for not only does adding them cause the fermentation to start more rapidly, but adding them plus a few decigrams of wine yeast, in the presence of 40-45 % of sugar, gives rise to a quicker evolution of gas as well as a thicker froth than that observed in a tube to which no bean flour had been added, which shows a very active zymase.

5) As M. FLEURENT ahs shown, glutenin corrects the excess of gliadin in wheat flour ; the addition of bean flour, which brings in glutenin, is

all the more necessary in making bread from flour poor in glutenin seeing that a part of this, according to KOSUTANY, is changed to gliadin and that it is essential to maintain a suitable proportion between these two elements.

This work also shows that as baking flour varies in composition, bean flour should be used judiciously and only added to wheat flour in a suitable proportion. Again, as the composition of bean flour is variable, their qualities should be determined by analysis.

460 – **Manufacture of Vegetable Oils in Japan.** — *Bulletin des Matières Grasses de l'Institut Colonial de Marseilles*, 1919, No. 5, p. 216. Paris, 1919.

The oil works in Kobe and district that treat copra and soya have done remarkably well owing to the greatly increased demand for vegetable oils in the United States during 1917 and 1918. The total Japanese production of oil is 223 500 cases (7894 metric tons) a month, consisting of :— Soya, 92 500 cases; coconut, 68 000; rape, 44 000; cotton, 16 000 ; groundnut, 3 000 cases. In the consular district of Kobe there are 25 large vegetable oil-mills which produce roughly 75 % of the whole Japanese output. All except 3 press out the oil, the remaining 3 use benzine for extraction purposes. Three types of mill are in general use : — 1) the round type with a base about 46 cm. across, used for soya and rape ; 2) the type with an oblong, flat base, measuring some 75 × 35 cm., used for copra; 3) the bowl type, in which a stone roller crushes a certain amount of seed pulp kept in by iron circles, used to crush soya and groundnuts a second and third time.

The Kashiwara oil works employs the latest American system of rotating screw press. When filtering is required, ordinary filter presses with fullers' earth are employed. A new mill with a capacity of about 20 000 cases a month is being built, and many local mills are being enlarged so as to increase their output or to enable them to treat other seeds. The plant installed is usually an adaption of American or Japanese machines for treating cotton seed.

461 – **Studies on the Rustiness of Sheet Rubber.** — HELLENDOORN, H. J., in the *Archief voor de Rubbercultuur in Nederlandsch-Indië*, Year III, No. 9, pp. 419-436. Batavia, October, 1919.

The rustiness of sheet rubber (1) has been attributed to various causes ; it has been ascribed to the formation of a superficial layer of resin ; MORGAN suggested that it was due to incomplete coagulation of the latex and EATON

(1) Sheet rubber is prepared as follows : — The latex is coagulated in enamelled dishes like those used in photography; the coagulum is taken out and squeezed with a wooden roller on a wooden table to remove the water; the sheet thus obtained is rolled between rollers with different patterns on their surface and turning at the same speed (in making crepe rubber, they are closer together and run at different speeds) the distance between the rollers is decreased each time the sheet is passed through, so that the sheet becomes thinner and marked with regular figures ; in this way the diamond sheets are obtained ; they are then dried and smoked (crepe is not smoked). (*Ed.*)

thinks that it is a deposit of certain constituents of the serum, especial proteins, dried in a film on the surface of the rubber.

The author's researches have led him to the conclusion that rustiness is due to the decomposition of the serum, especially of the protein matter, by an aerobic micro-organism. The results of the experiments are given below :—

1) *Experimental production of rustiness.* — The author was always able to produce rust experimentally on sheets just taken from the roller and kept in a damp atmosphere for 24 or 48 hours. These sheets were hung up in petrol tins containing a layer of water on the bottom and tightly closed ; small pieces of rubber placed in a glass containing water on the bottom also became rusty.

The great importance of the dampness of the atmosphere in which the sheet is placed after rolling is shown by the fact that sheets placed in a dry room at 40-60° C. immediately after rolling never became rusty, while, at the ordinary temperature, rust occasionally appeared during damp weather. When the petrol tin mentioned above was not hermetically closed, the parts of the sheets turned towards the top and near the cover where there was some ventilation were sometimes free from rust, whereas the lower parts and those near the water in the bottom were always rusted.

2) *Rust occurs if the coagulum is only rolled into sheets some time after coagulation.* — Arens has stated that when the coagulum is left in the coagulation dishes for some time after it is done (a night, for example), the part of the sheet corresponding to the upper side of the coagulum and which has, consequently, been exposed to the air, is more rusty than the part of the sheet corresponding to the lower part of the coagulum that was immersed in the serum. This is due to the fact that infection and, possibly, the development of the aerobic organism, can take place more quickly on the surface. The author found that the rust increased if the sheets were rolled 24 hours after coagulation instead of immediately after.

It should be noted that the atmospheric conditions in which the sheet is placed are very important, as pointed out previously, and they may act in both ways on the effect of the infection on the coagulum. Thus, it may happen that the lower side of the sheet in the tin is more rusty than the other side on account of the greater humidity to which it is exposed, even if it was the side that was immersed in the serum during coagulation. In present practice, as the coagulum is rolled immediately after coagulation, rust can only appear on those parts of the sheets that remain damp during the period just after rolling.

3) *Disinfection.* — Rust can be avoided by disinfecting the surface of the sheets as they come from the rollers, e. g., by immersing them for a certain time in dilute solutions of formalin, chinosol (ortho-hydroxyquinoline sulphate), or bisulphite. Even when a large proportion of the untreated sheets is rusty, the disinfected sheets do not show a trace of it, or if the disinfection is not sufficient, they only show traces.

If feebly disinfected sheets are kept for a long time in a damp atmosphere, rust will always appear, but if the sheets are disinfected by placing

in a tin containing dilute formalin instead of water, rust formation is prevented. The same disinfecting effect can be obtained by submitting the freshly rolled sheets to the action of steam or dipping them in hot water. This is the well-known method much used of late years to avoid rusting and surface oxidation due to enzymes. The author found a very slight rustiness on sheets that had been immersed for 10 minutes in water at 35-50° C., and disinfection was complete when the water was at least at 60° C.

4) *Rust caused by an infection.* — The author died before he was able to isolate the micro-organism of the infection, but his experiments demonstrated its existence. If rust from infected sheets is suspended in water, and this water is sprinkled on sheets that have been disinfected by steam, the latter sheets will rust. Similarly very dry sheets infected by a drop of the suspension and placed in a damp atmosphere for some time also becomes rusty.

5) *The micro-organism is acrobic* — Like practical experience, the author's experiments show that air is absolutely necessary for the development of rust on the sheets. Thus if a newly made sheet is rolled up tightly, only the outer part in contact with the air will rust if it is placed in a damp atmosphere. Again, if sheets hung up side by side become rusty, it has been demonstrated by practical experience that sheets that are touching remain free from rust. The author has shown by special experiments that rust does not grow in an atmosphere deprived of oxygen.

6) *Effect of temperature.* — The optimum temperature for the organism seems to be about 40° C. When the tins or glasses that constituted the damp atmosphere were placed in an incubator at 40°, rust developed with greater intensity than at the room temperature (27° C.); but at 50° C. no rust appeared. This temperature is perhaps too great for the growth of the micro-organism, but it may be that at 50° C. the humidity of the surrounding air is too low, so that the organism cannot obtain sufficient moisture.

7) *Source of food material.* — The thin layer of serum material that remains on the sheet after draining, or the substances absorbed by the rubber, constitute the sources of the food material for the micro-organisms. In this respect, diluted serum seems preferable to non-diluted serum; sheets made from dilute latex (15 % and even 5.7 % of rubber) were more rusted than sheets from an undiluted latex. If a large part of the soluble matter of the serum is left on the sheets when washing them in water after rolling, rusting is not avoided, but, on the contrary, is much more prevalent.

Planters are well aware that if very dilute serum is left on the sheets after washing them in water, there forms a layer with a gelatinous consistency just as if fat had been extracted from the rubber. This substance is probably closely connected with the matter that forms the film of rust. The work, however, was interrupted before this film could be chemically examined.

8) *Disinfection by smoke.* — The question as to whether smoke is a disinfectant that suffices to prevent the growth of the micro-organisms is of great practical importance. If damp sheets are placed in smoking rooms with poor ventilation, a damp atmosphere may be formed with a slightly raised temperature, thus constituting very favourable conditions for the development of the micro-organisms, unless the smoke is a sufficient protection. The author's experiments seem to show that smoke prevents a considerable formation of rust under these conditions, but does not prevent it completely. Rust may develop especially in those places that are not easily penetrated by the smoke, as for example in those parts where the sheets are very close together. But if the sheets are rapidly dried in the air and if they are sufficiently dry when placed in the smoking rooms, smoking is not of great importance in this respect, as the sheets are already under conditions that do not favour the growth of the micro-organism.

9) *Practical method for preventing rust.* — The simplest method for preventing rust under present conditions is to dry the surface of the sheets sufficiently quickly so that the micro-organisms have not time to develop, as they only grow on the surface exposed to the air and require moisture. After rolling the sheets and washing them in water, they should be hung up in such a way, as to be well separated one from another in a well-ventilated place, outside the factory, if required, under a shelter or in a shaded spot, which is preferable to some dark corner of the factory. After drying for a few hours only, they should be put in the smoking room. The sheets should not be left to drain outside the smoking room during a night.

Rust can also be prevented by disinfecting the surface of the sheet with a dilute solution of formol or chinosol, but this method is not to be recommended, as it is less efficacious and costs more than the practical method described previously.

The method which consists in plunging the sheets for a certain time into warm water should be discarded, as the quality of the rubber might suffer.

462 – **Utilisation of Frosted Sugar Cane as Fuel, and its Calorific Value.** — PADROS, J. S., in the *Universidad de Tucumán, Informes del Departamento de Investigaciones industriales*, No. 7, pp. 33-43. Buenos Ayres, 1918. — DIAZ, C. *Ibid.*, p. 44.

In June and July, 1918, there were sharp frosts in the Tucumán region of Argentina, which rendered large quantities of sugar cane of no use for sugar manufacture. As the question of utilising them came up, Prof. PADRAS suggested their use as fuel, as 3750 kg. of cane with 70 % of moisture is equal in calorific value to 1000 kg. of fire-wood.

Señor DIAZ has studied the fuel value of frosted canes belonging to some of the varieties grown at Tucumán ; he obtained the following results, calculated on the basis of the dry matter.

Fuel value of certain varieties of sugar cane.

	Java cane 234	Java cane 213	Java cane 228	Java cane 36	Cane charcoal *
Eau	64.75 %	58.67 %	61.00 %	55.00 %	3.5 %
Combustible matter	35.35 %	41.33 %	39.00 %	45.00 %	96.5 %
Fuel value	4140 cal.	4075 cal.	4017 cal.	4009 cal.	6661 cal.

* Incompletely carbonised, containing some 20 % of volatile matter.

INDUSTRIES DEPENDING ON ANIMAL PRODUCTS

463 – **Butterfat Losses in Creameries.** — WASHBURN, R. M., DAHLBERG, A. C., SORENSON J. and MORTENSEN, M. P., in *The University of Minnesota, Agricultural Experiment Station Bulletin* 177, pp. 12. University Farm, St. Paul, September, 1918.

The authors have investigated the differences between the actual and calculated yield due to mechanical loss of fat as well as to losses due to inherent defects of the Babcock test (1), or to faulty manipulation of that test under commercial conditions. The observations were spread over 43 working days at the Minnesota State Creamery.

A preliminary series of studies convinced the authors that the Babcock test for milk and cream, carried out without special precautions, is sufficiently accurate for the purpose. But the method laid down for carrying out this test should be strictly adhered to. Faults committed in the composition of the cream samples, even if they are fresh and not thick, are a source of considerably greater errors than the comparatively unimportant ones due to the Babcock test.

An attempt was made to determine accurately the loss of fat at all the stages of manufacture under ordinary conditions. The weighing vessels, the milk cans, the pasteurisers, the pipettes, pumps, etc., after the usual rinsing, were carefully washed out with boiling water, the water then being weighed and sampled quickly. The water used for washing the butter and the boiling water used for washing the churn were both weighed in the churn and sampled when they were done with. All the washing waters were examined by the Babcock method (bottles of skim milk). The skim milk and the buttermilk were examined by means of the gravimetric method and the Babcock test. Samples of buter were taken at 10 different points of the churn at least and examined gravimetrically. Details of the mechanical losses are given in the appended table see page 513.

The mechanical loss is practically independent of the volume treated, so that the percentage loss in a large creamery is very small, but careless work will considerably increase it.

See *R.* March, 1920, N. 362, (*ld*).

The chief cause of the loss of butter fat that could not be specified, was due to the fact that the Babcock method shows only about one-third

Losses of fat in the mechanical method of butter-making.

Causes of loss	Daily losses of fat at the experimental creamery	
	lb.	*Babcock test*
Weighing vessel, vat, heater	0.38	0,13 %
Cream pre-heater, pasteuriser, refrigerator	1.55	0,23
Vessel for ripening the cream	0.15	0,07
Washing water of the butter	0.14	0,03
Washing water of the churn	0.61	0,14
Total losses in a creamery treating whole milk		1,38
Total losses in a creamery treating cream separated by a hand machine		0,76

of the fat really present in the skim milk and buttermilk, as is shown by the following figures : —

	Babcock method	Gravimetric method
Fat lost in skim milk	0,49 %	1,64 %
Fat lost in buttermiik	0,29	0,9
Fat lost mechanically	0,60	0,60
Fat recovered in the butter	96,72	96,72
Losses that could not be specified	1,90	0,11

The percentage losses of the skim milk and buttermilk are not influenced by the quantity of butter produced each day. In a creamery where whole milk is used, the losses from all causes are 3.17 %, and in a creamery which receives and works cream separated by hand separators, they are 1.4 %, after deducting losses in the skim milk, in the weighing vessel and heater.

The drip method of sampling, which consists in taking samples from a tap in the pipe leading from the heater to the separator, is sufficiently accurate to allow the daily, production to be examined without it being necessary to analyse each day the milk supplied by each client ; the average error of 43 samples taken in this way was 0.39 %.

464 - **Transport of Milk in Frozen Blocks.** — *Le Froid,* Year VII, Vol. VII, No. 12 p. 322. Paris, December, 1919.

The best method for transporting milk for long distances is as follows :— Freeze ⅓ of the volume of the milk in blocks weighing from 10 to

25 kg. ; place one of these blocks in each milk can, then fill with pasteurised milk cooled at 4° C. Milk treated in this way can be kept safely for 2 or 3 weeks and be transported to any distance.

It should not be forgotten however, that while cold reduces the growing power of microbes, it dœs not completely destroy their faculty of secreting specific enzymes, and this, from the hygienic point of view, cold can only be counted upon for preserving sound milk.

PLANT DISEASES

DISEASES NOT DUE TO PARASITES OR OF UNKNOWN ORIGIN.

RESISTANT PLANTS.

465 – **Varieties of Potato Resistant to Wart Disease (*Chrysophlyctis endobiotica*) in England.** — See No. 420 of this *Review*.

MEANS OF PREVENTION AND CONTROL

466 – **Lime-Sulphur Wash or Polysulphides of Calcium as Fungicides.** — See No. 478 of this *Review*.

467 – **Copper Carbonate as a Substitute for Copper Sulphate in the Control of Wheat Smut.** — See No. 469 of this *Review*.

DISEASES OF VARIOUS CROPS

468 – **Experiments on Wheat Smut (*Tilletia Tritici*).** — STRAMPELLI, N., in the *Rendiconti delle sedute della Reale Accademia dei Linei*, Classe di Scienze fisiche, matematiche e naturali, 2nd Half-Year, 1919, Vol. XXVIII, Parts 3-4, pp. 151-153. Rome, 1919.

The author found, in 1918, that "Apulia" wheat, grown over an area of some 7 hectares, was completely free from smut (*Tilletia Tritici* = *T. Caries*), while the other varieties grown near by, especially the "Luigia Strampelli" variety, were fairly severely attacked. In consequence, he has attempted to find whether this difference in behaviour was due to chance or if there was a difference in the susceptibility of these different varieties of wheat to the parasite.

Accordingly, he experimented with the following varieties :— Bianchetta, Cervara, Luigia Strampelli, Gregorio Mendel, Baionette Strampelli, Hizakiri, Gentil rosso, Inversable Vilmorin (beardless soft wheats), Maiorca, Carlotta Strampelli, Rieti, Apulia, Akakomughi (bearded soft wheats), Duro di Puglia and Dauno (hard wheats).

Each variety was sown in a large earthenware pot; in the soil of each pot 20 equidistant holes about 3 cm. deep were made. The holes were powdered abundantly with smut spores, and then the caryopses of the variety of wheat corresponding to the number of the pot were placed in each hole, so that, on germinating, the caryopses were in immediate contact with the spores of the fungus.

The following percentages were obtained for each variety when mature : —

The Bianchetta variety gave	26.30	%	healthy	plants	and	25.50	%	healthy	caryopses
» Cervaro variety gave	10.60	»	»	»	»	5.22	»	»	»
» Luigia Strampelli variety gave	0	»	»	»	»	1.03	»	»	»
» Gregorio Mendel variety gave	45.00	»	»	»	»	40.70	»	»	»
» Baiouette Strampelli variety gave	20.00	»	»	»	»	12.60	»	»	»
» Hizakiri variety gave	5.00	»	»	»	»	10.97	»	»	»
» Gentil rosso variety gave	10.50	»	»	»	»	10.80	»	»	»
» Inversable Vilmor. variety gave	15.00	»	»	»	»	18.30	»	»	»
» Maiorca variety gave	10.00	»	»	»	»	10.15	»	»	»
» Carlotta Strampelli variety gave	42.10	»	»	»	»	36.20	»	»	»
» Rieti variety gave	10.60	»	»	»	»	10.20	»	»	»
» Apulia variety gave	43.75	»	»	»	»	41.26	»	»	»
» Akakomughi variety gave	13.60	»	»	»	»	5.55	»	»	»
» Duro di Puglia variety gave	15.00	»	»	»	»	13.90	»	»	»
» Dauno variety gave	0	»	»	»	»	0	»	»	»

These figures show that the different varieties are attacked with varying intensity by the parasite ; thus a scale based on these figures and on the resistance of the varieties tested would be as follows :—

1) Gregorio Mendel (45.00 % of healthy plants)
2) Apulia (43.75 » » » »
3) Carlotta Strampelli (42.10 » » » »
4) Bianchetta (26.30 » » » »

6) Inversable Vilmorin, Duro di Puglia.
7) Akakomughi.
8) Cervaro, Rieti, Maiorca, Gentil rosso.
9) Hizakiri.
10) Dauno and Luigia Strampelli.

The question as to whether the position of the spores in the soil in respect to that of the caryopses has an influence on the possibility of attack by the parasite was also investigated by the author. For this experiment, Luigia Strampelli wheat was chosen and sown in three pots in the following manner :—

1) In the first pot, 20 caryopses were evenly distributed and covered with a layer of 3 cm. of soil on the surface of which large quantities of smut spores were strewn.

2) In the second pot, two-thirds full of soil, smut spores were strewn until the surface of the soil was black, then a layer of soil 6 cm. thick was placed on top ; 20 wheat caryopses were placed on this and covered with 3 cm. of soil.

3) The third pot was half-filled with earth and smut spores were strewn on it as in the second pot ; a second layer of earth 14 cm. thick was then added, 20 caryopses were sown in it and covered with 3 cm. of soil.

The pot with Luigia Strampelli wheat sown in infected holes as described above was taken as a control.

At maturity, the following percentages were found :—

1) Infection on the soil surface after sowing and covering the seeds with 3 cm. of soil.	Healthy plants	90 % ;	healthy caryopses	82.20 %
2) Infection in the soil under a layer 6 cm. below the caryopses.	»	» 100 % ;	»	» 100,00 %
3) Infection in the soil under a layer 14 cm. below the caryopsis.	»	» 100 % ;	«	» 100,00 %
4) Control pot; caryopses sown in infected holes.	»	» 09 % ;	»	» 1.03 %

While infection was complete when the caryopses was sown in contact with the spores, the percentage of healthy plants at once rose to 90 % when a 3 cm. layer of soil was placed between the caryopses and the spores (case 1 above). The 10 % of smutted plants was certainly due to the fact that spores had been carried by watering from the surface of the soil to the caryopses. There was no infection at all in the other cases.

This shows that, for smut to attack the young plants the spores must be in actual contact with the germinating seeds. Consequently, besides burning the stubble and treating the seed with copper sulphate, the soil should be prepared for wheat by ploughing fairly deeply so as to remove the spores spread on the ground by the wheat as far as possible from the seed. In addition, varieties of wheat should be chosen that are the least sensitive to the parasite.

469 – **Dry Treatment with Copper Carbonate for the Prevention of Wheat Smut.** — Darnell--Smith, G. P. and Ross, H., in *The Agricultural Gazette of New South Wales*, Vol. XXX, Part 10, pp. 685-692, 7 Figs. Sydney, 1919.

Years ago, laboratory and field experiments have led the authors to the conclusion that the copper sulphate solution in which wheat seeds are immersed in order to prevent smut from appearing is clearly injurious, not only to grains that are split or otherwise damaged, but also to healthy seeds, by retarding and, in certain cases even, preventing germination.

After the seed had been treated with the copper sulphate solution, the advice used to be given to immerse it again in lime water made from freshly burnt lime, so as to neutralise the acidity of the copper sulphate. As regards this, the authors think that, apart from the corrosive action of the copper sulphate, simply immersing the wheat in water is more or less harmful to the future plant. For example, if a bushel of wheat is immersed in water for 3 minutes, it requires 8-12 hours to dry. During this period, partial germination takes place and, if the grain is not sown at once in damp ground so that germination may continue, the swollen grains are stopped germinating and, when a second germination takes place some weeks later, when the conditions are again favourable, growth cannot be as healthy and vigorous as if the grains had not begun to germinate once before.

With the object of eliminating the use of water, and of finding a less harmful fungicide than copper sulphate, the authors have carried out

many experiments of recent years and have been led to prefer copper carbonate to all the different dusting powders or gases that had been tried. Copper carbonate, besides being a perfect fungicide, is innocuous to the seed and has the advantage that it can be used in the dry state.

The method finally adopted for treating wheat seeds consists in powdering the seed with dry copper carbonate in the proportion of 2 per 1000. It was found to be essential to cover the seed completely with the copper carbonate powder, which can be better done by using a machine that mixes the wheat and copper carbonate together intimately than by doing it by hand.

The results of cultural tests made in 1917 and 1918 at the Wagga and Cowra Experimental Farms (New South Wales) showed an actual, marked increase in the yield per acre in the cases where the new copper carbonate treatment substituted the old method using a bath of copper sulphate. This increase is positive and, in certain cases, amounts to 100 %.

The advantages derived from the use of copper carbonate instead of copper sulphate can be summarised as follows:—

1) No water is used.

2) There is no injurious action on either seed or young plant such as occurs with copper sulphate.

3) Seed wheat can even be treated several weeks before sowing.

4) No harm comes to the seed if it remains on a dry soil for several weeks without germinating.

5) Better germination is obtained.

6) This method is quicker and less laborious than using copper sulphate solution.

7) A better product is obtained.

8) The total quantity of seed grain required for sowing can be treated when the farmer can best spare the time and not necessarily a day or two before sowing.

470 – **Preliminary Observations on the "Straw-Blight" of Wheat, Oats and Barley in the State of Washington.** — DANA, B. F., in *Science*, New Series, Vol. L., No. 1299 pp. 484-485. Lancaster, Pa., November 21, 1919.

On several occasions during 1918, diseased wheat plants were sent from Olympia and other localities of the western part of the State of Washington to the Agricultural Experiment Station of Pullman for investigation.

Amongst the first specimens received, there were some which, at the base, had elliptical lesions that penetrated through the leaf sheath to the surface of the straw. Plants with these lesions and others with a general blackening of the lower nodes had dead roots from the first node, and the plants had tried to remedy this by giving off roots near to the second node. In certain plants, two rows of roots had been successively killed and still other roots had been given off near the third node. The plants seemed to be of retarded growth and were yellowish in colour.

Further information obtained, particularly from the county of Cowlitz, showed that the disease was the cause of a good deal of lodging, the

stems breaking almost at soil level. From information supplied, the disease had nothing to do with the nature of the soil or the tillage system adopted. It was also observed on oats and barley, but to a slighter degree, with the general blackening of the base of the straw and the death of the roots.

The disease was reported on wheat in the counties of Cowlitz, Snohomish and Thurston; it was most serious in the county of Thurston while, in the county of Cowlitz, it attacked wheat approaching maturity most severely. It was recorded on barley in Pierce county only, and on oats in Clarke, Pierce and Snohomish counties. The wheat harvest in certain localities of Cowlitz and Thurston counties suffered considerable loss, but no data is available to show that the disease had attacked the other cereals equally seriously.

In 1912, CORDLEY published some notes on a straw-blight of cereals in Oregon, but he only described the disease briefly and did not identify the pathogenic agent. The disease mentioned in this case is certainly the same as that which appeared in 1918 in the western part of the State of Washington. Other signs of the disease in the United States have not been recorded. This disease has either been recently introduced into the United States or has so far escaped notice.

The fungus found in the lesions of the straw was examined microscopically with great care in order to identify it. The mycelium was sterile, dark brown in colour, constricted at the points of origin of the lateral branches, and corresponded fairly well to *Rhizoctonia Solani* Kühn, except in the diameter of the hyphae. In the case of plants showing very marked blackening at the base of the stem, the discoloration was found to be due to a very dense, superficial development of dark-brown hyphae, from which, in certain cases, a sclerotium was beginning to form.

So far, no fungoid fructification has been found with the sterile material at the base of the stem.

However, there seems to be a close similarity between the straw-blight observed in the State of Washington and the straw-blight of wheat and other cereals caused by *Ophiobolus graminis* Sacc. This and other fungi related to straw-blight, produce an ascophorous form on the old straw; it seems probable that it must be ascertained whether the fungus causing straw-blight of cereals in the west of the State of Washington also possesses a perfect or ascophorous form which hibernates on the stems of the diseased gramineae. It is also possible that the disease exists on the native grasses, and it is known that, by means of the wild host-plants, other fungi that cause straw-blight can be introduced into the crop rotation. Up to the present, it has not been possible to make a careful study in the field with the object of discovering the ascophorus stage. In the limited work carried out, the only perithecial form found on old wheat stubble was a species of *Pleospora*, and it cannot yet be said whether the disease in question is the same as one of the similar diseases that have been studied in Europe or Australia.

Reports show that the disease is fairly widely diffused in the western part of the State of Washington and the notes furnished by CORDLEY seem to show that the disease may have already manifested itself for some years. Only with time can it be ascertained if the disease will attain, in the United States, the same gravity as the pathological manifestations groupe dunder the name of straw-blight of cereals in Europe and Australia.

471 – **On the Silver Leaf Disease in England** (1). — BINTNER, J., in the *Royal Botanic Gardens, Kew, Bulletin of Miscellaneous Information*, Nos. 6-7, pp. 241-263, 8 Figs., 1 Pl. London, 1919.

The author's researches lead to the conclusion that there are two types of silver leaf disease, 1) the *true silver leaf*, which is the more common and is caused by the basidiomycete *Stereum purpureum*, and 2) the *false silver leaf*, which is comparatively rare and is apparently due to a physiological weakening of the plant. It is difficult to distinguish between the two forms by external examination as the foliage has practically the same appearance in both cases. *True silver leaf*, however, is characterised by a dark coloration of the wood when seen in cross section, and by the ease with which the upper epidermis of the leaves peels off.

The chief characteristics of *true silver leaf* are as follows :— The normal green colour is obliterated by the presence of air spaces under the cuticle, owing to which the light is reflected and the leaf takes on a silvery appearance. As a rule, there is no reduction in the number of the chloroplasts. As a result of the dissolution of the median lamella of the cell walls of the leaf, the leaf tissues easily fall apart when a section is cut through them. The dissolution of the median lamella is possibly caused by the production of some diffusible toxic substance during the metabolism of the fungus and the invaded cells of the host ; this substance is then conveyed to the leaves by the water ducts where it causes a change in the enzymes which can dissolve the pectic substances of the cell wall. Moreover, infected plants nearly always show continuous dark-brown streaks in the woody tissues of the stem, twigs, branches or roots which, when examined under the microscope, show the presence of extremely fine filaments of *S. purpureum*. If branches suffering from silver leaf are kept in water for 48 hours, they change the colour of the water to a degree of intensity varying with the severity of the attack.

Initial infection takes place just above the soil level, and even immediately below it and, from the information available, the fungus can only penetrate the host by means of open wounds. Recent inoculation experiments confirm the opinion that wounded superficial roots can be infected ; the frequency of the infection probably depends on the variety of stock used for grafting. When the disease is limited to one of the large branches the disease is caused by a local infection and has not yet spread to the main stem. Diseased suckers originating from a healthy tree show that the disease is present in the roots, while the appearance of healthy shoots on diseased plants indicates crown or stem infection that has

(1) See *R.*, August, 1917, No. 775. (*Ed.*)

not yet reached he root system. The author has examined the following plants all of which are subject to *true silver leaf*:— Victoria plum (and the stocks on which this variety is usually grafted, viz., the Brompton plum and Common plum), *Prunus lusitanica*, *P. triloba* var. *flore pleno* amongst apples, the Lord Grosvenor and Bramley's Seedling varieties; *Spiraea japonica* var. *glabrata*. *Neviusia alabamensis*, *Ribes cereum*, *Laburnum alpinium* and *L. vulgare*. Although fructifications of *Stereum purpureum* have not yet been noticed on *Spiraea japonica* var. *glabrata* and *Ribes cereum*, it is certain that the hyphae observed in the tissues of these plants were identical with those of the fungus obtained in artificial cultures.

On account of the frequency and disastrous effects of *true silver leaf* and the ever increasing world-wide importance of the disease, the author particularly recommends the destruction of *S. purpureum* wherever it occurs, whether as parasite or saprophyte.

If the disease is found localised in the upper set branches of a tree, the diseased branches should be cut off below the point where the disease has changed the colour of the wood. If the lower branches are attacked, there is little hope of their recovery because, in this case, the fungus has already invaded the main stem; all that remains to be done is to uproot the tree before the fructifications of the fungus can develop (usually about September).

If a branch is amputated, the stump should be cut as close as possible to the main stem or at its point of origin if it is a secondary branch, the object being to help the callus to form as rapidly as possible. When pruning branches, the cut surface should be at once protected with Stockholm tar or grafting wax to prevent spores of the fungus from penetrating.

All dead or diseased wood should be removed from the plantation, for the fungus in wood quickly develops fructifications whose spores are dangerous to the surrounding trees.

Diseased branches should not be used for fencing as they would be just as dangerous as if they were left in heaps in the orchard. The wood must be stored in very dry places to prevent the growth of the fungus. In large plantations the cut branches should be made into charcoal on the spot.

In plantations where the plough is used for catch crops, it is difficult to avoid damaging the surface roots, but the additional injury due to the use of the spade can be minimised by using it carefully and by the pulling up of suckers. Varieties of plums grown on their own roots produce few if any suckers and, consequently, these varieties should be planted whenever circumstances permit. Varieties of plums that resist or are less susceptible to the disease, such as the Yellow Pershore (also known as Yellow Egg plum) and Early Rivers plums should be planted.

Varieties of apple that produce cookers of the soft type are more subject to silver leaf than the others, which, should therefore be planted in preference.

Certain stocks, suchas the Brompton and Common plums, are very susceptible to the disease, whilst the Yellow Pershore has a certain degree of resistance in addition to other good qualities.

Ornamental trees and shrubs known to be suffering from the disease should not be pruned unless the cut surfaces can be protected immediately after pruning.

When infected plum trees are replanted, the use of varieties such as Victoria and Czar that are already known to be subject to *true silver leaf*, should be avoided, and pears, Cob-nuts or Filberts should be planted between the plums.

False silver leaf is much less prevalent than *true silver leaf*, and can easily be identified by certain microscopic characters. The number of chloroplasts in the leaves is reduced, so that the leaves take on a somewhat silver-lead sheen which is visible even at a distance ; the median lamella is not dissolved and the cells are not broken up. No trace of hyphae has been found in any part of the diseased plant. No continuous streaks are seen in which the wood changes colour and cut branches do not affect the colour of water in which they are immersed.

False silver leaf is sometimes found on apple trees (Grenadier and Bramley's Seedling on *Camelia Sasanqua* var., *Koelreuteria paniculata*) and, rarely on cultivated varieties of Cherry, Peach and Plum trees. It appears that trees or shrubs that have suffered from *false silver leaf* for one or two seasons will resume their normal appearance in the following year if they receive improved cultural treatment.

472 – **Diseases of the Avocado-Pear (*Persea gratissima*), in Trinidad.** — Rorer, J. B., in the *Bulletin of the Department of Agriulture, Trinidad and Tobago*, Vol. XVII, Part 3, pp. 132-133, 2 Pl. Port of Spain, 1919.

As there are no true plantations of *Persea gratissima* in Trinidad, the trees being disseminated in cacao or other plantations, the avocado pear has remained free from serious fungoid diseases.

On account of the interest recently shown by the planters in this fruit tree and as large plantations will probably be established in the island and will give rise to an export trade, the author has considered it a suitable moment for attracting attention to the diseases which may attack the tree and become epidemic, as one at least has already become in other regions.

The sole serious disease observed so far on the fruit of *P. gratissima* is that known as anthracnose, caused by a fungus very similar or closely related to that which causes anthracnosis of the mango, i. e., *Gloeosporium Mangiferae* (*Colletotrichum*) *gloeosporioides*). It is almost impossible to buy a fruit in the market that is not more or less attacked by the disease. As the avocado pear is eaten at once, the disease does not cause serious loss, but, if the fruit is packed for export, they will all rot in a few days.

The disease first shows itself on the fruit by the formation of a very small brown spot. If the attack takes place when the fruit is green, the brown area does not spread, a slight depression forms, and cracks appear all

round the edge of the spot ; black pustules may exist in the centre of the tissue that has gone brown. If the attack is serious, the young fruit falls before it is ripe ; otherwise, the fruit may ripen, but the epidermis cracks round the brown spot. When the fungus attacks fruit with a tender skin, it penetrates the pulp and forms a conical mass of diseased tissue which may extend to the stone, and the fruit gradually rots. Ripe fruit when attacked, rots very rapidly. As in the case of the mango, the fungus also attacks the leaves and, up to a certain point, may cause their fall.

To combat the disease, Bordeaux mixture must be continually sprayed on the tree from flowering time until the fruit is ripe. The wetter the weather, the more the number of sprayings that will be required.

If the fruit has to be sent some distance, it is of primary importance that they should first be sprayed. Even when the skin seems perfectly healthy, avocado pears, in practice, are always infected by the fungus which finds the most favourable conditions for growth when the fruit is packed in baskets or boxes.

It is often noticed in Trinidad that young avocado branches die from the tip downwards. Microscopical examination has shown that such branches are infected by *Diplodia cacaoicola*.It has not been shown yet that this fungus can attack unwounded branches, but it probably penetrates the very young tissues through wounds produced by anthracnose, and, once in the branch, grows rapidly towards the main stem of the tree. The same fungus has been recorded on specimens of grafted avocado pears in which it probably enters by wounds caused by grafting. The method of control recommended for anthracnose is also suitable for this disease.

INJURIOUS INSECTS AND OTHER LOWER ANIMALS

473 - ***Thymalus fulgidus*, a Beetle living on *Polyporus betulinus* and *Daedalea confragrosa*, Polyporaceae living respectively on the Birch and Willow, in New Jersey, U. S. A.** — WEISS, H. B., in *Entomological News*, Vol. XXXI, No. 1, pp. 1-13. Lancaster, Pa., January, 1920. GENERA

Thymalus fulgidus Er. has been long known as a coleopteron living on *Polyporus betulinus*, a parasite of the birch. According to various authors, this beetle has been recognised as common on this *Polyporus* in New England, Massachusetts and New Jersey.

During the winter of 1918-19, the larvae of this beetle were very abundant in the fructifications of *P. betulinus* at Morristown, Oradell and Monmouth Junction and in those of *Daedalea confragosa* at Monmouth Junction and High Bridge (New Jersey). These two polyporaceae are common in NewJersey, the former on birch, the latter on dead wood, but chiefly on living willows.

The adult beetles, like the larvae, live on the contexts and tubes of the host fungus and when numerous the fructifications are completely riddled.

MEANS OF PREVENTION AND CONTROL

474 – **Parasites of the Maize Pyralid (*Pyrausta nubilalis*), in France** (1). — VUILLET, A., in the *Bulletin de la Société entomologique de France*, No. 17, pp. 308-309. Paris, 1919.

Fifteen larvae of *Pyrausta nubilalis* Hb, from the south-west of France were reared, and six were found to be parasitised in 1919. Two unidentified hymenoptera emerged from two larvae of the pyralid; from another two caterpillars two specimens were obtained of the tachinid fly *Paraphorocera senilis* Rondani; a fifth gave rise to the tachinid *Lydella stabulans* Mg.; the pupa of a parasitic fly was also obtained but it did not hatch. The two identified species are common and parasitise various larvae.

Different species of birds hunt for the larvae of *Pyrausta* in the stems of maize.

475 – ***Charips* (*Charips*) *leguminosa* n. sp., a Hymenopteron obtained from *Aphis bakeri* in Idaho, U. S. A.** — WELD, L. H., in *Entomological News*, Vol. XXXI, No. 1, pp. 14-16. Lancaster, Pa., January, 1920.

The author describes as new to science, under the name of *Charips* (subgen. *Charips*) *leguminosa*, a cynipid reared from *Aphis bakeri* Cowan (the clover aphis) in June-July, 1919, at Twin Falls, Idaho, by Mr. R. H. SMITH. The latter repeatedly attempted, without success, however, to rear the cynipid as a parasite of the aphid; he twice reared the hymenopteron in cages with *Aphelinus lapsiligni* Howard, the chief parasite of that aphid. For this reason he is inclined to believe that the cynipid is not a primary parasite but a parasite of *Aph. lapsiligni*.

476 – ***Apantales gabrielis* n. sp. a Hymenopterous Parasite of *Pionea forficalis*, a Microlepidopteron Injurious to the Cabbage in France.** — GAUTIER, Cl., and RIEL, PH., in the *Bulletin de la Société entomologique de France*, No. 17, pp. 309-312. Paris, 1919.

Description of a species new to science, under the name of *Apanteles gabrielis*, a braconid parasitic on the larvae of *Pionea forficalis* L. (*Pyralidae*), which, in 1919 (June-July, and September-October), attacked in great numbers a cabbage crop very seriously at Monplaisir, near Lyons. Just under half the larvae of *Pionea* were parasitised by the new braconid.

Contrary to what takes place with most species of *Apanteles*, the larvae of *A. gabrielis* emerge, under natural conditions, from the larvae of *P. forficalis* when these are hardly more than half grown.

477 – **Researches on the Food of Certain Wild Birds in Great Britain.** — COLLINGE, W. E., in *The Journal of the Board of Agriculture*, Vol. XXV, No. 6, pp. 668-691, 7 Figs. No. 12, pp. 1444-1462, 9 Figs. London, September, 1918 - March, 1919.

The author has examined the contents of the stomach and crop of 3670 adult birds and 595 nestlings, embracing 9 wild species. From the results obtained, he concludes that the volumetric method, i. e., the percentage of the total volume represented by each food, is the only reliable method for judging the nature of the food of a bird and its true economic value; that the numerical method is highly misleading and may lead to

(2) See *R.* Oct.-Dec., 1919, No. 1289. (*Ed.*)

wrong conclusions ; that, consequently, all the work done with the help of the latter method on the food of wild birds is of doubtful value, and should be begun again, using the volumetric method.

Of the 9 species examined, the house sparrow (*Passer domesticus*) and the wood pigeon (*Columba palumbus*) are distinctly injurious ; two, the rook (*Corvus frugilegus*) and the sparrow-hawk (*Accipiter nisus*) are too numerous and, consequently injurious ; locally, the missel-thrush (*Turdus viscivorus*) is common ; four, the skylark (*Alauda arvensis*), the green wood pecker (*Gecinus viridis*), the kestrel (*Falco tinnunculus*) and lapwing (*Vanellus vulgaris*) are decidedly useful.

In the interest of agriculture energetic measures should be taken against the house sparrows and wood pigeons and all the orders for the protection of rooks, sparrow-hawks and missel thrushes should be revoked. But no effort should be spared to protect skylarks, green wood peckers, kestrels and lapwings.

In the second article, which continues the previous one, the author gives the results of examining the stomach contents of 798 adult birds and 166 nestlings embracing 8 species of wild birds. It was found that the jackdaw (*Corvus monedula*), the greenfinch (*Emberiza citrinella*), the great tit (*Parus major* subsp. *newtoni*), the blue tit (*Parus caeruleus* subsp. *obscurus*), the thrush (*Turdus musicus*) and (*T. pilaris*) are very beneficial.

The great tit, blue tit and fieldfare are so useful that they ought to be protected.

In spite of the damage it does, it would be a mistake to advocate repressive measures against the chaffinch (*Fringilla coelebs*). The starling (*Sturnus vulgaris*) has been allowed to increase unduly, with the result that it does more harm than good.

Temporary measures of repression against this bird would certainly keep its numbers down to normal limits, with considerable benefit to farmers and fruit-growers.

478 - **On the Mixture consisting of Lime-Sulphur or Polysulphides of Calcium as Insecticide or Fungicide.** — Report of Prof. BRUTTINI. Rome, L'Universelle, Imprimerie polyglotte, 1920, pp. 36 + 6 Figs.

This report deals with the preparation of " an old remedy prepared in a new way ". In fact, instead of making lime-sulphur mixture (1) with definite proportions of lime and sulphur which are treated with boiling water, the author, according to his patented process, produces polysulphides of calcium in a super-concentrated mixture at 35°-40° Baume, by using, instead of commercial sulphur, that produced by purifying lighting gas in a special way. This constitutes a new use for this residual sulphur, which is now being produced at the gas-works in Rome belonging to the " Società Anglo-Romana ", where a special plant designed for continuous running has been installed.

The method of preparation is not given, but a description of the product, which is sold under the name of " Supersolfo ", is given. Its charac-

(1) See *R.*, May, 1918, No. 613 and *R.*, July, 1918, No. 826. (*Ed.*)

teristics are as follows : Density from 35°-40° B. ; absence of residue ; very intense chestnut-red colour which turns to red when it is diluted with water ; characteristic strong smell ; great resistance to the action of the air, i. e., there is not a continuous formation of insoluble crystals of calcium sulphite, as is the case with the mixture made from commercial sulphur ; and, finally, a fair content of iron in the soluble state, not combined with cyanogen. This characteristic is very important, for the vigorous action of polysulphides when sprayed on plants, due to the sulphur, is, in this case, certainly increased by the action of the iron.

The author describes the serious damage caused by parasites to cultivated plants and, basing his calculation on figures published before the war (2) but trebled or quadrupled in order to bring them into line with present prices, estimates that agriculture in civilised countries loses the enormous amount of 10-20 milliard francs owing to this cause.

In the chapter on the history of the lime-sulphur mixture, the author quotes numerous results of experiments in different countries, all agreeing on the efficacity of this remedy, and gives a list of 34 American works that make polysulphides of calcium for agricultural use. Though this list is not complete, ii shows what a large use is made of this insecticide and fungicide by American horticulturists.

The chemical composition of the mixture — which is very complex — is still uncertain, but it can be assumed that it is a solution of calcium tetrasulphide and pentasulphide with small quantities of hyposulphite. Polysulphides, being very easily oxidised, decompose in the presence of air, giving, in the order of formation : 1) tetra or pentasulphide of calcium ; 2) hyposulphite of calcium and sulphur ; 3) calcium sulphite and sulphur ; 4) calcium sulphate.

The same changes take place on the leaves, on which sulphur is deposited in a much finer state than ground sulphur, owing to which it is more active. Various opinions have been advanced to explain the action of polysulphides on parasites of plants ; some attribute it to the action of sulphur vapour, and some to the oxidation of the sulphur with the production of sulphur dioxide. The production of sulphuretted hydrogen by the action of the carbon dioxide of the air should also be considered. In addition, polysulphides rapidly extract the oxygen from insects, thus disorganising their tissues and even asphyxiating them.

In diluting " Supersolfo ", the author starts with the basal mixture (at 21-24° B.) and suggests its use at 8 to 10 % strength for spraying in winter and at 5 to 6 % for that in spring and summer. As the density is 35-40° B., the amount of mixture per 100 litres of water is from 2.90 to 4 litres for winter use and 1.80 to 2 litres for spring and summer use.

A list is given of the chief scales, injurious insects and fungi that can be successfully treated with polysulphides : *Tetranychus telarius ; T. mytilas-*

(2) Cf. Louis-Dop : *Rapport sur la coopération internationale dans la lutte contre les maladies des plantes.* International Phytopathological Conference (Rome, Feb. 24, 1914). International Institute of Agriculture, Rome, 1914). (*Ed.*)

pidis ; " bianca-rossa " of *Citrus* spp., *Chrysomphalus dictyospermi ;* fig scale, *Ceroplastes rusci ;* peach scale, *Lecanium persicae ;* black olive scale, *Saissetia oleae ;* apple aphis, *Schizoneura lanigera ; Hyponomeuta malinellus* on apple ; apple pyralid, *Carpocapsa pomonella ;* peach-leaf curl, *Exoascus deformans ;* plum pockets, *Exoascus pruni ;* loose smut of wheat, *Ustilago tritici ;* wheat smut, *Tilletia tritici* ; powdery mildew of peach and rose, *Oidium leucoconium* (*Sphaerotheca pannosa*) ; brown rot of fruit, *Monilia fructigena* (*Sclerotinia fructigena*) ; " occhio di pavone " of olive, *Cycloconium oleaginum ;* powdery mildew of grape, *Oidium Tuckeri ;* apple and pear scab (*Fusicladium dendriticum* and *F. pirinum*), etc.

A special note is given on the powdery mildew of the grape (*Oidium Tuckeri*), against which polysulphides were successfully tried some years ago ; the experiments are being taken up again. The author quotes, in respect of this, the favourable opinions expressed by PEYRON, D' OTTAVI and the more recent ones of SAVASTANO in Italy and CAPUS in France, and it recommends that a large use should be made of polysulphides against this parasite of the vine, especially as polysulphides are much cheaper than powdered sulphur.

The author also draws attention to the effect of polysulphides on mites and insects that live on domestic animals.

The report concludes with a list of 64 works on the subject.

479 - **The Almond Scale (*Eulecanium coryli*) in Italy.** — SILVESTRI, F., in the *Bollettino del Laboratorio di Zoologia generale ed agraria della R. Scuola superiore d'Agricoltura in Portici*, Vol. XIII, pp. 127-192 + 34 Figs. Portici, 1919.

INSECTS, ETC INJURIOUS TO VARIOUS CROPS

Morphological and biological description of *Eulecanium coryli* L., found by the author on the following plants : — hazel, pear, apple, plum (wild and cultivated), maple, elm, hawthorn, azerole-tree, golden willow and hornbeam. It has also been recorded by various authors on many other plants as well as these.

E. coryli is known in Sweden, Denmark, England, Holland, France, Germany, Bohemia and Italy, and it has apparently been introduced into North America. In Italy the author has found it in the provinces of Macerata, Perugia, Campobasso, Avellino, Caserta, and Naples, and it is said to occur in Sardinia.

This scale, by sucking the juices of its host-plants, damages them directly by removing their food substances. The female scale sucks most sap at the end of winter and in early spring, as then it needs it to complete its growth speedily. As a rule, not many specimens of the scale can be found on a given plant ; thus, they cause little damage, but, in certain years and localities, they may attack a plant in numbers, in which case the damage done is proportional to the number of scales and may lead to the death of the plant.

As regards natural causes that hinder the development of *E. coryli*, amongst the first and least active as regards their direct action, are climatic conditions, because temperature, in respect of this scale, cannot cause its death either by increasing or diminishing in the limits within which these

variations take place in Europe. Rain may be directly harmful mechanically if it falls violently at the time when the larvae are hatching and the same applies to wind.

Temperature, rain and manuring can have a greater indirect influence in regard to favouring the development of the insect, because they may put the plant into a state that is favourable or unfavourable to the life of the coccid. The state of the plant that is most favourable to the insect cannot be shown with precision, but an important factor seems to be the abundance and especially the superabundance of sap, because, in the greenhouse, with much watering, a relatively large number of larvae can be got to survive in certain cases. The larvae of the first stage die in large numbers for reasons that are not yet known with certainty.

Amongst the biological conditions that have been noted as unfavourable to the insect, the presence is specially important of certain inidentified fungi that cause their death, particularly of larvae of the first and second stages. The following insects, some of which have been already noted by other authors, are very important in this respect:

a) Coleoptera — *Chilocorus, bipustalatus* L.; *Exochomus 4-pustulatus* L.; *Anthribus fasciatus* Forster.

b) Hymenoptera: — *Encyrtus infidus* (Rossi) Latr.; *Blastothrix sericea* (Dalm.) Mayr, in turn attacked by *Pachyneuron coccorum* L.; *Aphycus punctipes* (Dalm.) Mayr, also attacked by *Pachyneuron coccorum*; *A. philippiae* Masi; *Coccophagus scutellaris* Dalm.; and *Microterys sylvius* (Dalm.) Thoms.

The author gives a biological and morphological description of nearly all these natural enemies of the scale.

480 - ***Coelosterna scabrata*, a Coleopteron Injurious to *Casuarina equisetifolia* in Réunion.** — Lesne, P., in the *Bulletin de la Société entomologique de France*, No. 17, pp. 301-302. Paris, 1919.

The Entomological Laboratory of the Natural History Museum of Paris has recently received from St. Denis, Réunion, some specimens of a longicorn beetle that is injurious, as a larva, to young plants of *Casuarina equisetifolia* in the island.

The author identified this insect as *Coleosterna scabrata* F., a common species in many parts of India, but hitherto unknown in Réunion, where it is apparently a recent introduction.

481 - **Beriberi and Deficiency Diseases.** — SCALA, A. Beriberi e Malattie per carenza, *Rivista critica*, Extract from the *Annali d'Igiene*, Year XXIX, Part. V, pp. 32. Rome, 1919. RURAL HYGIENE

Critical review of the numerous papers published on this subject and discussion of the very diverse opinions expressed on the etiology and treatment of deficiency diseases. The author also expounds the theories that he has formed in the course of his own researches.

After an introduction dealing with beriberi, the first part summarises the papers on the etiology of the disease, experimental beriberi and vitamines, and the specific action of vitamines. In the second part, a detailed discussion is given on the composition of the different foods, the nature of vitamines and their antiberiberic or antiscorbutic action respectively

The conclusions arrived at in the first part are as follows :—

1) Polished rice is really the cause of the beriberi epidemic in places where it is abundantly or almost exclusively used in the ordinary diet.

2) All foods, when eaten alone for a varying length of time, are sure to cause an organic disturbance which finally turns to a true disease of the type of beriberi or scurvy are also varied.

3) These two diseases are caused by the lack, in each food, of *accessory* substances called *vitamines*. These are specific and different for each disease of the above-mentioned group, just as the vitamines that favour growth.

4) The chemical nature of these accessory substances is uncertain and the many authors who have investigated it do not even agree on this point. They apparently are alkaloids of the pyrimidine or hydroxypyridine

group, which decompose on heating owing to a rearrangement of the atoms in the molecule, i. e., the reversible transposition called *physiological isomerism.*

5) The anti-beriberi vitamine is destroyed by heating at 120°C. for a short time and is only slightly changed by heating, even for a long time, at 100° C., Again, the anti-scorbutic vitamine is quickly decomposed when the substances which contain it dry up naturally, as well as by heating to 100° C., or even less, for a short time. The vitamine which favours growth resists even prolonged heating at 100° C. and over.

For these reasons it may be supposed that vitamines or accessory substances in their natural state are not simple substances and that the extracts that have this character, though they undoubtedly have a curative action on polyneuritis, are not true vitamines but different substances which exist either in the same state in the raw materials or as decomposition products of vitamines or other substances.

The author inclines towards the former hypothesis, especially because it is certain that vitamines are not stable, and, consequently, are easily decomposed. : — (*a*) simply by drying (anti-scorbutic vitamine) ; (*b*) by exposure to temperatures of varying height in the presence or absence of water (anti-beriberi vitamines) ; (*c*) by the action of caustic alkalis.

This is by no means of an alkaloid character, but that of enzymes, diastases, toxins, toxo-proteins and special complex substances constituted by two parts, one organic, one inorganic. The author's personal opinion is that vitamines are probably true *colloidal* complexes possessing as well as the properties mentioned above, other special and characteristic properties. In fact, vitamines, like all colloids, are retained so firmly by animal charcoal as to make it impossible to separate them ; they are fixed by aluminium silicate, but can be separated from it by an alcoholic solution of sodium, which is a solvent of organic and protein matter in general ; and they are precipitated by tannin.

Theoretically and practically, so the author thinks, the hypothesis can be supported that vitamines are colloidal complexes, possibly constituted by an organic and inorganic part, and which can provide the central nervous system with the quantity of salts it needs in order to function and maintain the essential equilibria. Again, it is not improbable that deficiency diseases are due to defects in the inorganic nutrition, especially of certain parts of the body, owing to the lack of substances which can transport the salts and act as diastases. This is the cause of the disturbances which, in time, turn to disease and inevitably lead to death.

There is no doubt that when certain salts, or a mixture of certain salts and the ash of cereals that produce beriberi are added to a beriberic ration, the disease is neither prevented nor cured. This, however, is not a final proof, because the salts in question are not in the same form as those in the food, so that they cannot act like them, and cannot nourish certain parts of the organism, for they are at first kept back, then eliminated. In fact, BUNGE found that the value of salts combined naturally with organic matter (complexes) is very different from that of salts not so combined.

When the composition of food materials is examined, not by the crude analysis (which is of limited or at least incomplete biological significance), but by an analysis which takes into account the *state* in which the constituents occur, a fact can be observed which, though hitherto largely neglected, is very important, and which is *the transformation of the organic phosphorus into inorganic phosphorus, accompained by a rise in temperature*, and, *usually, by the decomposition of the complexes by heat or even by simple desiccation.*

Thus, FRANCIS and TROWBRIDGE have shown that cold water extracts the phosphorus in meat at the rate of 52-65 % in the organic state and that, if the solution is heated above 50°C., the organic phosphorus gradually passes into the inorganic condition, while all of it passes into the inorganic state when heated to 100°C. The change from organic to inorganic phosphorus also takes place in milk.

Certain complexes can be decomposed simply by drying ; this is why dry cereal grains contain no anti-scorbutic vitamines, which are very labile complexes liable to decompose more easily than the much more stable anti-beriberic vitamines. However, the former vitamines reappear when the seed germinates, i.e., when synthetic activities recommence.

These facts contradict the generally accepted opinion that vitamines are alkaloids, for the latter are so stable that they are affected neither by drying nor heating to 100° C., or over.

It becomes more and more probable that deficiency diseases are due either to defective nutrition in salts, to the lack of some acid or base, or to the lack of complexes which can transport the inorganic materials. In the case of scurvy, the lacking inorganic matter probably consists of earthy phosphates in the state of complexes that are easily decomposed by heat and drying, while in the case of beriberi, it probably consists of alkaline. phosphates.

The proteins of rice and maize have been accused of incompleteness, thus respectively causing, beriberi and pellagra in persons whose diet is almost exclusively composed of one or other of these cereals. But it has been shown that the protein of rice is almost complete (only tryptophane is wanting) and that it has a food value equal to $^4/_5$ that of milk casein. This protein, therefore, is no more the cause of beriberi than the zein of maize is of pellagra, for a food composed exclusively of maize never produces that disease in rabbits, though it does cause scurvy, as is the case with all the cereals.

CONCLUSIONS. — (1) In considering how beriberi and scurvy arise, great importance should be attached to the inorganic constituents of the ration when they do not constitute a balanced and physiologically complete whole, and when they are not present in the form of colloidal complexes that can transport them to parts of the organism where they could not otherwise penetrate. It is true that no appreciable benefits were obtained by adding to the daily beriberic ration various inorganic materials whether alone, or mixed, with or without organic salts. Again, it is also true, that, in this way, the conditions in which the inorganic materials occur in

the food are not reproduced and that the defective ration is not compensated. Consequently, all the experimental results hitherto obtained are deduced from faulty hypotheses and are erroneous.

2) The continuous use of a single food in which the inorganic matter is not complete, leads to beriberi, which is a form of acidosis, and to scurvy also a form of acidosis, aggravated by the retention of the earthy phosphates owing to the fact that heating has destroyed the corresponding complex which nourishes the bones.

3) The proteins of rice are not the cause of beriberi, and neither is zein the cause of pellagra.

The former are complete, as they contain all the amino acids necessary for the synthesis of animal proteins.

482 - **The Anti-scorbutic Value of Dried and Germinated Seeds.** — CHICK, H. and DELF, E. M., in the *Biochemical Journal*, Vol. XIII, No. 2, pp. 199-218, 5 diagr., bibliography of 16 publications. London, July, 1919.

By means of feeding experiments on guinea-pigs, described in detail by the authors, the following facts were established :—

Evidence was obtained confirming FÜRST's observation that the content of anti-scorbutic accessory factor in dried peas and lentils increases greatly on germination. The anti-scorbutic value of the seeds, after soaking in water for 24 hours and germinating for 48 hours at room temperature is 5 or 6 times greater than that of the same seeds when dried, and, though lower than the anti-scorbutic value of orange or lemon juice, or of the cabbage or swede turnip, it is equal to that of several other vegetables such as runner beans and potatoes, and greater than that of the carrot or beet.

But these seeds, dried or germinated, do not contain sufficient growth promoting factor to give satisfactory growth in the absence of milk from the diet. It seems probable that it is the fat-soluble vitamine that is deficient.

A considerable proportion of the anti-scorbutic power produced in germinated seeds is destroyed by boiling ; consequently, these germinated seeds should be cooked as quickly as possible.

WILTSHIRE (*The Lancet*, London, December 14, 1918) has shown that germinated runner beans can be successfully used in the treatment of human scurvy. The authors quote other proofs, furnished by feeding experiments on human, diets, showing that germinated grains and their products are useful in preventing human scurvy.

483 - **Relative Anti-scorbutic Value of Fresh, Dried and Heated Cow's Milk.** — BARNES, R. E. and HUME, E. M., in *The Biochemical Journal*, Vol. XIII, No. 3, pp. 306-328. Cambridge, November, 1919.

Raw cow's milk is one of the poorest of foods from the anti-scorbutic point of view. Thus, whereas 1.5 to 10 gm. of various raw fruits and vegetables suffices to prevent the appearance of scurvy in the guinea-pig fed on a diet free from other anti-scorbutic foods, from 100 to 150 gm. of raw cow's milk is necessary to obtain the same result. It has been

suggested, based on theoretical grounds, that dried milk should have a still lower anti-scorbutic value than raw milk, while many medical experts state that dried milk is a satisfactory substitute for fresh milk as the sole food for children, with no danger of scurvy from its use. The authors set out to investigate the problem experimentally and have made the following observations :—

Guinea-pigs kept on a diet of oats, bran and milk showed no signs of scurvy ; they did show signs, however, when the milk was replaced by an equivalent quantity of dried milk whether recently made (1 or 2 weeks) or not freshly made (1 to 6 months).

In experiments on monkeys, scurvy was prevented by the use of raw milk and of milk brought rapidly to boiling point then immediately cooled, but it was not prevented when dried milk was used.

Drying deprives milk of nore of its efficacity as a growth-promoting food.

Cow's milk produced in summer is of greater value against scurvy than that produced in winter. This is because of the difference of feeding between the two seasons : grass in the former, oilcake, hay, cereals and roots in the second. Feeding with swedes and turnips, on the contrary to feeding with mangels, apparently gives a milk of somewhat higher anti-scorbutic value.

In consequence, when children are fed with dried milk, they should be given some anti-scorbutic food as well ; the raw juice of oranges, swedes and tomatoes are particularly useful in this respect.

484 - **The Stability of Lactalbumin when Heated.** — Emmet, A. D. and Luros G. O., in *The Journal of Biological Chemistry*, Vol. XXXVIII, No. 2, pp. 257-265 + 7 diagr. Baltimore Md., June, 1919.

Apparently, there exists a certain specific and characteristic difference between the growth-promoting value of casein and lactalbumin. The authors took up the subject with the object of finding whether heat has the same destructive action on the food value of lactalbumin as that observed by MacCollum and Davis on the nutritive value of casein.

The experiments were carried out with rats. The results show that :— (1) High temperatures do not affect the growth-promoting value of lactalbumin as a growth-promoting food if it is dried *in vacuo* at 55° C. or heated in a hot-air oven at 90-100°C. for 16 hours, or in an autoclave at 10 atmospheres pressure for 2 or 6 hours ; (2) the amount of butter fat (5, 18, 28 %) used with the lactalbumin, heated in the autoclave for 2 hours, has no influence on the rapidity of growth ; (3), heated lactalbumin is not toxic to young growing rats ; (4) confirmation is obtained that lactalbumin is of great value as a growth-promoting substance, and the authors put forward the hypothesis that it contains a factor of the nature of a vitamine, but different from water soluble B.

485 - **Availability of Carbohydrates in Certain Vegetables.** — Olmsted, W. H, in *The Journal of Biological Chemistry*, Vol. XLI, No. 1, pp. 45-48. Baltimore, Md., January, 1920.

The extensive use made of certain vegetables with a low carbohydrate content, such as spinach cabbage, cauliflower and lettuce, in a diet for a

diabetic person, makes it desirable to know exactly how much sugar-forming matter is contained in these foods. The author investigated the question in the laboratory of biological chemistry of the Washington University School of Medicine, Missouri, U. S. A. The methods used consisted either in analysis with the use of diastases and copper reduction, or by feeding phlorodzinised dogs to which phlorodzin and adrenaline had been given after 48 hours of fasting (method of SANSUM and WOODYATT, described in the *Journal of Biological Chemistry*, Vol. XXIV, p. 327, 1916). The results are summarised in the appended table, which also gives the results obtained (by difference) in previous work by ATWATER and BRYANT (*U. S. Dept. of Agriculture, Bulletin* 28, revised, 1906).

Availability of carbohydrates of certain vegetables.

Vegetables	Analytical method		
	With taka-diastase	Phlorodzinised dog	ATWATER and BRYANT
Cabbage	4.4 %	5.0 %	4.5 %
Cabbage cooked thrice	0.4	0.5	—
Cauliflowers	2.8	3.4	3.7
Cauliflowers cooked thrice	0.8	0.8	—
Spinach	—	1.2	2.3
Lettuce	1.0	—	2.2

CROPS AND CULTIVATION

RICULTURAL ETEOROLOGY

486 – **On the Thermal Differences between the "Ubac„ and "Adret„ of a Lacustrine Valley.** — GAIN, E. and GAIN, G., in *Comptes rendus de l'Académie des Sciences*, Vol. CLXX, No. 3, pp. 191-194. Paris, January, 1920.

The differences of vegetation found at the "ubac" and "adret" of a valley are usually thought to be the result solely of the thermal conditions :— the sum of useful temperatures, the earliness with which the snow melts away, the earliness of thawing, the duration of direct insolation, etc. The authors have carried out observations on the thermal difference to be found in summer in the climate of the east of France between the two slopes of a lacustrine valley (Gérardmer valley), running approximately from east to west. The slope situated to the north of the "thalweg" (valley floor), and which, consequently, faces south, has "adret" characters which are especially shown by phenological advances in the phenomena of flowering in spring.

On the floor of the valley, the lake forms a large mass of deep water of slight variability as regards temperature in summer. The lake clearly separates the influences totalised by each of the two slopes of the north and south banks. Thermometric observations with the help of special instru-

ments were carried out to the accuracy of 0.125°C. In order to bring out the general bearing of the thermal profile orientated NS perpendicularly to the axis along which the valley is orientated, the authors chose the second part of a dry period that extended over August and September, 1919.

After many preliminary experiments, with the object of avoiding sources of error, the authors took as a basis the simultaneous recording of the temperature of the soil, at 10 cm. deep under vegetation like that of short turf (mowed meadow).

The observation points were at an altitude of 660 to 800 m. This slight difference in level cannot give a regular series of temperatures that decreases as the observer goes higher up the two slopes.

On September 5, 1919, 9.30 a. m. (at 10 cm. deep, in the shade):—

Soil temperatures at the "ubac" (Xetté): 2.25° to 12.5° C.

Soil temperatures at the "adret" (Les Xettes): 13.5° to 15°C.

Averages	Adret	14°25°
	Ubac	13.375°
	A — U	0.875° C

On a hill situated in the valley, a thermal profile orientated east-west gave, in the afternoon, $A—U \times 1.625°$ C.

After one month of summer drought, the differences of the 9 temperatures of the ubac and adret are minimum therefore, and hardly more than 1° C. The authors sought for another characteristic in the temperature of the water draining from the two slopes at the moment when it arrives near the lake.

The authors have repeatedly noted, approximately at the same time, the temperature of the water and of the soil washed by the nine tributary streams, of which 3 at the adret and 3 at the ubac were comparable, having a similar course and flow. The following averages were obtained:—

(1) *Temperature of the water at a depth of* 10 *cm.*:—

Adret	R No. 1	16.5° C.	average 15.16° C
	» No. 2	16°	
	» No. 3	13.25°	
Ubac	R No. 1	14.5° C.	average 13.16° C
	» No. 2	13°	
	» No. 3	12°	

(2) *Temperature of the soil at* 10 *cm. below the bed of the stream*:—

Adret	R No. 1	16° C.	average 15.16° C
	» No. 2	16°	
	» No. 3	13.5°	
Ubac	R No. 1	14.5° C.	average 13.25° C
	» No. 2	16°	
	» No. 3	12.25°	

Difference between the adret and ubac: $A — U = 1.91°$ C.

The temperatures were also taken of the springs, the water of the lake and of the lake side; these were:—

(1) *Minimum temperature of the spring* :—

At the adret (Haut des Xettes)	10.25° C.
At the ubac (Roche du Lac)	7.25° C.
$A - U$ =	3°C.

(2) *Temperature of the (surface) water of the lake* : 19.5° C.

(3) *Temperature of the air one metre above the soil* : 20° C.

(4) *Temperature of the shores of the lake* (September 3, 1919, 10.30 a. m.) :—

	Dry soil in the shade shore wave-washed	Limit of soil wet by lake	Stream water	Lake water near the shore
Adret	14°C.	16.75°C.	13°C.	18°C.
Ubac	12°–12.50°	12.5°	12°	17°
$A - U$ =	1.5°–2°C	4.25°C	1°C	1°C.

487 – **Experiments in Agricultural Meteorology Relating to Wheat made at the Higher Agricultural Institute, Lisbon.** — FIGUEIREDO FILIPPE, E. A., in the *Boletim da Associação da Agricoltura Portuguesa*, Year XXI N.o 8, pp. 251-264. Lisbon, August, 1919.

The latest observations confirm the previous discovery made by the author of the existence of an inverse ratio between the yield and rainfall during growth. Similar conclusions have also been arrived at by TELES DA SILVA MENEZES, Director of the Agricultural Station of Figueira da Foz (1918-19).

It was found possible to deduce with the greatest accuracy from observations extending over 7 years the following critical period :— The February rains have the most marked action on growth, and years of good and bad harvests coincide exactly with the years having a dry and rainy February, respectively.

In 1918-1919, wheat was sown thrice in the experiment field, once on December 15, once on February 1, and once on March 1. The following crops were obtained :—

December 15	7.5 times the seed
February 1.	8.0 » » »
March 1	9.7 » » »

The distribution of the rain was as follows :—

	Crop in		
	December	February	March
From first rains to sowiug	35.9 mm	295.4 mm	338.9 mm
From sowing to coming up	71.6	39.9	36.5
From coming up to tillering	**186.7**	**16.2**	**11.7**
From tillering to earing	179.9	135.2	107.3
From earing to harvest	20.3	7.7	0.0
Total (from sowing to harvest) . .	**458.5** mm	**299.0** mm	**155.5** mm

It will seen that, in every case, the rain is scanty during the critical period of growth. In the years of good harvest, in fact (13.7 times the seed), the rainfall between coming up to tillering is, on an average, 325 mm.

But, on account of the favourable conditions as regards rain (especially the March sowing), the harvest was that of poor years. The cause is the almost absolute lack of rain during the period from earing to harvest, aggravated by a sudden rise in temperature in the second half of May or in the first half of June. There was thus slight lodging, and the grains, owing to hastened ripening were badly formed and of inferior quality.

488 - **The Drought in 1919 in Touraine (France) and its Effects on the Vines, particularly on Direct Hybrid Bearers.** — CHAUVIGNÉ, A., in the *Revue de Viticulture*, Year XXVII, Vol. I,II, No. 1342, pp. 197-199. Paris, March, 1919.

In 1919, there was a very rare and highly interesting meteorological case, in so much as a drought compaiable to that of 1893 put to test the different vines that are studied and preferred by many growers.

It may be said that, in Touraine, April 15 was the end of a long period of rain, which had soaked the soil with water that took a long time to soak into the subsoil. Except for a few successive stormy downpours, the dry season began at that moment. The heat increased on May 10 in an unbroken wave that reached its maximum on June 11 with a minimum of + 12° C in the night, a maximum of + 33° C in the shade at noon, and + 50° in the sun among the vines... A temperature of as much as + 52° C was even registered at noon in the sun on June 16.

After that date, the heat diminished, but not a drop of rain fell until June 25, after which, up to August 8, there were only a few slight showers, which were so eagerly absorbed by the dry ground that no traces were left. Then began the period of great heat, which reached its maximum on August 13, 14 and 15, with temperatures of at least 16.5° C at night, +32° C in the shade at noon and 50°C. in the sun. This heat afterwards decreased, but the period without rain lasted until the showers on September 20, and the more abundant rain on Sept. 27 which decided the fate of the crop.

The grafted vines and the hybrid direct bearers behaved differently with regard to the drought.

The " Cots " and " Bretons " as well as the " Grolleaux ", in spite of their great resistance, showed the effect, especially in arid soils, by the drooping of their leaves. The bunches ceased to develop, the grapes did not increase in size, growth was slowed down, and no advance towards maturity was made until the first rains in September. In the following fortnight, the basal leaves, which were still green, regained vigour, the grapes developed normally, although late, and the harvest was plentiful and of good quality.

By means of a comparative examination, the author found that this was by no means the case with hybrid direct bearers.

At first, at the moment when the floral clusters emerged, it was noticed that their number was somewhat reduced and that, whilst the French vines had vigorous bunches with fine petals, the hybrid bearers had only small ones. Then the drought came, and soon profoundly affected the hybrids in every part ; the leaves, for the most part, dried up, showing that growth was entirely stopped. The bunches had undeveloped grapes consisting of fleshy, very acid pulp enclosed in a thick, tough skin.

When the rains came and decided the fate of the crop, it was found that they had come too late, as the drooping leaves no longer fulfilled their active function and the grapes remained small and miserably drooping.

All the hybrids without exception were severely tried, particularly white and red Seibel, Baco, Malègue 1157-1 and Girerd 157.

As regards fungoid disease and scorching, it can be said that, as the season had been so dry, disease hardly appeared, and there was practically no mildew and just a few attacks of oidium. Though the direct bearers did not suffer in this respect, the same cannot be said of scorching, which affected practically all the vineyard, fairly severely in certain regions, and caused an appreciable loss of the crop.

The sudden heat on August 10 with + 52° C in the sun and on August 15 with 50° C, after a dull period, caused this damage to the uncovered bunches which were then in an awkward period of growth. The hybrids were severely tried because they themselves had no resistance.

489 – **The Behaviour of Certain Grafting-stock as regards the Great Drought of 1919, in the South of France.** — See No. 532 of this *Review*.

SOIL PHYSICS, CHEMISTRY AND MICROBIOLOGY

491 – **Calcium and Magnesium Content in Virgin and Cultivated Soils in Ohio.** — AMES, J. W. and SCHOLLENBERGER, C. J. (Ohio Agricultural Experiment Station), in *Soil Science*, Vol. VIII, No. 4, pp. 323-335, bibliography of 8 works. Baltimore, 1919.

The authors have estimated the contents of total and N/5 nitric acid soluble calcium and magnesium as well as the carbonate and soil reaction of both cultivated and virgin soils in 23 localities in Ohio.

The analytical data show that, in the majority of virgin soils, there is a concentration of easily soluble calcium and magnesium near the surface, whilst, in cultivated soils, the subsoil contains more of these elements than the surface soil.

There are certain interesting relations between the proportion of the total soluble calcium and magnesium and the content of carbonate, as well as the soil reaction. Thus, when the proportion of the total soluble calcium and magnesium together, is relatively high, the soil often contains more carbonate and is more basic than similar soils containing a smaller proportion of soluble bases and this fact holds good for soils with a low percentage of carbonate as well as for those with a high percentage.

492 – **Absorption of Soil Constituents by Plants at Various Stages of Growth.** — Burd, J. S. (Professor of Agricultural Chemistry, College of Agriculture, University of California), in the *Journal of Agricultural Research*, Vol. XVIII, No. 2, pp. 51-72 + 1 Fig. + Bibliography of 9 works. Washington, D. C., 1919.

Experiments were made with Beldi selected barley grown on a silty clay loam and on a fine sandy loam respectively in 1916 and 1917, and the composition was analysed at various stages of growth.

In spite of the diversity of soil and harvest, a considerable parallelism was observed between vegetative growth and the successive changes of the rate of absorption of the plants. Thus, a large absorption was noted in the first stage, then a notable loss of potash and nitrogen in the plant in the second stage of growth ; then there is a fresh period of absorption, while, in the third stage, absorption practically ceases. The losses took place when the constituents of the aqueous extracts of the soil were at a minimum or close to it, and when the constituents migrated from the leaves to the ears.

The authors are of the opinion that a high concentration of the soil solution is unnecessary and is even undesirable at certain stages of the growth of many plants. They suggest that the research method followed with barley should be applied to other plants in the hope of obtaining data for the more rational formulation of experiments with sand and water cultures.

493 – **The Effects of Zinc in Experiments on Soils Contained in Zinc and Galvanised Iron Recipients.** — Conner, S. T. (Dept. of Soils and Crops, Purdue University Agricultural Experiment Station, Lafayette, Ind.), in the *Journal of the American Society of Agronomy*, Vol. XII, No. 2, pp. 61-64 + Bibliography of 9 works. Washington, 1920.

During experiments with acid soils, in zinc and galvanised iron pots covered with paraffin wax, the crops in the second season unexpectedly decreased. On examining the literature on the subject, it was seen that zinc has usually a toxic action on crops and, in fact, the experimental soils were analysed and found to contain zinc in harmful quantities when they were not limed, while, in those that had been given plenty of lime the zinc content was appreciably reduced. Thus, the acid soils in the pots contained from 0.021 to 0.088 % of zinc according to the acidity, while, in limed and non-acid soils, the zinc varied between 0.001 and 0.002 %.

These results can be explained by the fact that the paraffin wax coating of the pots had a granular structure, so that the acids of the soil could pass through and form zinc salts. No really protective and efficacious covering has yet been found, and for this reason zinc should not be used with acid soils. The action of acid soils on the zinc shows that these soils really contain acids, i.e., their acidity is chemical and not physical owing to selective absorption.

494 – **The Use of War Explosives for Industrial and Agricultural Purposes.** — Garibaldi, C., in the *Giornale di Chimica Industriale*, Year II, No. 1, pp. 10-22 + 9 Figs. Milan, 1920 (1).

Explosives which, owing to their chemical composition and their structure, burn rapidly and which, by their lively and instantaneous combustion,

(1) See *R.*, 1911, Nos. 2529, 3135 ; 1912, Nos. 671, 777, 1398 ; 1913, No. 230 ; 1914, No. 1092 ; 1917, Nos. 107, 1000 ; 1919, Nos. 19, 685, 821, 1091. (*Ed.*)

give off gases at high temperatures and produce considerable pressure, are usually considered as mining explosives, whose action is to split up by the explosion. Amongst the commonest ones, which have long been used industrially for piercing, demolishing and destroying heavy, cumbrous materials, for rectifying canals, work on mines, roads, etc., the different grades of dynamite and special black powders have so far taken first place. Several more or less successful attempts have been made to adapt these explosives to agricultural use.

In 1870, DE HAMM, at Vienna, suggested the use of dynamite in agriculture. In 1878, ASCANIO SOBRERO, the inventor of nitroglycerin, published in the *Annali della R. Accademia d'Agricoltura* of Turin, the results obtained by using dynamite for agricultural purposes and he also gave instructions to farmers in the use of this explosive for breaking up land. As various disadvantages became apparent, and as the process was not generally adopted at that time for various reasons, without counting the absolute need of special knowledge and skilled workmen, these experiments were not received with great interest in the agricultural world. Several years passed, during which these experiments, if not completely abandoned, were at any rate somewhat neglected, until the subject was bravely taken up again and applied on a large scale first in America, where an industry actually sprang up, and developed so that, in 1911, a single works in the United States sold 3 millon francs' worth of dynamite solely for breaking-up soil. Similar uses were tried in Europe, and Italy also followed this example. The use of dynamite and black powder, for felling trees, opening roads, excavating in rock and destroying bridges has always been peculiar to military services.

Up to the present, dynamite has always been the explosive used in agriculture, whilst the modern explosives brought forward by the recent war have only been used for military purposes. Now, there are huge stocks of them which cannot be utilised and which are easily subject to dangerous changes. New experiments have been made with these explosives, using past experience as a guide, and as these cannot be costly now, the object of the experiments was to help the farmer to carry out work that he could not accomplish solely by ordinary means.

The explosives that have been tested thus can be divided into three groups :—

1) Progressive firing explosives, using as a basis, nitroglycerin, balistite and solenite, in sheets, slabs or threads.

2) Trinitrotoluol (tritol, T. N. T.), which requires a detonator ; in crystals or granules, compressed or melted into blocks.

3) Trinitrophenol (picric acid), also requires a detonator ; in crystals or fused in blocks like T. N. T.

After having tested these new explosives destined for mines in their special use, and after having found that they could replace dynamite, which is now very expensive to make, the tests were turned to agricultural purposes, in order to find whether they could be used for breaking up so much land which henceforth need no longer remain uncultivated.

The first experiments were made on arid, compact, stony soil, which had never been worked and was capable of breaking the coulters and twisting the share of the best of ploughs.

Several holes, 70 cm. deep, were made in a plain of this nature and cartridges with 20 gm. of powdered T. N. T. were placed in each hole. The explosion reduced the soil to fragments within a diameter of 1.80 metres and more, and disturbed the soil all round in a circle of at least 50 cm. The soil was all broken up to a depth of 2 metres and signs of disturbance were found deeper still.

Dynamite and black powder do not behave as well in this soil as in hard rock, as they need compactness in order to develop all their strength.

After the way in which these explosives act in soil was ascertained, a large number of tests were made.

Sixty holes, 30 mm. in diameter and 40 cm. deep, were made, always in soil of the same nature, and 20 were charged with balistite, 20 with T. N. T. and 20 with picric acid, each in 100 gm. cartridges. The result was 60 holes full of broken soil, always most broken towards the bottom, the soil being as finely broken up as if it had been done by hand. Sixty other holes were loaded with the same explosives, in the same amounts and under similar conditions to the preceding ones, but at a depth of 60 cm. The explosions were not so loud and less soil was thrown up.

Further experiments were carried out with 60 mines loaded in the same way, but at a depth of 80 cm. The explosions were very dull and almost unnoticed, little or no soil was thrown up and while the cavity formed in the previous tests was shaped like a glass or cylinder, in this case all that was found was the surface soil cracked all over ; just below, however, there was a flask-shaped hole ending in a point at the bottom, as much as 1.20 metres deep, and with a diameter of about a metre, round which the soil had been much disturbed up to the surface, as in the previous cases. In this experiment, picric acid was found to be the best, as its action was felt over a wider zone than that of the other explosives. Whilst balistite, with slower combustion, had broken up the earth splendidly at a slight depth, the other more rapid explosives were better, when placed deeper down in a harder soil and with greater resistance to overcome.

The explosives tested gave different results in soil according to the depth at which they were placed, not so much on account of their chemical composition and mechanical action as of various physical factors amongst which the density is directly or indirectly of the greatest importance.

From the results showing the different behaviour of the explosives as regards the charge and the effects produced at different depths and under different conditions, the authors deduced accurate rules for working larger areas of land which previously had been left uncultivated owing to the great cost of bringing them under cultivation. For breaking up compact soils which will be used for growing herbaceous crops, for which the soil does not need to be moved to any great depth, balistite is the best explosive to use, because it does what is required of it over a larger cultivable area, while T. N. T. and picric acid are more suitable for such work as excavating

holes for planting trees. It should not be forgotten that all the above experiments were carried out in soils of the same nature. If the soil and the charges are varied, the same explosives will produce other types of broken-up land which are always less efficacious from the farming, standpoint, the more so as the soil becomes less tenacious, porous, light and less compact in type.

Again, if the holes are made at greater distances apart, up to 2 metres in every direction, and at a depth of 70 cm. with 100 gm. charges, the cones of soil left intact between the mines are bigger and have, in this case, a resistance that may cause trouble.

But if the rows of holes alternate, instead of being arranged parallel in squares, the volume of the cone is much reduced and, if the land has been mined with picric acid or T. N. T. (as these break up the soil very much at a certain depth, with the formation of flask-shaped holes), when the plough passes over these inverted cones, almost suspended in space, it then breaks them down and mixes them with the rest of the soil. Over a hectare of soil that was considered to be impossible to work, was mined in alternate rows on this system, and it is now completely cultivated, ploughed and ready to be sown.

It should be remembered that, in sloping ground, the explosion undoubtedly produces most effect if a fairly heavy charge is fired in the lowest range of mines, following it in the different rows with the normal charge; the direction should never be from the top rows to the bottom ones. In the first case, the explosion forms a chain of fairly pronounced ditches, and in any case the soil is shaken. The second row, finding the weak spot, explodes towards the first; similarly the third row explodes on the second and so on. In this way, the soil is mixed more intimately, and along the last row to be exploded, a furrow can be seen that might have been opened by a plough. This conformation can exist in flat land, but not to such an extent, as there is no slope to help in producing it. Again, in all soils, particularly those with slopes of varying steepness, the explosive is more effective according to the direction in which the mine points. Where there is a slope, the holes should never be made in a direction perpendicular to the horizon, but should always be inclined according to the slope of the soil. Even in flat land the holes should not be vertical but inclined to one side.

Experiments in damp, sandy soils of a softer nature are of no interest, as such soils can be worked by hand. In damp soils, T. N. T. and picric acid require special precautions, but if they are not exposed to these exceptional conditions for long, they act just as well as in damp soil. In soft soil, T. N. T. and picric acid only hollow out caverns, and even ordinary balistite is too energetic. It also also worth remembering that if the cavities produced by the explosion in hard, stony soils are surrounded by zones were the soil is extensively cracked (which assists the growth of tender roots and helps them to become vigorous, while enabling the excess water to drain away or the absorption of the water required by the plant), in soft soils, especially damp ones, the explosion projects particles of soil

from the centre of the zone of the explosion into the pores of the surrounding earth, thus producing a hard, compact wall with a smooth surface ; this physical condition is worse than the previous one.

Experiments carried out in the United States, in Australia, Malaya, Ceylon, Switzerland and England negative the hypothesis that land worked by means of explosives is poisoned and thus injurious to plant life. The lack of plant life on shell craters is no proof to the contrary, firstly because allowance must be made for the shock of the wave produced by the explosion of enormous charges on the ground and for the high temperature of the gases generated. At greater depths, and with time and the action of atmospheric agencies, only a minimum part of these gases can be absorbed by the soil and afterwards changed to salts, whilst the greater part escapes through cracks and openings into the air. Again, if vegetation wis absent or even scanty, it soon reappears and shows more vigour than ever. As regards the decomposition products of the explosives in question, they are of such a nature as to leave no room for doubt. Picric acid gives off carbon dioxide, carbon monoxide, hydrogen, methane and nitrogen ; T. N. T. gives off carbon dioxide, carbon monoxide, hydrogen and water, while the balistites and the powders based on nitroglycerin and nitrocellulose give off the same gases, with the exception of carbon monoxide.

From the economic point of view, the use of explosives for working hard, compact, rocky soils is generally the best, especially for work that does not require a general and continuous breaking up, whether on the surface or in the subsoil, but which needs a partial displacement of the soil, limited to narrow strips for ditches, small areas for plantations of trees, for absorbent wells, for removing tree stumps, etc.

Explosives, by lifting the soil within a certain radius and splitting up the layers in all directions, makes it easy for ploughs to continue in the following year, because they leave the soil porous and absorbent in its deepest parts and give life to abandoned and uncultivated areas by enriching the soil with a bumper crop the first year, thus giving it a value it had never had before. The economy due to the use of explosives, compared with the cost of tilling the ground with the usual implements, varies from 25 to 30 %, and if the ever-increasing cost of manual labour is taken into account, these figures can be increased by another 15 %.

In order to obtain good results from the use of explosives, it is absolutely essential that the person directing the work should know the best practical methods, while keeping in mind the results of previous experiments, as the quality and quantity of explosive and the method of preparation vary according to the nature and qualities of the soils and according to the objective desired.

So that the work can be done cheaply, improved apparatus is required and a number of detailed official regulations which might prevent continuous, profitable work should be altered so as to help agriculture. Again, the cost of the explosives should not be too high, as the cost of the work depends largely upon the help it affords.

In Italy, especially in the Roman Campagna, in Apulia, Calabria,

Tuscany, the province of Ferrara, etc., there are hundreds of thousands of acres of uncultivated land, which remain untilled simply because, with the available methods, the resulting profit would not cover the expense, and because the machines most adapted to the purpose would not give better results. Were these soils all cultivated, Italy would be self sufficient, as she would produce possibly more than her own needs, and as much money would not leave the country. Since the Italian Government actually possesses enormous quantities of explosives as war surplus, the author hopes that the experiments now being carried out in various regions of Italy for the benefit of agriculture will attract the attention of the Government, which ought to encourage and support the attempt to find the best solution of the question of using explosives for the benefit of farmers and the whole country.

PERMANENT IMPROVEMENTS DRAINAGE AND IRRIGATION

495 - **The Problem of Drought in the North-East Region of Brazil and the Measures taken by the Brazilian Government.** — I. O problema das seccas no Nordeste Brasileiro, A meusagem do Sr. Presidente da Republica, *Republicas dos Estados Unidos do Brasil, Boletim do Ministerio das Relações Exteriores*, No. 3, pp. 59-62. Rio de Saneiro, September, 1919. — II. Id., A iniciativa do Governo para a sua solução, *Ibid.*, No. 6, pp. 59-60, December, 1919. — III. BRAGA, E., Seccas do Nordeste e Reorganização economica, p. 88. Rio de Janeiro, 1919 (1).

The rainfall in Brazil is very evenly distributed, for the greater part of its area constitutes a typical zone as regards humidity. An exception, however, is furnished by the north-east region which projects into the Atlantic and is somewhat distant from the coast. There we find a semi-arid zone surrounded by a semi-humid belt which stretches from the north of the State of Minas Geraes to Ceará. This zone is subject to intermittent drought, the cause of which is not so much the absolute lack of rain as its irregular distribution, and it corresponds to the trade-wind zone of the central Atlantic.

This problem was very carefully considered by the Brazilian Government after the great drought in 1877, which caused the loss of many human lives as well as large amounts of rural property. With the object of preventing harm from drought in this region, the Government, in 1909, set up an "Inspectorate of works against drought", whose preliminary task was to study the problem from the physiographical point of view, not forgetting practical measures such as forest and forage crops, the construction of roads, reservoirs and dams, the provision of wells, fish-breeding, etc.

Without interfering with this plan, the Brazilian President, Dr. EPITACIO PESSOA, in a message quoted at the beginning of the article, considers

(1) See also: — DELGADO DE CARVALHO, C. M., Brazilian Meteorology, p. 528. London, 1917; MOREZ, H., Etat actuel de la météorologie agricole au Brésil; *Review of Agricultural Information and Plant Diseases*, Year IV, No. 9, pp. 1356-1358. Rome, 1913; CRANDALL, R., and WILLIAM, H., Carta pluviometrica da Região semi-arida do Brasil. Rio de Janeiro, 1910; BORGHESANI, G. H. R. Planisfero udometrico dell'irrigazione. *Commissione Reale per studi e proposte relative ad opere di irrigazione, Seconda Relazione*, Part. III. Bergamo, 1916.

that, on the basis of the good results obtained in Egypt, India, and the United States, the reclamation of desert lands is equally possible for the area of Brazil in question, and that the public authorities should preferably pay attention to the conservation and utilisation of the water resources by means of large dams and reservoirs. The cost of this would obviously be enormous, but experiments made in other countries show that part of the cost could be recovered in a few years by the increased revenue from taxes, owing to the greater value of irrigated land and to the greater prosperity of the population. The fear that there would be insufficient water to feed the reservoirs in such a way as to make them really useful cannot be justified, as a lengthy study of the hydrometrical conditions in the state of Ceará, which is least favoured as regards this, revealed an annual precipitation of 80 milliard cu. metres, 16 milliards of which could be gathered and used for irrigating over a million hectares. For this reason, sanction is asked for the emission of a loan of 67 200 000 fr. a year (par value), until a total of 336 million fr. is reached. This money will be used for the construction and upkeep of large reservoirs of irrigation canals and supplementary works necessary for irrigating the cultivable soils in the north-eastern region of Brazil.

The Brazilian Congress has recently passed a decree authorising the creation of a special reserve to provide for necessary expenses as well as for the interest on and the amortisation of the loan mentioned above. The fund will be formed by :— *a*) 2 % of the general revenues of the Republic during the period required for carrying out the work ; *b*) 2-5 % of the ordinary revenues of each state interested, to be laid out, with the previous approval of the Federal Government, either in cash or in public lands ; *c*) the proceeds of the sale of land ceded by the states or of lands that could be expropriated ; *d*) the revenues from irrigation work ; *e*) contributions from any other source.

Land required as sites for irrigation works, inundated land and forests necessary for the conservation of watercourses will be considered as of public utility as regards expropriation.

The Federal Government will exploit and administer the irrigation works until the cost is fully repaid. Irrigation and maintenance taxes will be established as well as rent for the expropriated land. If the owners fail to cultivate their lands in accordance with rules laid down by the Government, such lands will be confiscated, as they will also be if no taxes are paid for 2 years. Again, when confiscated land is sold or let, preference will be given to the families of farmers who live in the state in whose territory the irrigated land is situated ; in any case only small areas will be ceded.

At the same time, the Government will attach agronomists and veterinary surgeons to the agricultural services of the area in question and will provide the farmers, either by loan or by sale, with the tools, seeds, fertilisers and everything needed for improving the fertility of the soil and to preserve, utilise, transport and market its products.

M. C. Braga, a Federal Deputy, showed, in a statement made before the Finance Commission of the Brazilian National Congress, that stock

rearing offers better prospects of success in north-eastern Brazil than cotton growing and irrigated crops. He estimates that one irrigated hectare under cotton, yields 12 quintals of cotton worth about 900 fr., whilst one hectare down to pasture for fattening stock will yield 850 fr.; this slight difference is more than compensated for by the manuring of the soil, by the smaller risk and by a lower cost.

On account of the great irregularity of the rainfall, shown by the following table: —

Rainfall in four typical localities.

	I	II	III	IV
1904	1 265 mm	230 mm	456 mm	1 134 mm
1905	1 467	463	383	1 131
1906	1 773	487	737	1 579
1907	837	245	391	715
Yearly averages	**1 280 mm**	**375 mm**	**456 mm**	**1 123 mm**

M. Braga considers that the transport question is of immediate importance and that a suitable network of railways and carriage roads would, in years of drought, enable the population to emigrate from one zone of a region to another with more abundant rainfall, so that the 30 million inhabitants and the livestock of north-eastern Brazil would, if they desired, have a possible outlet towards the large irrigation centres suitably distributed over the country. As no great irrigation scheme is exclusively based, with a few exceptions, on rainfall, but rather on water derived from permanent rivers, and considering constructional difficulties M. Braga thinks that it would be best to construct the three largest reservoirs for each of the three States that suffer most from drought, viz., Ceará, Rio Grande do Norte, and Parahyba, and if they give good cultural and social results, there would be no reason to prevent their extension and development.

496 – **Irrigation of Field Crops: Experiments in Nevada, U. S. A.** — Knight, C. S. and Hardman, C., in *Bulletin* No. 96, *Agricultural Experiment Station, University of Nevada*, pp. 42, 20 Figs. Carson City, Nevada, 1919.

Discussion of the methods of irrigation used in Nevada; water supply and area irrigated by the State; factors affecting the results of irrigation water; description of experiments on irrigated field crops including alfalfa, wheat, potatoes, red clover and sugar beet.

In 1918, 900 000 acres or about 1.3 % of the area of Nevada was irrigated, and produced approximately some 145 000 acres of alfalfa, 80 000 acres of wheat and 15 000 acres of potatoes. The chief rivers that supply irrigation water are the Humboldt, Truckee, Carson, Walker, and Muddy; the Humboldt waters over half the total irrigated area.

Most of the alfalfa and cereals acreage is irrigated by flooding, while potatoes and other hoed crops are irrigated by means of irrigation furrows.

The chief factors that influence the effect of the irrigation water are the type of soil, its topography, the presence of a crust near the surface, the annual rainfall, and evaporation. The soil type causes more variation in the quantity of water required for irrigation than any other factor.

The average results of the experiments made with alfalfa during the period 1906-1911 show that with a total consumption of 3.27 acre feet of irrigation water, a yield of 5.93 tons of hay per acre is obtained. In the 5-year period 1914-1918, there was not sufficient rainfall during the growth period to influence the soil-moisture content of the soil. When irrigation was delayed until the alfalfa began to wither, the unit yield was relatively low; there was, however, a very high yield when irrigation was practised when the plants had only assumed a dark colour. The most economic irrigation for alfalfa was accomplished with a total irrigation of 3.5 ft., of water, each time the plants showed need of water by turning dark green in colour.

Soil moisture determinations showed that, with an irrigation of 6 in, of water, 70 % of it was retained in the first 4 ft., of soil; but with this, the lowest crop per unit volume of water consumed was obtained, or 6.18 tons of hay per acre for a 81 in., layer of water. Soil moisture determinations also showed that only 25 % of a layer of 12 in., of water was retained by a surface layer of soil 4 ft., deep. In irrigated alfalfa fields, the decrease of the soil moisture content at mowing time was generally greater when 9 and 12 in., of water were given, while the total quantity of irrigation water retained in the soil was greatest at the time of the two last periods of wilting.

In experiments made with wheat during the 5-year period 1914-1918, 3 and 7 in., was given during two or more of the typical growth periods, i. e., appearance of the fifth leaf, ear formation, flowering, milky consistency of the grains, pasty consistency. The maximum yield was obtained with 28 in., of water in four applications, omitting that of the period when the fifth leaf appeared. The maximum yield with 3 irrigations was obtained with 21 in., of water, omitting the irrigations given during the first and last of the above-mentioned 5 periods. The average yields of wheat were considerably higher when 7 in., of water was given than with 3 in., at each irrigation. The yields were relatively low when the irrigations of the ear-formation and flowering periods were omitted, which shows a very critical period for wheat as regards its need for water, between ear formation and the period when the seeds are of a milky consistency. The highest yield was obtained by giving 9 in.. of water in 2 irrigations, one before and one after earing. High unit yields were usually accompanied by the greatest decrease in the soil moisture content at harvest time compared with the soil moisture content before the first irrigation.

In the experiments with potatoes, continued during the 4-year period 1914-1917, the heaviest crop was obtained with a total irrigation of 16.5 in.,

of water, distributed in 3 in., applications when the plants showed a tendency to wilt.

Irrigation experiments with clover showed a gradual decrease in yield in as the wilting period of the plants advanced at the time of irrigation.

Sugar beets gave the heaviest crop with 18 in., of water in 3 in., applications.

The results show, generally speaking that the most economical use of water consisted in giving a total of 3.5 ft., at the rate of 6 in., per time for alfalfa and clover ; with a total of 2.3 ft., in 3 in., a time for application for wheat with a total of 1.5 ft., in 3 in., applications for potatoes and sugar beets. When alfalfa is used for autumn pasture after the last mowing, usually an extra irrigation is required after the last harvest.

MANURES AND MANURING

497 - **The Preservation of Liquid Manure.** — KRISTENSEN, R. K., in the *Tidsckrift for Planteavl*, Vol. XXVI, Pt. 3, pp. 485-490. Copenhagen, 1919.

The Danish State Agricultural Experiment Station at Askov has carried out experiments on the preservation of liquid manure by adding sulphuric acid or superphosphate.

The liquid manure used contained 0.478 % of nitrogen, of which 0.418 % was present as ammonia. It was placed in porcelain dishes and evaporated on a water-bath ; a series of 5 cc. samples was treated with from 0 to 32.5 cc. of decinormal sulphuric acid and with from 0.1 to 1.5 gm. of 18 % superphosphate.

The results obtained showed that two-thirds of the acid used was retained by the ammonia, and the rest by the other bases. Very small quantities of acid had practically no effect on the conservation of the ammonia ; in order to fix all that contained in the 5 cc. sample, 1.3 gm. of superphosphate or 22.5 cc. of decinormal sulphuric acid was required.

498 - **Experiments and Researches on "Tetraphosphate".** — MENOZZI, A., in the *Giornale di Chimica Industriale*, Year II, No. 1, pp. 8-9. Milan, January, 1920 (1).

Some tour years ago, a product called "tetraphosphate", made and marketed by a company bearing the same name, gave rise to a large number of publications and to much discussion, Publications in its favour upheld and still uphold that it has the same fertilising value as superphosphate, but without the acidity of that product which is so injurious to certain soils and harmful to the bags, and that it provides phosphoric acid at a cheaper rate than superphosphate.

After a chemical and petrographical examination of a few samples the author, in a public lecture given in May, 1916, at the Higher School of Agriculture at Milan, expressed the opinion that it is substantially nothing else than phosphorite. This announcement led to discussion even at the lecture ; interested persons held that the samples sent to the laboratory were probably not indentical with the commercial product, that i

(1) See *R.*, 1916, No. 1063. (*Ed.*)

was not purely a question of phosphatite, but of phosphorite radically changed by tratment, and that, in addition, practical tests had given results favourable to the new product. The representatives and manufacturers of superphosphate then suggested that a commission, presided over by the author, should study the product in detail by means of cultural tests. The representatives of the tetraphosphate company accepted the proposal and the commission was set up. It has now published a report on its work and on the cultural tests carried out during 1916-17 and 1917-18. A summary of the report is given below.

In accordance with the plan decided on, the commission saw the actual preparation of the product which, according to the patent specification, consists essentially in mixing ground phosphorite with 6 % of a mixture, known as the " reagent ", composed of calcium and magnesium carbonates, sodium sulphate and carbonate ; the whole mixture is heated in a furnace and the mass while still hot is hydrated. The process took place in a special plant belonging to the superphosphate factory of the co-operative agricultural consortium of Lodi (Milan).

The commission took samples of the phosphorite and of the mixture of phosphorite and reagent before heating and of the product obtained after heating and hydration ; these samples were examined chemically and petrographically, in the latter case by Prof. Artini, director of the municipal museum of Milan. The results of both the chemical and petrographical examinations showed that no chemical or structural change had taken place in the raw material (phosphorite,) during heating and subsequent hydration, under the conditions of manufacture as seen by the commission. Neglecting the salts added in the " reagent ", the original phosphorite was still to be found.

In spite of this, the commission, admitting that some fact might have escaped notice and wishing to neglect nothing, decided to make comparative experiments in pots, boxes and in the field, with different plants and soils. The report gives full details of thse experiments and here it may simply be said that, in each test, with the same plant and the same soil, the same potassic and nitrogenous fertilisers were given in equal amounts, and that comparisons were made between the different phosphatic fertilisers, i. e., phosphorite, tetraphosphate, and superphosphate, which were given in such a way as to contain equal amounts of phosphoric acid and in a pot or plot, the same treatment with nitrogen and potash, save that no phosphatic fertiliser was given.

The fineness of division of the tetraphosphate compared with that of superphosphate was examined, but only negligible differences were found on carrying out laevigation.

None of the tests made in 1916-1917 gave positive results, for not only were the differences between the various phosphatic fertilisers slight, but they were also slight between the pots with phosphatic fertilisers and those without phosphates and, in one experiment, the control produced more than the pots or plots given fertilisers. This may possibly be due to the fact that, on analyses, carried out during the tests and not previous to them (in

order to save time), the soils used were found to be all relatively rich in phosphoric acid, viz., from 1.25—2.20 per 1000 of soil. Therefore, definite conclusions cannot be drawn from these tests.

On the contrary, however, significant results were obtained in 1917-1918, in which year several tests had to be discarded, because, in one case, the crop was ruined by hail and in others because the crops were damaged by parasites. But all the other tests were completed without hindrance, and definite conclusions can be drawn. The yields obtained in 1917-18 show that : — phosphorite and tetraphosphate always produced a little more than the control with phosphatic fertiliser ; that both were always inferior to superphosphate ; that there were only slight differences between phosphorite and tetraphosphate, and these mostly came within the limits of experimental error.

499 – **Fertilising Value of "Broom Millet". Ash** — Guthrie, F. B., in the *Agricultural Gazette of New South Wales*, Vol. XXX, Pt. 10, p. 735. Sydney, 1919.

The ash of broom millet is comparatively rich in potash and, with the present price of 15 *s.* per unit of potash, a ton of the ash is worth about £. 11, though, under normal conditions, this figure would only be about £. 3.15*s.* It should not be forgotten, however, that the ash contains about 4.5 % of phosphoric acid.

Analysis of sagine ash.

Moisture	2.59 %	Potash	15.53 %
Insoluble	57.23	Soda	1.07
Oxide of iron and alumina	3.73	Phosphoric acid	4.67
Lime	6.11	Sulphuric anhidride	2.46
Magnesia	3.53	Carbonic acid	2.40
		Chlorine	0.77

500 – **Sulphur as a Fertiliser.** — Söderbaum, H. G., in *Kungl. Landtbruks Akademiens Handlingar och Tidskrift*, Year LVIII, No. 6, pp. 357-363. Linköping, 1919.

The author reviews the literature dealing with sulphur as a fertiliser and gives the results of his experiments. These were carried out with finely ground stick sulphur, using 16 glass jars containing 24 kg. of soil, growing oats from May 5 to August 11, 1919. The jars were divided into 4 series of 4 jars. The following yields were obtained :

	Crop			Weight of 1000 grains	Ratio Straw : Grain
	Total	Grain	Straw		
	gm.	gm.	gm.	gm.	
Series I (without sulphur)	60.2	26.3	33.9	34.2	1.288
» II (1 gm. of sulphur per jar)	62.1	26.4	35.7	36.5	1.352
» III (2 gm. per jar)	59.2	24.9	34.3	35.6	1.377
» IV (5 gm. » »)	62.4	27.6	34.8	36.1	1.260

The greatest differences found do not amount to double the probable error, whilst, in order to obtain safe data, they should be treble, without considering that the differences are not all of the same sign.

501 – **Papilionaceae in the Mostaganem Sands, Algeria.** — MANQUENÉ, J., in the *Bulletin de la Société d'Histoire Naturelle de l'Afrique du Nord*, Vol. X, No. 3, pp. 66-69. Algiers, March 15, 1919.

The various researches on the root nodules of leguminous plants have led to the general conclusion that root nodules are to be found mainly on Leguminoseae growing in poor soils.

There are exceptions to this rule, as the author found in the environment in which he has investigated the Papilionaceae for four years. This is the case with particularly poor sands that have been formed from astien gritstones (upper Pliocene) and which occur on the Mostaganem littoral.

From his researches he has deduced the following conclusions:

1) Papilionaceae growing in *poor, dry*, sandy soils, have no root nodules ; those of *rich soils*, whether wild or cultivated, bear root nodules.

2) Bacterial symbiosis may occur in poor soils if there is sufficient moisture. However, under these conditions many Paplionaceae still have no root nodules.

3) Moisture favours nodule formation to the greatest degree. *Very dry* soils, no matter what their physical or chemical composition may be, are unsuitable for the growth of nodules on Papilionaceae.

4) In general, no nodules are formed on a papilionaceous plant growing under unfavourable conditions of nutrition.

5) The structure of the root influences the intervention of the bacteria, for nodules are always most numerous on roots with well developed cortical layers.

6) The presence of root nodules is apparently related to the area of the aerial assimilating surfaces of the plant.

7) Nitrate of soda does not prevent nodule formation in the Papilionaceae (*Faba, Cicer, Trifolium*);

502 – **Contribution to the Study of the Immediate Composition of Maize Seeds.** — PASSERINI, N., in the *Bollettino della Società italiana per lo studio dell'alimentazione*, Vol. I, Nos. 1-3, pp. 17-30, Florence, 1919.

Large numbers of analyses of maize seeds have been made. Some workers say they are very rich in total nitrogen, as for example PASQUALINI, who found as much as 11.6 % of nitrogenous matter in Italian maize, BOUSSINGAULT, who found 12.8 %, and PORTELE, who found 14.2 % in the "Cinquantain de Hongrie". But most analyses show a much lower content of from 7 to 11 % in seeds containing 12 to 14 % of water.

A fresh series of analyses was carried out by the author on Italian and American maize ; the results, shown in the appended table, prove that maize is one of the poorest food cereals as regards protein content, as the total nitrogen content varied between 0.979 and 2.120 %,

with an average of 1.606 %. The maximum percentage was contained by an American maize specially selected for increased nitrogen content. When grown at Fauglia (province of Pisa, Italy), this maize retained, at least during 2 consecutive years, a higher nitrogen content than any of the other samples analysed; thus the percentage underwent a decrease that was greater in the first year of reproduction in Italy than in the second.

Amongst maize varieties rich in nitrogen, the author mentions *Zea rostrata* or toothed maize which, when grown in Italy, contains 2.088 % of total nitrogen.

	Nitrogen soluble in alcohol

Averages obtained on including the results of 16 previous analyses .	—	13.281	—	4.556	61.698	—	—	—	—	1.292	—	—	—	—

On calculating the average when including the data from 16 other analyses carried out by the author (*Atti della R. Accademia dei Georgofili* Series V, Vol. XI, 1914, the total nitrogen works out at 1.292 %. The nitrogen of the crude zein (soluble in alcohol) represents on an average about two fifths of the total nitrogen though it is almost half in some samples.

On screening, whole maize flour separates into fine flour, semolina, and bran consisting of the remains of the husk. The semolina contains the highest percentage of crude zein, as is shown in the adjoining table :

503 – **On the Composition of Sorghum.** — Willaman, J. J., West, R. M., Spriestersbach, D. O. and Holm, G. E., in the *Journal of Agricultural Research*, Vol. XVIII, No. 1, pp. 1-31, 18 diagrams, bibliography of 22 publications. Washington, October 1, 1919.

In 1877, the U. S. Department of Agriculture undertook a study of sorghum (*Sorghum vulgare*) as a sugar plant. Since then thousands of analyses of the juice of different varieties of sorghum have been made and published. Thus, well defined knowledge is available on the qualities and quantities of sugar present in sorghum juice, particularly in the sorghums grown in the temperate zone of the United States. In some papers, the effect of heading on the composition of the juice has been studied, while in others studies have been made of the technique of the preparation of sorghum syrup. But when Mr. West (one of the authors) began to give a better economic and scientific basis to the sorghum sugar industry in Minnesota in 1912, the need for further research became apparent : as regards the effect of climatic factors on the composition of the cane, more exact knowledge was needed concerning the behaviour of sorghum brought to the north in the most northerly limits of its zone ; 2) in order to lengthen the crushing season as much as possible, the cane ought to be used just before it is ripe and quite often after the death of canes killed by frost ; 3) the methods of purification and evaporation commonly used needed improvement and standardisation ; 4) for economic reasons, the small sorghum sugar works, with inefficient mills, where little or no purification took place and where evaporation was slow, should be replaced by the large mill, otherwise the fall observed in the production of sorghum syrup during the last 30 years would continue. Data of practical as well of scientific interest have been obtained by researches on this subject at the Minnesota Agricultural Experiment Station. The latter have been collected in *Bulletin* 187 of that Station, whilst the former are summarised in this abstract.

Three varieties of sorghum — Minnesota Early Amber, Early Rose, Dakota Amber — were chosen in order to study the progressive growth of the plant and the chemical composition of its different parts.

During one season, a determination was made of the relative proportion of weight of leaves, panicles and stripped cane in the freshly cut plant and in the partially dried plant. In the whole plant, the dry matter was continually on the increase up to maturity. The content of crude fibre decreases in a proportion practically equal to that of the increase of soluble carbohydrates, and the percentage of crude fat, ash and protein

remains practically constant for all the periods of growth observed. When the total quantities of each constituent present in the plant at the different period of growth are calculated, it can be seen that the plant builds up its cell structure of cellulose, protein and mineral matter during the first part of its growth period, and that the subsequent periods of growth consist in the filling up of these tissues by carbohydrates (starch in the seeds and sugar in the stems). No data were found that tended to show that the leaves give up their carbohydrates to the stem. The food value of the leaves is greater the older the plant.

The maturation of the panicles consists almost entirely in the filling up of a skeleton of cellulose and protein by starch. There is a considerable accumulation of mineral matter in the leaves, probably due to lime and silica. When an equal volume of alcohol is added to the juice expressed from the canes, a precipitate is obtained consisting of three parts: — 1) proteins; suspended cellular matter derived from the crushing of the fibre in the mills; 3) true gums: the gums are masses of galactanes and pentosans with about 20 % of mineral matter, especially lime magnesia and potash. The organic acids found in sorghum are aconitic, malic, citric, tartaric and oxalic acids.

The amido-nitrogen is present in high proportions in the juice of sorghum as well as in the ripe cane. This constitutes an important factor amongst the causes of difficulty of purifying sorghum juice for the production of syrup or sugar. The following nitrogenous substances have been found in sorghum juice: — l-leucine; d-l-asparagine; glutamine; cystine (?); aspartic acid.

The juice of the secondary stems is similar in composition to that of juice from the main stem during the same period of ripening. However, the maturation of the secondary stems is usually 3 weeks later than that of the main stem. The middle nodes of the stem, compared with the upper and lower nodes, contain more saccharose and total sugar, but less dextrose and laevulose. The upper nodes contain so little sugar and their juice has such an extremely low coefficient of purity that it is advisable to exclude them from the crushing when preparing syrup.

The stems of sorghum growing in Minnesota contain a much lower percentage of sugar than that in sorghum growing in regions with a longer and warmer growth period. Several observations make it probable that if the onset of frost could be retarded, the proportion of saccharose and reducing sugars in sorghums usually considered to be ripe would rise during 7 or 10 days and a larger quantity of total sugars would be elaborated. The juice of sorghums growing in the northern zone is of greater purity than the juice of sorghums growing in the southern zone. It is a phenomenon of precocious ripening that shows in most plants grown under suboptimum conditions: at the period when the panicle first appears, the reducing sugars are in excess over the saccharose. Afterwards the reducing sugars rapidly decrease, while the saccharose increases until the moment when in the period of complete flowering, they are present in almost equal

quantities. The respective changes continue until maturity is reached. At this moment, the ratio between saccharose and reducing sugars is about 70 : 30 in sorghum grown in Minnesota. In very ripe sorghum from Virginia, the ratio is 90 : 10 and even higher. The removal of the panicles before maturity of the seeds hastens on the production of the maximum of sugar in the juice, but this maximum would be reached later on without heading the plants.

504 – **The Essence of Mustard in Plants.** — CAUDA, A., in *Le Stazioni sperimentali agrarie italiane*, vol. LII, parts. 10-21, pp. 544-548. Modena, 1919.

Mustard essence (allyl iso-sulpho cyanide) is contained not only in various species of *Sinapio*, but also in numbers of other species — for example : *Cheiranthius Cheiri* — *Lepidium Draba* — *Bassica Napus* — *Raphanus Raphanistrum* — *Sisymbrium Alliaria* — *Nasturtium officinale* — *Lepidum sativum* — *Cochlearia Armoracia* — *Reseda lutea* — *Reseda luteola* — *Capparis spinosa* — various species of *Acacia* — *Thlaspi arvense* — *Asparagus officinale* — and various species of *Erysimum*.

Work carried out by the author shows that in a general way, seeds from southern climates have a lower percentage of essence content than seeds from a northern climate. This confirms the statement that the quantity is greatest where vegetation is less developed. This fact is due to the incomplete transformation of the chief plant albuminoids, which are not entirely assimilated and remain as reserve matter in the vegetable tissues.

The samples of mustard from Piemonte and Forlí with very small seeds (perhaps wild) contain on the whole a larger quantity of essence thant the samples of seed from other districts, for example Sicily, where this plan is cultivated in the ordinary way. It appears then that cultivation favours plant development, but decreases the essence content. An intimate relation exists between the essence content and the percentage of fats ; if the percentage is raised the essence content is lowered. Mustard seed from plants cultivated in warm climates are richer in oil but poorer in essence content.

Mustard oil is found in varying proportions but always fairly high : *Sinapis alba* 33 % — *S. nigra* 25 % — *S. arvensis* 30 %. This percentage varies according to the climatic conditions : *Brassica juncea* of Eritrea contains 40 % oil, and the Indian mustards 47.21 %.

The principal active enzyme of the Crucifereae is contained in special cells, very refractive to light, and exposed to view by the MILLON reagent — cells which HEINRICHER, through erroneous interpretation called " Eiweisschläuche " or albumin reserves. By means of different preparations of leaves or seeds, the author has traced the presence of such cells, and their number and size tend to diminish in the case of etiolated leaves.

According to NAEGELI (*Theorie der Gärung* p. 14) during seed germination, the potassium myronate splits up with the formation of mustard essence. By analyses of seeds and young green shoots, and etiolated shoots, the author states that the quantity of essence remains almost constant during the germinating period, but considerably decreases in the case of

young etiolated shoots. In seeds of Black Mustard (Salemi) : about 0.294 % was found; in young green shoots (air-dried) 0,280 %; in young etiolated shoots (air-dried) 0,170 %.

505 – **The Effect of Nitrogen Fixing Organisms and Nucleic Acid Derivatives on Plant Growth.** — BOTTOMLEY., W. B., in the *Proceedings of the Royal Society*. Serie B. Vol. 91, No. *B*-636. Biological Science, p'. 83 to 95. London, Jan. 1, 1920.

In a previous communication (*Proceedings of the Royal Society* Series B. Vol. LXXXIX, pp. 481-507, 1917) it has been shown by the author that a water extract of bacterised peat has a remarkable effect on the growth of *Lemna minor* in water culture solution, and that wheat seedlings when deprived of their endosperm at a very early stage, will not grow naturally unless supplied with a small quantity of organic matter.

A growth of *Azotobacter chroococcum* was obtained sterilised, and then transferred to a beaker with some distilled water, and heated on a water bath, when cold DETMER'S solution and distilled water were added to make up the required volume for use with *Lemna minor*. After 6 weeks, it was evident that the addition of the sterilised *Azotobacter chroococcum* to the culture solution, not only resulted in an increased rate of multiplication of the *Lemna* plants, but also enabled them to increase their original size, while the weight of control plants showed a corresponding decrease. Similar results were obtained with *Bacillus radicicola*. Extracts known as "crude nucleic acid derivatives from raw peat", and "adenine-uracil dinucleotide from raw peat" both had a similar effect on development.

When the extract of "crude nucleic acid derivatives were administered to the same plants and at the same time as the growths of *Azotobacter chroococcum*, the combined growth promoting effect was far greater than the sum of their effects when added separately. This shows that the stimulating constituents in the extract of bacterised peat differs from those in *A. chroococcum* Neither the ash of the nucleic acid derivatives nor the *A. chroococcum* had the slightest effect on growth. and the beneficial results following the addition of these materials can only be attributed to the organic constituents.

PLANT BREEDING

506 – **Possibility of an Intranuclear Cross in Homozygotes.** — LOISY. J. P., in *Genetica Nederlandsch Tijdschrift voor Erfelijkheids en Afstammingsleer*, Vol. I, Part I, pp. 92-97. La Haye, Jan. 1919.

As a result of the studies by MORGAN, it is a recognised fact that even in the nuclei haploids, chromosomes may be present in various forms and dimensions, which make crossing possible (between chromosomes) even in homozygotes.

This cross cannot take place during the synapsis phase. In a homozygote, with 3 different chromosome types, the synapsis appears as shown in Fig. I. The small black, white and shaded discs represent the chromatomeres the constituent of various chromosomes. One haploid has 18 chromatomeres and another, 36.

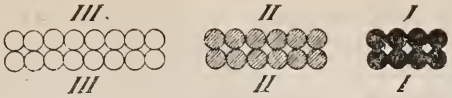

Fig. 1.

Although, in consequence of the division by reduction, the changes between the two homologous chromosomes may be possible, the nuclei gametes will always remain necessarily identical.

The crossing of chromosomes is not then possible during the synapsis period, but it can take place during the spiral phase when the chromosomes unite end to end and make a single line or a small crown composed simply of chromatomeres (fig. 2).

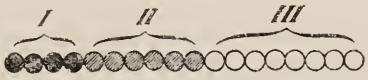

Fig. 2.

Usually, in the following phase, when the chromatomeres acquire their new individuality, the division of the elements rights itself at the points of union in such a way that their constitution remains unaltered (fig. 3).

Fig. 3.

This is the general rule. Let us suppose besides, that a chrome from chromosome II may fuse with chromosome V; let us suppose still further, that the division, instead of taking place at the points of contact, is displaced slightly toward chromosome II; in this case we should have an arrangement as in fig. 4.

Fig. 4.

Chromosome I with a chromatomere from chromosome II becomes chromosome IV. Chromosome II in its turn, becomes chromosome V with 4 chromatomeres only, instead of 5, whilst chromosome III although unaltered, will become in time, owing to its symmetry, chromosome VI.

Let us suppose now that a gamete, with chromosomes I. II, III, IV, V

and VI, may become united to a normal gamete with chromosomes I, II and III. An individual would be obtained which according to the arrangement of the chromosomes, is a hybrid, but, which, in possession regularly of 36 chromes, would not be easily distinguishable from the corresponding and absolutely normal homozygote represented in Fig. I. If should however be considered as a homozygote in the zygotes from which, at the moment of synapsis it will be changed into as many pairs of chromosomes as under normal conditions, but from which the following 8 gametes will be obtained:

I, II, III	I, II, VI	I, V, III	I, V, VI
IV, V, VI	IV, V, III	IV, II, VI	IV, II, III

Amongst these 8 gametes, the gametes I, II III and IV, V, VI are identical to those from which the individual is derived.

The gamete formed by chromosomes III and VI is identical to that formed by chromosomes III and III, being given that VI = III.

The gamete with chromosomes IV. V and III is identical to that which is constituted by chromosomes IV. V and VI, being given that III = IV.

The gamete with chromosomes I. V and III is identical to the gamete with chromosomes I. V and VI, being given that III = IV.

The gamete with chromosomes IV. II and VI will be identical to the chromosomes IV. II and III, being given always that VI = III.

There are therefore now only 3 gametes to consider: I. V. III and IV. III. VI — The former possesses a lower chromatomere (= 17) (fig. 5) and the latter a higher chromatomere (= 19) (fig. 6).

Fig. 5.

Fig. 6.

By the fusion of 2 gametes, type I. V. VI, a loss mutant or "Verlustmutant" would be derived, and by the fusion of gametes; type IV. II. VI: a "progressive mutant", i. e. + the new chromatomeres.

What will happen when a cross is made between these mutants and the original:

Fig. 7.

In the case of the loss mutant, an individual would be obtained after uniting with the original, with a composition as shown in Fig. 7 and from this 8 gametes would originate.

A	with	chromosomes	I, II, III					
B	»	»	I, V, VI					
C	»	»	I, II, VI	=	A being	given	that VI	= III
D	»	»	I, V, III	=	B »	»	» III	= VI
E	»	»	I, V, III	=	B »	»	» III	= VI
F	»	»	I, II, VI	=	A »	»	» VI	= III
G	»	»	I, V, VI	=	B			
H	»	»	I, II, III	=	A			

Fig. 8. shows that 64 combinations are possible. Records of 16 AA ; 32 AB : 16 BB are given following the scheme 1 : 2 : 1 of a mendelian monohybrid. It can however be concluded that, by uniting a homozygote normal type gamete with a gamete which as a result of an exchange of elements between chromosomes, has lost a chrome, the phenomena of segregation of characters following the Mendelian scheme for a monohybrid, would be obtained in F^2.

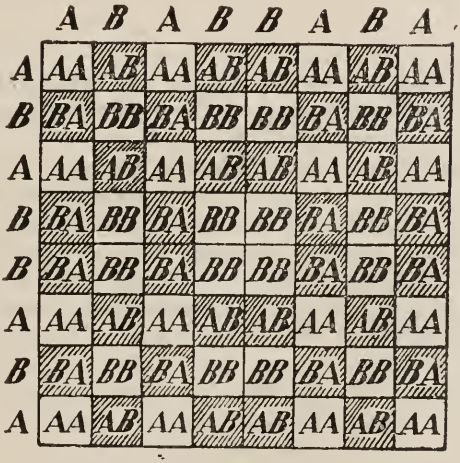

Fig. 8.

What will happen when a cross is made between a gamete of a progressive mutant and a gamete of a normal homozygote ? In the zygote from which the individual sprang, the synapsis will give pairs as indicated in Fig. 9. As in the preceding case, the two components can be distinguished only by one chromosome ; the pair I. V takes the place here of the pair II. V, but the result is always the same, with a segregation of characters in F_2, following the mendelian scheme of a monohybrid.

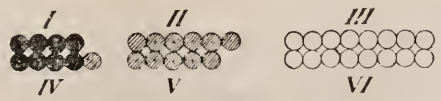

Fig. 9.

The progressive mutant studied by the author differs from the progressive mutant (DE VRIES) only because here the formation of a new determinative is not stated, but the simple halving of a chromatomere.

In any case, it is obvious that by a "cross between chromosomes" even in homozygotes, can originate from mutation loss and even from forms which do not differ from DE VRIES progressive mutants. It can be concluded that *all the "mutations" met with in pure lines can be explained by the phenomena of the cross between chromosomes".*

This is naturally only the case with sexual reproduction. Considering two plants which reproduce asexually, the exchange of elements between chromosomes is possible even in the haploid. The total number of chromosomes remains, however, unaltered under all circumstances, and the production of mutants is not possible.

In order to obtain the latter, a further cross between the gametes is necessary. Therefore : *for the formation of the "mutant" not only a cross between chromosomes is necessary, but also a successive cross between individuals.*

507 - **Improvement of Ligowo Oats by Crossing with Brie Oats and by Selection.** — SCHRIBAUX, in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. VI, No. 6, pp. 113-122. Paris, 11 Feb. 1920.

The authors' object is to publish the names of the four new varieties of oats with high yields, obtained at the Experimental Seed Station, by crossing the black Brie oat with the white Ligowo oat.

The black Brie oat belongs to a type of oats of high quality. In this variety, not only the glumes are fine, but they open more or less readily when thrashed. As a result of the quality of the husk, the grain which would have been swallowed without mastication, instead becomes easily impregnated with digestive sugars, favourable to digestion.

The Brie oat, an essentially French variety, possesses an exceptional adaptability to the climate in the North of France.

On the other hand, there are obvious disadvantages :

(2) it is a late cropper, which means it is exposed to heat during particularly dry seasons.

(3) it is loose glumed ; it is necessary therefore to crop when still green in order not to loss the finest grains.

The *Ligowo oat* is probably the most widely cultivated variety to-day in the intensive culture district ; it should be mentioned that its popularity somewhat diminished after the introduction of Victoire (Seger) and Pluie d'Or of Svalöf.

If the Brie oat is the type notable for quality, the white Ligowo oat is the type notable for quantity. The latter shows also :

(1) resistance to lodging ; (2) a tendency to early cropping which ensures success in almost all localities on rich or medium soils, as much in Central France as in the North (if sown in the autumn) ; the suppleness of temperament ensures regular cropping from year to year.

Objections to the Ligowo variety are raised owing to its brittle straw

and thick and hard glumes which completely envelop the caryopses in such a way that the grains pass into the excrements of old horses with defective mastication. The glume percentage under ordinary conditions oscillates round 28% ; and for the Brie oats, round 23%. The food value of the skin being very weak, compared to that of the caryopsis, it can be admitted without much error, that at equal rates, Ligowo should cost 5 to 7 % less than " Brie ". The reduction in cost of Ligowo should lie chiefly with freshly crushed grain, in order to ensure complete caryopsis assimilation.

The preceding remarks show that Brie and Ligowo possess altogether different properties. If their qualities were united, an almost perfect oat would be obtained. It was for the season that the Station undertook work in connection with the crossing of the two varieties. The author hastens to add that no direct result has yet been reached.

The following is the schedule of the faults and qualities of the Ligowo × Brie oat.

Glumes and Awns. — The chief fault with the hybrids lies with the production of grains similar to Ligowo grains with thick skins, and with awns, the awns make them less attractive, as they have only been partly picked off by thrashing ; they decrease the weight of the hectolitre. They can be of inconvenience when oats are sown by the drill machine.

A yearly variable proportion of double grains has been discovered, the first completely sterile at the base enveloping the second.

Table I shows the glume percentage of the hybrids and their descendants and also in the following Tables, the author includes Victoire de Svalöf. The present reputation which this excellent variety has acquired in France, and elsewhere, encouraged comparative tests to be made.

TABLE I. — " *Glumes* ".

A — EXPERIMENTS 1915.

Brie	23,35%	Hybrids	Ligowo × Brie	N° 9	26.11%

					N° 186	26.80

B. — EXPERIMENTS 1919 (refined grain).

Brie	21,70%	Hybrids	Ligowo × Brie	N° 9	24.10%
Ligowo		»	»	»	N° 27	28.80
Victoire	27,20	»	»	»	N° 176	26.80
					N° 180	23.20

27 and 176 very nearly contain the same proportions as Ligowo ; 9 and 186, slightly weaker proportions. It has already been noted that is advisable to crush Ligowo in order to increase digestibility ; the hybrids should be treated in the same way.

Straw. — The very dry summer of 1919 allowed the author to make observations as to the relative turgidity of the chaff of Ligowo, and Victoire and the hybrids. The yield was as yet only limited, and the Ligowo straw and Victoire straw broke like glass when cut in dry weather. In the hybrids, the proportion of straw broken was three or four times less, as shown by the figures in Table II.

TABLE II. — *Relative turgidity of stubble. — Experiments in* 1915. *Percentages of stubble broken in cropping.*

Ligowo parent . . .	40%	Hybrid Ligowo × Brie N° 9	15%
Ligowo di Swalöf. .	43%	» » » N° 27	11
Victoire	47	» » » N° 176	15
		N° 186	—

Maturity. — The hybrids are less forward in thus respect than Ligowo and Victoire.

TABLE III. — *Relative maturity.*

	Date of earing	
	1915	1919
Brie	2 July	29 June
Ligowo	30 June	25 June
Victoire	30 June	24 June
Hybrid Ligowo × Brie N° 9	29 June	20 June
» » » N° 27	30 June	21 June
» » » N° 176	2 July	23 June
» » » N° 186	2 July	23 June

Resistance to lodging. — The most outstanding positive character of the hybrid Ligowo × Brie is without doubt, the solidity and elasticity of the stubble and the resistance to lodging. This is far superior to that of Ligowo and even to Seger.

Yield. — The following Table gives the comparative yields of Victoire and the hybrids, representing the Ligowo yields per 100.

	Noisy (1915)	Grignon (1919)
Ligowo	100	100
Victoire	114,6	—
Ligowo × Brie N° 9	110,6	124
» » N° 27	135,20	114
» » N° 176	130	109
» » N° 186	118	116

The hybrids distinctly showed higher yields than Ligowo in both series of experiments.

Resistance to falling off and shelling of grains. — With the Ligowo and Victoire varieties it is not unusual for a certain number of inflorescences at the base of the panicle to fail to ripen, and to drop :

With the hybrids Ligowo × Brie, this is very unusual and in every case, much less marked than with the others. The 'shelling' is also less feared than with Ligowo and Victoire.

Tillering. — The tillering capacity of hybrids is weak, especially compared with the varieties Brie and Grise de Houdon. It is necessary to sow thickly.

Conclusions. — The hybrids Ligowo × Brie, black like the Brie variety, have not inherited the fineness in grain. They can be defined as Improved Black Ligowos. Before the war, the blackness might have been an attraction, at least in the neighbourhood of Paris, but the more advantageous characteristics recommend themselves to the attention of cultivators.

At the trial experiments carried out at Noisy and Grignon, they all showed up superior to Ligowo and three (Nos. 27, 176 and 86) to Victoire in the following ways :

(1) increase in yield ;

(2) stronger resistance to lodging to falling, off and to shelling ;

(3) more turgidity of straw — during the cropping period, and matured very early, and in very dry weather.

The hybrids possess too, a tendency to early maturity equal to or slighty superior to that of Ligowo and Victoire which suggests the idea that they would accomodate themselves in the same way to quite different conditions of soil and climate.

As they are very productive, it stands to reason, that it is on rich and well cultivated soil that their good qualities show up to the fullest extent ; their feeble tillering capacity demands thick sowing, in order to obtain sufficient stock and to avoid scorching.

These conclusions are drawn from the author's experiments on small areas. How would these hybrids behave cultivated on a large scale ? What is the opinion of farmers who have carried out experiments for the last 4 years ? The author intends to reply to these questions later.

508 – **Heritable Characters of the Maize. "Lineate leaves.** — Collins, G. N. and Kampton, J. H. in *The Journal of Heredity*, Vol. XI, No. 1, pp. 2-6 + 1 pl. Washington, Jan. 1920.

This article is the first of a series in which the authors propose to describe and illustrate the heritable variations of maize as they arise or are discovered.

Abnormalities in maize are of such frequent occurrence that it would be impracticable and probably even undesirable to attempt to describe individual variations. But, as soon as it has been demonstrated that a new character is inherited, and that a stock of seed capable of reproducing the character has been secured, it is desirable to have the variations brought

to the attention of other workers. This will save double work, and variations are less likely to be overlooked.

Our knowledge of the interrelation of Mendelian characters should proceed with increasing rapidity as the number of such characters increases.

If the linear arrangement of characters in inheritance should be found to hold for maize as for *Drosophila*, the proper location of a new character becomes easier as the number of characters whose location is known increases.

Although the majority of the heritable differences in maize are of such a complete nature as to make Mendelian analyses difficult or impossible, alternative characters are coming to light in such numbers as to warrant the belief that maize will rival *Drosophila* as material for the investigation of the linear arrangement of factors and of chromosomes.

From the scientific point of view, a knowledge of the variations latent is of great economic importance, since most of the variant forms are less productive than the normal forms and must be carefully investigated, to be eliminated.

The character here described and designated as "lineate leaves" consists of a number of very fine white stripings on the blades of the upper leaves.

The stripes are usually from $^1/_{10}$ to $^1/_4$ mm., in width and vary from a few millimetres to many centimetres in length, and are very close together. The general effect of the closely spaced stripes gives the blade a grayish appearance that contrasts sharply with the uniform green of normal leaves.

"Lineate leaves" were first observed at Lanham Maryland in 1918, amongst the hybrids between Stowell's Evergreen, and a prolific variety from Brownsville Texas.

The original cross was made in 1912. In 1913, the F_1 population was grown in an isolated block at Victoria, Texas. In 1914, an F_2 population was grown at Lanham, and from the crossing for the two plants, the ear designated Ph 124 was secured.

Plants from Ph 124 were grown in Chula Vista (California) in 1915, and 1916 again in Lanham (Maryland) when one cross pollinated ear Ph. 124 LI was secured. In 1917 seeds of Ph. 124 were again sown, together with seeds of Ph. 124 LI. From these souwings there were secured 16 cross pollinated ears of Ph. 124,31 cross pollinated ears of Ph 124 LI, and 8 crosses between Ph. 124 and Ph. 124 LI.

In 1918, the 16 cross pollinated ears of the Ph 124 progeny and 3 of the crosses Ph. 124 × Ph 124 LI, were planted. Lineate leaves occurred in 3 of the 16 progenies of Ph. 124, and in one of the crosses between Ph. 124 and Ph. 124 LI.

The adjoining Table shows the ratio of normal green plants to lineate plants.

Number of Lineate and Number of Green Plants in four Progeny grown from hand-pollinated ears.

Progeny destination	No. of green plants	No. of lineate plants	Ratio green : lineate
Ph 124 I, 2	15	7	16.5 : 5.5
Ph 124 I, 3	20	11	23.3 : 7.7
Ph 124 I, 5	18	6	18.0 : 6.0
Ph 124 I, 10.	24	8	24.0 : 8.0
Total	77	32	82 : 27

The ratios are all reasonably close to the monohybrid 3 : 1. The results may be explained by assuming that one parent of Ph. 124 was heterozygous for lineate, a simple Mendelian character recessive to the normal green.

509 – **Pedigree Selection of the Local Variety of Rice "Phung-tien" in Indo-China.** — CARLE, E., in the *Bulletin agricole de l'Institut Scientifique de Saïgon*, Vol. II, No. 1, pp. 26-32. Saigon, Jan. 1920.

The author gives first the characteristics of the local variety "Phung-tien" with instructive comparisons of the results obtained by tracing selection pedigree. These characteristics are as follows :

Source	Bentré
Date	1911
Colour of bran	yellow
Shape of grain	slightly elongated
Weight of 1000 grains	29.429 gm.
Percentage + red husk	0.46 »
Total percentage of husks	80.04 »
Percentage of bran	19.96 »
Yield per hectare	1500 to 2200 kg.
Period	6 months

SELECTION. — At the Phu-my Experimental Station 1915-1916, the seed and selection origen of 100 plants were marked and numbered when mature (*Elites Vilmorin*). These were cropped separately, then underwent investigation in the Laboratory and were weighed successively with a view to their registration on a special Table.

Numbered according to each individual species or line, the 5 best have been picked out, from the 100 mentioned after examination of the data given as a result of this experiment (1915-1917).

1st *Generation.* — In 1916 and 1917 at Phu-my several hundred plants for each line were grown, and each group derived from one single seed.

2nd *and* 3rd *Generations.* — These experiments were conducted in 1917 and 1918 in the same Station, but on different plots for each new genera-

tion ; in this case also, several hundred individual plants were under investigation.

The statistics registered for these 4 generations are shown in the following Table.

No. of line	No. of ears per 100 plants	Weight of ears in kg.	Average weight of one ear in gm.
	1st. Generation		
365	845	1 551	1.83
348	702	1 441	2.05
329	779	1 432	1.13
359	588	1 322	2.24
379	674	1 281	1.90
	2nd. Generation		
365	560	1 456	2.60
348	586	1 554	2.65
329	582	1 754	3.00
359	625	1 570	2.50
379	621	2 053	3.30
	3rd. Generation		
365	641	1 600	2.45
348	893	1 709	2.00
329	770	2 102	7.73
359	660	1 911	4.00
379	858	2 373	2.70

These figures give an idea of the comparative value of each line and furnish a market criterion of choice.

CULTURAL COMPARATIVE TESTS ON ORIGIN " POPULATIONS ". — Cultures made with ordinary seed, picked out and sorted (MAROT and the CERTANI method) show that from 1916 to 1917 and 1917 to 1918, the yields varied from 1400 to 2400 kg. per hectare Compared with this, from 1918 to 1919, a sufficiently extensive plot was used to sow seeds from a mixture of several selected lines of the 2nd generation ; the yields obtained were good, from 2,300 kg., the yield rose to 3489 kg. per hectare.

The important comparative cultural operations are still in progress not only at Saigon, but also at Tanan.

The pure line cultures have been conducted this year in such a way that the results from February to March 1920 are now on record.

HOMOGENEITY. — One of the most striking and advantageous characteristics of the pure lines relative to the common varieties is the homegeneity and uniformity of the cultures. The differences in the number of heads in each group and between the weights of the spikes on

the same plant are considerably lessened as a result of the selection whilst at the same time the produce increases.

Similar uniformity is encountered with regard to tillering, height, vigour of growth, inflorescence and maturity. The variation in the date of flowering, in the case of one line raised from another is up to 15 days; whilst for individual plants of the same line, there is a perfect correspondance in date.

General conclusions. — The different observations made from the experiments, and which were taken from a certain number of local varieties are as follows:

(1) Homogeneity and uniformity.

(2) The obtaining of an optimum tilth varying with each variety for the same place: at Phu-my the optimum is from 5 to 9 ears per group; variety Ra-may; for other varieties, this optimum varies, but does not exceed 12.

(3) It is from the 3rd or 4th generations that the lines give the maximum yields.

(4) The average weight of the head improves according to selection pedigree, and this is maintained after the 2nd generation.

(5) The average weight of the seed increases and remains high compared with the average weight of the seed from the original.

510 - **Improvement of Rice by Selection and Hybridisation in Java.** — Viellard, P., in *Bulletin agricole de l'Institut scientifique de Saigon*, Year II, No. 1, pp. 11-15. Saigon, Jan. 1920.

The methods of selection employed at Buitenzorg on the same lines as those employed at Svalöf for the cereals in Northern Europe are based on the following facts, in accordance with botanical and genetical theories held by a large number of specialists:

(1) The cultivated varieties of rice (these should not be confused with botanical varieties) include a considerable number of fixed strains, similar to those known in the botanical world under the name of "subspecies" or "Jordan species".

(2) Each of these strains differs from the surrounding types of the same variety in characters of neglible importance morphologically, but which mean a great deal from the cultural standpoint, (*e. g.*: yield, early maturity, resistance to disease, etc.). These distinctive characters are admittedly entirely transmissible to progeny.

(3) Compared with the habit of several other cereals, self-pollination is the usual habit with rice, and cross-pollination is very rare. This certainly facilitates to a large extent the process of selection, as it permits close spacing, and of several pure lines coming from the same or different varieties, without running the risk of undesirable crosses.

It is easy to see, therefore, that if a cultural variety is selected which shows a combination of good characters (weight of yield, quality of grain, resistance to disease), or which possesses one of these points to a marked extent, it will be sufficient to multiply a pure line to obtain several gene-

rations later, a new cultural variety following the natural course, but with the advantage of each individual possessing qualities of a select strain superior in one form or another to the original variety («population »).

The following is a brief survey of the method employed in Java at Tjikenmeuh.

The "population" rice is sown in the nursery according to the usual custom, and then pricked out on to an area of about 20 acres, with much care taken to avoid putting more than one plant into each hole. Throughout the growing period, the rice field is watched, and out of the 100,000 to 200,000 plants thus pricked out, about 300 select types are chosen.

The record of the yield of each plant is made separately. In the laboratory, the less interesting ones are eliminated, and about 75 to 80 in all, are conserved. These will form the origin of the pure line selection.

The following year, each of the 75 to 80 lines thus obtained is sown and repricked out, always at equal distances apart, on small plots (4.7 to 7 sq. yds.). Three plots at least, are reserved for each line and these are distributed in various quarters of the field, so as to avoid variations due to dissimilarity of soil. In the harvest season, the produce from all the plots is collected at the same time. In this way 75 to 80 crops are obtained, and these are investigated in the laboratory according to the characters it is desirable to retain.

The third year, work is not continued with the 10 to 15 best lines in the second selection, but this time the plots reserved for each line are multiplied as far as possible. The crops thereby obtained serve as a base for the definite choice of the type, or types, which will advantageously take the place of the original "population".

At Java, up to the present time, a dozen varieties have undergone this method of selection and have furnished twenty pure lines. These lines multiplied over large areas, for the last 2 or 3 years in control plots have shown homogeneity and fixed characters as expected. With regard to the yield, there was an average increase of 20 %.

It is noticeable, as predicted, that the results obtained showed a distinct improvement to the original and less homogenous population.

The Tjikenmeuh Station is assisted in plant breeding work by the co-operation of the "Jardins de semences" directed by M. VAN DER STOK, and the work extends over the centre and east of Java and to demonstration fields at the local agricultural schools. It is reasonable, therefore to hope that the results, already distinctly advantageous, will be accentuated and confirmed in the near future.

The author gives a brief survey of the hybridisation experiments made at Tjikenmeuh.

Artificial pollination of rice is a somewhat difficult operation which was for a long time considered impossible.

M. VAN DER STOCK, who was the first to succeed, has, however, never obtained more than a very minor degree of success. The local varieties,

crossed 7 years before and with progeny followed with great care up to the present time are "Skriviman Koti" and "Carolina". The first is a plant of very considerable vigour, leaves dark green, form erect. The yield is high but unfortunately the grain is of an inferior quality. The second variety, on the contrary, shows lack of vigour, the leaves are large, light green and drooping, but it makes up for this by producing grain, although in poor quantities, of the biggest and best quality obtainable in Java and perhaps even in the whole world. The flowering period is 3 weeks earlier than that of Skriviman Koti.

Hybrids are selected in each generation. F_7 under the authors' observation, gave more than 200 hybrids cultivated on plots of an average area of 7 sq. yd., and which showed a combination of characters of the 2 parents. In several cases "transgression" was noted.

Certain hybrids flowered 8 days earlier than Carolina (the variety which matures the quicker of the 2 parents). Others gave larger grain than Carolina. These facts are sufficiently encouraging to raise hopes, and the confirmation of the results obtained at Tjikeumeh will open up an efficient means of action to rice breeders for the improvement of local varieties, by crossing with superior imported varieties.

511 – **On Variation in Tartary Buckwheat, *Fagopyrum tataricum* (L.) Gaertn. in the United States.** — ZINN, JACOB, in the *Proceedings of the National Academy of Sciences*, Vol. 5, No. 11, pp. 506-514. Washington, Nov. 1919.

Results are shown of a series of experiments carried out by the author on *Fagopyrum tartaricum* Gaertn (*Polygonum tartaricum* Linn.). The high variation and transmission of the external characters made it first necessary to investigate the behaviour of this race under different conditions before attempting an analysis of the underlying genetic causes.

In a population of several hundreds of plants, one plant was found to be distinguished by a particularly high degree of variability in the structure of its flowers. This plant was selected as a starting point of a strict pedigree culture, and since its isolation, five generations have been grown, and involved an examination of more than 57,000 flowers and fruits.

The variations here considered, occur in the gynœceum, the perigone, and the vegetative organs.

The variations in the gynœceum are characterised by the production of supernumerary carpels, varying from 3 to 25 per pistil (instead of the usual 5). Under ordinary conditions of growth, the number of flowers with normal gynœcium predominates over or equals the number of flowers with abnormal gynœcium; the variation curve is consequently unilateral.

Under conditions favouring the development of abnormal flowers, the variation is bilateral, and is represented by a curve, the apex of which is formed by the abnormal 4-carpelled flowers. The percentage frequencies of a number of flowers with 3-4-5-6-7-8-9-10-11-12-13-14-16-18-19 carpels is — 17.98 — **67.73** — 7.79 — 1.71 — 0.64 — 0.86 — 0.49 — 0.75 — — 0.07 — 0.29 — 0.06 — 0.06 — 0.02 — 0.02 — 0.02 % respectively.

Associated with the abnormal gynœcium are abnormal perigones with

a number of segments ranging as high as 18. The variation always remains unilateral in the number of perigone leaves. The frequency of the normal, five parted perigones decreases as the number of carpels per pistil increases. The percentage frequencies of the number of flowers with respect to the number of perigone leaves, namely 5-6-7-8-9-10-11-12 is as follows **71.72** — 21.62 — 4-31 — 1.29 — 0.37 — 0.59 — 0.02 — 0.08 % respectively.

Between the number of carpels and the number of perigones leaves, there exists a distinct positive correlation.

All descendants of this race were found to reproduce the type of the mother plant regardless of whether they originated from normal or abnormal fruits of the parent. Conditions of temperature, moisture, and nutrition, considerably controlled the intensity of abnormal development.

Dimorphism manifests itself in two externally different forms ; similar to that found in the case of *Trifolium pratense quinquefolium* De Vries and *Veronica agrestis*.

512 – **Selection in Soy Beans in the Philippines.** — Noroña Maceda, Felix, in *The Philippine Agriculturist*, Vol. VIII, No. 3, pp. 92-98. Los Baños, Oct. 1919.

Layosa had already been engaged in work in connection with selection in soy beans, and the author in continuation of Layosa's theses has undertaken a series of experiments for the following purposes :

(1) The multiplication of strains selected by Layosa and the running of " plant-to-row " tests of the most productive individuals or elites of each strain ;

(2) The isolation of strains that can be recommended for the rainy season or for the dry season under local conditions ;

(3) The comparison of the yield of selected strains with that of unselected plants.

Elite cultures of Amis Beans (217 F_5) during the rainy season.

Pedigree number	Parents	Descendants		
	Computed yield per hectare	Computed yield per hectare	Computed gain or loss over parent	Computed gain over common stock
2 (N_7)	471.73	1192.8	721.1	880.4
3 (N_8)	426.27	1278.0	851 7	965.6
4 (N_9)	563.47	1107.6	544.1	795.2
5 (N_{10})	455.46	606.4	150.9	294.0
Common stock	239 99	312.4	—	—

As a result of favourable environmental and climatic conditions during 1918, the increase in yield from selected strains was obvious.

Similar results were obtained from the " plant-to-row " cultures, providing materials for subsequent multiplication. Each of the four

trains selected by LAYOSA gave in every case a higher yield in beans than their respective parents, at the rate of 55-79 % and more.

Multiplication cultures of Amis Bean (217 F_6 and F_7) during dry season.

Pedigree number	Parents	Progeny		
	Computed yield per ha.	Computed yield per ha.	Computed gain or loss over common stock	Percentage inc. of offspring over common stock
2 ($P_7 - N_1$)	202.66	511.2	277.8	54 %
2 ($P_7 - N_2$)	247.99	369.2	135.8	37
0 ($P_{80} - N_{17}$)	243.35	284.0	50.6	18
2 ($P_{80} - N_{12}$)	407.95	397.6	164.2	41
4 ($P_{80} - N_{21}$)	291.72	69.2	164.2	−237
0 ($P_{80} - N_5$)	557.07	340.0	106.6	− 31
6 ($P_{108} - N_{17}$)	730.67	284.0	50.6	18
9 ($P_{107} - N_7$)	766.93	340.8	107.4	31
6 ($P_{138} - N_{33}$)	191.19	142.0	− 91.4	− 64
7 ($P_{138} - N_{13}$)	535.55	369.2	135.8	36
8 ($P_{138} - N_{14}$)	751.46	482.4	149.0	31
Common stock	—	233.4	—	—

With two exceptions, all selected strains grown in this work, gave higher yields than the common stock, thus showing the advantage to be derived from selection. The gain in percentages of yield of the selected strains over the common sort ranges, in multiplication plantings from 18 % to 79 %.

513 – **Improvement of Sugar Beet by Selection, in France.** — GAILLOT, M., in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. V, No. 39, pp. 986-995. Paris, Dec. 1919.

The cultivation of sugar beet in the north of France is a subject of real interest : the rotation system is employed in conjunction with wheat production, and results in an entirely advantageous effect on meat value, as the stubble can be readily used for feeding purposes and for fattening livestock.

In addition to this, the sugar industry opens up in the same district commercial undertakings in all branches of national welfare, as, for example, agricultural machinery, industrial institutions, chemical fertilisers for which sugar beet is essential, chemical products, textures and all materials necessary for the equipment of sugar factories.

In spite of all this, the production of sugar beet in the north of France has a tendency to decrease and take a second place in relation to foreign competition.

Although to the outsider the richness of the sugar content in the roots,

and the yield per hectare has always been on the increase, with the result in the natural course of events that the cultivation is increasingly profitable to the agriculturist, this is not the case in France. Quite apart from the questions of climate, soil, manual labour, etc., so often raised, the fundamental cause of this inferiority may be attributed to the fact that, with regard to the production of seed, the French market is entirely dependant on the foreign market. Consequently two serious difficulties are involved :

(1) the agriculturists cannot depend on any profit which is undoubtedly connected with the production and sale of beet-seed ;

(2) the seed employed, even if guaranteed pure, comes inevitably from regions with a different climate and soil, and which, when taken to a new destination, may show some discrepancy, and this is often the case.

The author having insisted on the need of producing the necessary seed on native territory, following the German method, gives an account of the results of his own work of selection started in 1909.

For some years comparison cultivation trials were conducted with the French and foreign varieties considered to be the most adaptable to the various soils in the Soissonnais district. A comparison between the quality of the sugar and the weight of sugar produced per hectare on each type of soil, made it possible to discover the most suitable varieties. Amongst these, certain individual types were selected, distinguished by the development of characteristics which it was desired to stabilise, and these were reserved as parents for future generations and pure line selection.

To speak candidly, it is not a case of pure line selection in the true sense of the phrase. Apart from the ordinary course ; — when the parents are isolated, and self-pollination is necessitated, a mixed progeny is the result with the following predominating features : red beets with white skin and leaves green and red, fodder beets, green and white beets, beets with lanceolate leaves and forked roots, similar to the wild beet, and a small number of individuals comparable with the parent. Also, as is well known the sugar is obtained in successive stages from the fodder beet, and this in its turn is derived in a similar fashion from the wild beet. The isolation in this particular case, has the habit of encouraging atavism by the dissociation of the characters in the beet.

By enclosing two instead of one specimen under the same cover, or even in the open air, the number of good roots attached to the progeny increases, even if there is always a higher percentage of natural material due to self-pollination. It is sufficient if the two types do not flower simultaneously, to ensure self-pollination.

To avoid mishap, the author believes it necessary to have recourse to crossing parent stock, by collecting them is small groups of 4 to 7 and engendering a simultaneous flowering period by constant pinching of of buds. In order to obtain good results, it is important that the individuals as far as possible, possess the same characteristics. Their choice, however, will depend largely on a thorough investigation of the characters dur

the various phases in growth development up till the moment when the productive organs are developed.

The seeds thus obtained are taken from each plant and sown separately in plots, and the plants submitted to careful examination with respect to their botanic and physiological characters, such as :— late or early maturity, number of leaves, weight of root, sugar content and its quality, etc. The final choice is limited to types which transmit exactly similar characteristics to their progeny. These are reserved definitely as parent stock, and the seed sown the following year on plots devoted entirely to parent stock.

The beets collected from each plot undergo thorough examination in the field and in the laboratory. The chemical analysis is made both in cold and warm aqueous solutions, and the beets have been subdivided as follows : 1) " super-élites " — to serve as new parent stock ; 2) " élites " or grand-parents, to serve as the source of seed for commercial purposes.

The super-élites have naturally been studied with the minutest attention and a special record kept, following the GALTON curves method by which the percentage of beets showing equal proportion and equal quality in each family is signified. The plans, diagrams and illustrations, etc. make the comparison between the various progeny easy and effectual. As the beet is a perennial, it is hoped to maintain the production over super-élites as long as possible. It is certain that, in any case, the yield of seed decreases year by year, and it is the same with regard to the sugar content, which is 20-22 % before transplanting and then falls to 4-6 %. The author intends to keep a record of the value of the seeds thus collected for several years in succession, and compare these with the first year results.

The élites are also a subject of observation and of rigorous selection during the growing period. All the élites proceding from different families but belonging to the same order, are planted out close to each other, to enable ready crossing. The seed thus obtained is reserved for use to grow plants intended later to furnish seed for commercial purposes.

514 – **Variation of the Coconut tree observed in Ceylon.** — *The Tropical Agriculturist*, v. LIV, No. 1, p. 1. Peradeniya (Ceylon), January, 1920.

Some years ago, in the North Western Province, a coconut tree was noticed which bore yellow and green fruit at the same time. The main trunk showed longitudinal green and yellow stripes ; and the branches which sprang from the green stripes produced green fruits and those from the yellow stripes produced yellow fruit.

By sowing two nuts from the two different types, two young plants were obtained, one normal and green, the other of a yellow shade with the midrib of its leaves, yellow or bronze.

This case is interesting in that it indicates that yellow varieties of coconut could reasonably be obtained from the normal green type by following the variations of the shoots.

515 – **Probable Origin of the Dwarf Cocoanut Tree.** — See No. 524 in this *Bulletin*.

516 – **Fasciation and Dichotomy following the Grafting of two Portuguese Vines.** — José Duarte d'Oliveira, in *Comptes rendus de l'Académie des Sciences*, vol. CLXX, No. 10, p. 615-616. Paris, March, 8, 1920.

The variety Gonçalo Pires of Portuguese Vine grafted on *Riparia* × *Rupestris* 3309, and characterised by the development of fasciated branches, nearly always dichotomous, produced much fruit, but wine of only medium quality.

On this vine the author regrafted the variety "Albinio de Souza" (red) which produces a small crop but excellent wine and shows no signs of fasciation or dichotomy.

Grafting was done in March 1919. In June it was noticed that the shoots of the scion Albinio de Souza were fasciated and dichotomous just like the stock Gonçalo Pires; the scion continued to grow in exactly the same way as this stock.

This then is a case of transmission of two specific characters from stock to scion.

517 – **Illustration of the Definite Principles of Heredity Hybrid *Catalpa : Catalpa bignonoides* × *C. Kaempferi*.** — Jones D. F. and Filley W. O. in *The Journal of Heredity*, v. XI, No 1, pp. 16-24 + 9 figs. Washington, Jan. 1920.

The result of a series of experiments with the hybrids *Catalpa bignonoides* × *C. Kaempferi*. The cross was made by emasculating the flowers of *C. bignonoides*, enclosing them in bags, and later applying pollen of *C. Kaempferi* by hand.

Comparison of the First Generation Hybrid of *C. bignonoides* by *C. Kaempferi* with its Two Parents Species

		C. bignonoides	*C. bignonoides* ♀ × *C. Kaempferi* ♂	*C. Kaempferi*
Bark		Rough	Smooth	Smooth
Leaf-upper surface		Glabrous	Pubescent	Pubescent
» lower surface		Hirsute	Sparingly hirsute on young leaves	Glabrous
» shape		Generally ovate	Generally cordate	Generally cordate
» margin		Entire	Three lobed rarely entire	Three lobed rarely entire
Petiole		Slightly coloured on young leaves	Coloured	Deeply coloured
Insertion of petiole		Not coloured	Not coloured	Coloured
Flower - colour		White with brownish purplish spots and orange stripes.	White with brownish purplish spots and orange stripes	Pale yellow with brownish purplish spots a dark yellow stripes
Pods	length	3 to 3.5 cm	3 to 3.5 cm	2 cm
	breadth	3 to 3.5 cm	2 to 2.5-3 cm	2 cm
	length	30 to 35 cm	20 to 40 cm	20-30 cm
	breadth	1 to 1.5 cm	.5 to 1 cm	.3 to .5 cm
Seeds	length	2 to 2.5 cm	2 cm	1 cm
	breadth	.7 to .8 cm	.3 to .4 cm	.2 to .3 cm
	hair length	2 cm	1.5 to 2 cm	.7 to .8 cm

There is then an intimate fusion between the two parent species. This is a good example of a species cross of the type already studied with so much interest by KÖLREUTER, GARTNER, FOCKE, etc.

The largest proportion of hybrid characters are intermediary; the leaves of the Japanese Catalpa are pubescent on the upper surface, and glabrous on the lower surface; with the American Catalpa, the upper surface is glabrous and the lower surface hirsute. The hybrid resembles both parent species, and is velvety on the upper surface, and sparingly hirsute on the lower surface of the young leaves.

There are certain points which show a predominant resemblance to one special parent; for example, the bark is smooth and the margin of the leaf three lobed like *C. Kaempferi.*

The dimensional characters of the hybrid are intermediate except in the diamater of the trunk, size of leaves, and inflorescences. In these the hybrid clearly excels its parents, thanks to to its stronger development generally. *Catalpa bignonoides* × *C. Kaempferi* also distinguished by its resistance, at low temperatures to leaf spot, *Macrosporium catalpae* E. and M.

Experiments have not yet been made with F_2 when the characters are distributed, with the result that numerous forms appear, some of which could doubtlesss be picked out and propagated.

The hybrid is identical to the "Teas' Hybrid Catalpa" which very likely was produced by the cross *Catalpa bignonoides* × *C. Kaempferi.*

518 – **Seed Survey Report 1919 in Canada.** — EDDY, F. D. (Chief Seed inspector Dominion Department of Agriculture, Canada), in *The Agricultural Gazette of Canada*, Vol. VI, No 12, pp. 1033-1035. Ottawa, Dec. 1919. SEEDS

The war greatly interfered with the regular channels of seed trade in Canada and the United States. For many kinds of seeds, particularly root and vegetable, the American continent had been depending largely on European supplies. But the war having interrupted seed production in Europe, and owing to the difficulties of transport, it was impossible for Canadian and United States seedsman to secure delivery from overseas of many kinds of seeds and the production of seed on the American continent was undertaken on a larger scale than ever before. The situation was further complicated by poor crops of some kinds of seed in America; and it was considered advisable to institute more strict government supervision of seed distribution.

A special Seed Reporting Service was established under the Bureau of Markets by the United States Government to procure and distribute information respecting seed supplies, and the Seed stocks Committee was formed to advise the War Trade Board respecting the issuing of export and import licenses for seed shipment. In Canada, the seed Branch acted much in the same capacity as the Seed Reporting Service and the Seed Stocks Committee did in the United States Department of Agriculture. One of the most important features in connection with securing information regarding the available seed supplies, has been the semi-annual seed survey

Seed survey. June 30, 1919.

N. B. — OS produced over seas — AM — produced in American continent.

conducted concurrently in Canada and the United States. Seedsman and seed growers were required to make returns showing stock on hand, total receipts and exports at or during stated periods. With this information it was possible to know whether seed requirements for the season were in sight, and to give reliable advice respecting applications for trade permits.

The first survey was conducted in the United States on February 1st, 1918. This was followed by three others on July 1st, 1918, January 1st, 1919 and June 30th, 1919. The complete figures of the surveys made in Canada on June 30th (1) are presented in the adjoining Table.

The principal items reported as exported during the year ending June 30th, 1919 are as follows (pounds in all cases): Red Clover, 850 165; Alsike 10 019 462; white clover 8 000; Sweet clover; 1 016 126; Timothy 404 266; Canada Blue Grass 615 994; Common Spring Vetch 492 000; Hairy Vetch 22 544; Dwarf Snap Beans 61 641; Garden Pole Beans 96 000; Garden or Canning Peas 8 640 594.

CEREAL AND PULSE CROPS

521 - **Experiments in Sowing Barley, made from 1909 to 1915 in Denmark.** — IVERSEN R. (136 Beretning fra Statens Forsogs wirksomhed i Plantekultur) in *Tidskrift for Planteaol*, Vol. XXVI, Pt. 3, pp. 377-417. Copenhagen, 1919.

Experiments were carried out to determine the influence exercised by the quantity of seed and the method of sowing on the yield of barley and on lodging. The idea was to compare broadcast sowing with sowing 10 to 20 cm. between the lines, with different quantities of seed, limited to from 76 to 180 kg. per hectare. These experiments lasted 7 years, 1909 to 1915, at 4 Danish Agricultural Stations (Lingby, Tystofte, and Askov Lemmerk). The barley employed was a local variety (Tystofte Prentice), Archer type. Cultures were made in sixfold and tenfold plots, as a rotation crop following forage crops or legumes, and well manured. The yield in grain and straw was determined in hectolitres and also the size of the grain; a valuation scale was used for the amount liable to lodging (1 to 10).

From the results, it can be concluded that the seed sown broadcast gives nearly the same amount, quantity and quality as that sown on the 10 cm. between the lines system.

The more important factor would be not so much the manner of sowing as the quantity of seed employed: it is this factor which determines the different possibilities of development in cultivation and perspective yield. It should also be noted that seed sown on the 20 cm. between the line system produces, on an average, 1 quintal of grain less per hectare than in the lines 10 cm. apart.

(1) This service has been suspended; a résumé of the results obtained will be given shortly in a *Review*.

These results confirm the observations made by CAR. SONNE on the relation between seed employed and conditions of development. It can generally be assumed that the more the conditions of development are satisfactory the less seed is necessary to obtain the maximum yield. The barley seed sown in lines 10 cm. apart gave the following results :

Total harvest per ha. (grain and straw)	Quintals of grain from obtained per hectare		
	109 Kg.	133 Kg.	160 Kg.
90 quintals	41,0	40,3	40,2
75	33,3	34,3	33,3
60	29,9	30,5	31,3

As to the weight and the size of the grains, they increase when the quantity of seed employed decreases. Experiments appear to indicate that in employing relatively small quantities of seed, lodging can in limited areas be obviated. However, that has no value in practical farm work, seeing the quantity of seed which it is necessary to use in agricultural practice.

FIBRE CROPS

522 – **The Cultivation of Cotton in the French Colonies.** — I. La culture du cotonnier dans les colonies françaises, in *Le Bulletin des Halles, Bourses et Marchés*, Year I, XXIV, No. 263, p. 1. I. The cotton question is more than ever the order of the day. — There are at present 3 principal sources from which cotton is obtained ; the United States, Egypt, and India. The first of these three shows a production of $^2/_3$ the total product of cotton manufactured throughout the world. ; the third shows about $^1/_4$ the American product, and double that of Egypt. The yield in India is chiefly utilised in India and in Japan. In Egypt special superior quality fibre is found, and utilised in the fabrication of extremely fine thread. It really amounts to the fact that, for European manufacture, the only provision markets for first class matter are American, and this is absolutely dependant on the fluctuations and flexibility of production. Since the beginning of the war, considerable variations in yield were reported in the United States ; on the other hand, whilst formerly this country used up only a small part of her national cotton, to-day, these manufactures have almost doubled their production (in 1910, they used 35 % of the American yield ; in 1915, 60 %) ; therefore co-

(1) See *R.* Oct-Dec. 1919, No. 1138.

(2) See *R.* Dec. 1908. No 1355. (*Ed.*).

sidering only the upkeep of prices and the world revenue which ought to come in from their crops, the growers do not hesitate in case of need to limit the sale or to reduce the outlay in order to gain their ends.

There is then a considerable danger facing the European cotton industry, especially in France, where this industry is very important. There are 100 000 spinners and weavers occupied in this trade, representing a population of 1 200 000 people.

There is therefore opportunity to develop the production of cotton in the French colonies, and the author gives a rapid survey of the production and cotton trade possibilities in the various French colonies and the work of the Colonial Cotton Association. It is for this reason that the cultivation of cotton has taken a hold in these colonies. The experiments carried out have proved the best species of cotton fibre obtainable in each region and giving the highest yields. It is the idea to increase cultivation in such a way as to dispose of uniform abandoned sorts, with due order, to produce thread of identical quality from one end of the year to the other ; production should be intensified in these colonies and this is the aim of the Colonial Cotton Association.

II. The President of the Colonial Cotton Association reports the work of this Association during recent years in the French colonies, and lays stress on the duties that fall to its lot, and on the programme of action on which the Association should rely in order to carry out this lengthy enterprise which it has undertaken.

III and IV. Northern Africa ; especially Morocco. — The question has been largely discussed in the « *Annales de la Science agronomique* » by M. V. Cayla for Egypt, Algeria, Tunis and Morocco, and by the same author in *L'Agronomie coloniale* for French Northern Africa in particular. A résumé of this work as a whole was given in 1919. (See Note).

In the present investigation, special attention is paid to the question of cotton in Morocco. It is a recognised fact that cotton was previously cultivated in this region and was carried on to a fairly large extent fifty years ago. There are still traces of this to day. The cotton found is a hybrid producing a very fine quality fibre, about 30 mm. in length.

Owing to the climatic requirements of cotton, the chief growers limit as far as possible their plantations to the plains with a maritime climate. This necessity which appears to have been confirmed in the case of Morocco, as the result of test experiments since 1913, considerably limits the extent of territory possible for the cultivation of cotton. Economically, especially as the spring frosts are felt even on the coast, this necessitates the seed-sowing during april. Then cotton, also demands, for normal evolution, a sufficiently long period of vegetation, which means in Morocco, particularly outside the coastline area, a period between the spring and autumn frosts. What is more, the rainfall is very badly distributed in Morocco with regard to cotton cultivation. Cotton cultivation on dry soil therefore seems hardly possible *a priori* in the Cherifien Empire, and in fact, the trials carried out up to the present time, obviously confirm this opinion, anyhow for the long cotton silk varieties, the only varieties with which cultivation was attempted.

Amongst the Egyptian varieties, the " Nubari " has given the best results; 4 quintals of cotton fibre with irrigation and barely 1 quintal on dry land

It seems obvious that irrigation is necessary for cotton cultivation in Morocco, and that it could only be developed as far as water works would allow planters to have use of the water indispensable for plant development.

Although the cotton may be not be very particular from the point of view of the type of soil on which it is grown, it has nevertheless a preference for clay loam or deep sandy argillaceous soils, and there again, the possibilities in Morocco are limited.

After consideration of these conditions, it can be estimated that an area of about 20,000 hectares (situated chiefly in the Sebon valley and its tributaries) can be sown with cotton. It seems wise to adopt the triennial rotation crop system followed in Egypt, and this will necessitate the fitting up of an irrigation system to cover 6,000 hectare.

A survey of these facts indicates that the production in appreciable quantities cannot be realised immediately and will never be considerable. Allowing for a yield of 6 quintals of cotton fibre per hectare an annual production of 120,000 quintals per 20,000 hectare should be expected.

In addition to this, it should be noted that all the cottons which have been produced in Morocco have been declared of excellent quality by expert authorities on the Colonial Cotton Association.

There now remains the question of short staple cotton; the production of this is more immediately possible as it would only mean a reasonable treatment of the land, and this could be carried out at the earliest opportunity. However, it should not be forgotten that cotton needs in order to ensure success, suitable soil, well worked and manured.

The reasons for limiting the cultivation shown for the "long staple" are the same for short staple except as regards irrigation, and the possibilities of sowing are therefore greater. On the other hand, the short silk is less delicate and earlier than long silk. It is to be feared, however that owing to the small rainfall in Morocco, the production may not be sufficiently remunerative. It is wise in every case to count only on the low yield, not exceeding 2.5 quintals per ha. obtained in America under much more favourable conditions. It must also be remembered that in Morocco, manual labour is rare and dear, and it should not be forgotten that, except at abnormal periods, as at the present time, cotton cultivation, even in Egypt entails somewhat high expenses.

V. Ivory Coast. — From 1914 to 1918, the production of raw cotton in this colony rose from 0 to 2000 tons; 3 principal factories and 6 secondary, have been set up in spite of the war which considerably reduced the number of administrative staff and necessitate the use spinners and native employees. The result seems to promise well for the future and it is hoped that the Ivory Coast will be some years hence an important cotton centre.

The North Coast of Ivory shows the most promise, and especially at Booulé.

Cotton from the Ivory Coast is now known and appreciated. The question is well under consideration, and before another ten years, the problem will be completely solved and the cultivation of cotton definitely established in the colony.

VI. Soudan. — Cultivation of cotton could be extended to north of the Ivory Coast, and the author thinks that quite a large part of Soudan is capable of production. The Colonial Cotton Association already possesses 3 factories at Segou, San, and M'psoba. The scheme would engender the development of cotton cultivation in the neighbourhood of these 3 factories, in various directions, to support the Government of the Ivory Coast in the region of Khorogo, connected with Bougouni, Sikasso, Bobo-Dioulasso. Work in the country will be easy as far as Timbuktu by road and car to Mossi, (population 3 millions.) The only difficulty will be to find the necessary personnel.

VII. French Guinea. — The tropical climate in this colony has two seasons, one dry, the other rainy, and relative to this, it is suited to cotton cultivation.

However, near the coast, the amount of rainfall during the 6 months winter, which exceeds 3 m. and the persistance of damp winds, are both unfavourable factors. In Kissidugu Guinea and Liberia the showers which continue to fall during the dry season, mean a large quantity of atmospheric humidity, and are also contrary to production, and hinder the ripening of the capsules.

In every part of the colony, land suitable for cotton is found. But the sandstone which forms a broken belt round the mountainous region of Futa hinders the normal development of the crop unless the land is well manured.

From the economic point of view the question may be considered as follows: — In Southern Guinea, the farm population can devote their time successfully to the cultivation of rice, palm, and the fabrication of palm oil. Cotton cultivation does not present much opportunity, especially as cattle are scarce.

In other parts of the Colony, cotton production is bound up with several factors.

In the first place the existance of lines of communication. The existing lines of communication, are the railway from Conakry to Kankan, the rivers Niger, Niandan, and Mile, the new carriage routes from Mamon to Labé from Bissikrima to Dinguiray, from Dabola to Farhna, land also a large number of roads, several of which have been fitted up for the passage of oaded donkies. But the beasts of burden belong to Dioulas in connection with the traffic between Sierra Leone and Soudan, and are scarce.

The cultivators in Guinea, who do not possess animals ought to have their produce carried on the head from the cotton fields to the railway station or to the relays on the carriage routes.

This does not include the number of districts where cotton production can henceforth be organised north and south of the Colony, bordering on Portuguese Guinea, Senegal, North Senegal, Niger, Liberia and part of Sierra Leone *a fortiori*, the part in the neighbourhood of the Ivory Coast. Efforts should be made in districts which not do mean more than 50 km. lines of communication, railways carriage routes, navigable rivers, as enumerated above.

In these countries, the extension in cultivation will be dependant on two factors, density of population and cattle.

Following these lines, central Fouta is the most adaptable. But, as it is very hilly and the land of suitable and sound texture for cultivation is already covered to a large extent, cotton production will never be undertaken to auv large exten.

The plains surrounding Fouta, offer on the other hand, immense opportunities for cotton growing. The population is in general, it is true, very scattered. However, next to the almost deserted districts, there are others sufficiently well populated and the inhabitants can direct their attention to cotton cultivation, to a large extent, thanks to the use of the plough.

Nigeria — vallies of the Mile, Niger, Nianda — are populous. The cattle rate has been largely decreased as the result of recent epidemics, but the herds are regaining their former size. The cotton crops are graded in groups along the river banks. Canoes can be used as an economical means of transport of the rough cotton as far as the sorting centres.

This region seemed the best adapted to a combined action of the Cotton Association and the Administration, with a view to establishing cotton cultivation in Guinea.

VIII. New Caledonia. — The recent introduction of cotton cultivation into New Caledonia, and trial experiments for ten years, showed a tendency to rapid development up to 1916 suggesting that this product may become a very important factor in the agricultural production of this colony.

The adjoining table gives the quantities and values of the cotton exports since the introduction of this crop.

Year	Quantity	Value
1910	12 191 kg	21 456 fr
1911	45 419	90 838
1912	194 211	388 422
1913	163 214	249 784
1914	117 364	186 902
1915	107 748	111 185
1916	173 576	271 379

During 1917, owing to the absolute lack of direct communication which has characterised the commercial traffic between the colony and the metropolis, there was only one single export of picked cotton weighing 1870 kg. worth 3 667 fr.

In the first seven months of 1918 the local exporters after succeeding in finding a sale for the New Caledonian produce on the foreign market, exported to Australia 2 619 kg., of picked cotton, and to Japan 83,022 kg., of the said product.

The variety of cotton cultivated in New Caledonia is *Gossypium peruvianum*. Before the war this variety was highly estimated on the market at Havre, where it was sold at a price advanced 30 to 50 % above the market price of ordinary American cottons. The average production on normal land is 1 ton of picked cotton per hectare but on good soil and with dependable crops the yield may quite well be doubled. It may also be stated that the port of Nouméa possesses two granaries for cotton, which deal with the produce harvested in the Colony and the imports from the New Hebrides.

Although the cotton cultivation had spread to such an extent in New Caledonia from 1910 to 1912 that the production showed a yield of from 12 tons to nearly 200 tons, it has since become almost stationary, and it is certain that it will have a tendency now to decrease.

It is not possible to value the annual production at the moment, at more than 100 tons,

The causes of this regression can be traced chiefly to the scarcity of manual labour. which, since the war, even more than before, exist in the Colony. Local mobilisation has, indeed, cleared off a large number of workers in New Caledonia.

It appears also that the Caledonian planters, after having shown at the outset a great partiality towards this form of culture, have to-day a certain tendancy to abandon this idea in favour of the older types with high profits, such as coffee and coprah.

The matter of cotton cultivation in New Caledonia is largely dependant then, on the supply of manual labour. It is certain that only when the planters in these countries will be able to secure a sufficient number of workers will cotton yieds increase to any marked extent.

Every part of the Colony, including the Loyalty Isles is equally in favour of this cultivation.

IX. New Hebrides. — In the New Hebrides archipelago, the cultivation of cotton, although even a more recent institution than in New Caledonia, appears to promise a very bright future.

The quality of the soil and the atmospheried conditions of the New-Hebrides aclipelago, are apparently adapted in every way to this agricultural experiment, and what is more, it is certain that the difficulties connected with manual labour are less keenly felt than in New Caledonia.

The following table gives the quantities and values of the types of the New-Hebrides cotton reported at Nouméa since the establishment of commercial exportation at this port

This Table shows that the cotton cultivation in the New Hebrides continues to maintain marked progress, chiefly in Sauts Island, and an average harvest of 500 tons for the years immediately following the war.

But even there, considerable improvements could be effected if some wise decision could be reached with regard to manual labour.

Year	Quantity	Value
1912	6 392 kg	12 784 fr
1913	77 243	126 541
1914	228 733	367 456
1915	352 697	463 825
1916	549 371	361 096
1917	105 898	204 379
7 months in 1918	402 802	1 006 504

Before the war, practically the whole Caledonian and New-Hebrides yield was sent to the metropolis, but owing to the poor condition of direct communications, a certain exportation method was obvious in connection with Japan and Australia. It is desired to re-establish as quick y as possible, the direct maritime relations with France so as to favour the metropolitain markets once again with the advantage of the cotton produced in French possessions in the Pacific.

Exportation facilities constitute one of the principal factors of intensive development in agricultural work in New Caledonia and the New Hebrides. Cotton does well in all the isles of the Archipelago.

X. Tahiti. — The Tahiti cottons are some of the best in the world. They are distinguished by their fine quality and the length of their fibres, and are much sought after for the fabrication of cotton embroidery or lace work. For a long time they have held the leading place on the London market, far out distancing their rivals.

Numerous trials have been made at various intervals, either by the administration of the Chamber of Agriculture, or by special Societies, to encourage and develop this culture in the French Archipelago.

But cotton cultivation has really been given up, and the Cotton Society itself, although it is true it has established a well supplied granary, is devoted exclusively to the coconut. There is no attempt made to plant additional cotton until the 35,000 coconuts at Faaron are in full bearing.

Two principal causes are conjointly responsible to a large extent for this abandonment of cotton cultivation in the Archipelago. Firstly, the high price of vanilla; and secondly the lack of manual labour.

At the present time vanilla culture has been more or less abandoned owing to the disease which harms this bindweed and the consequent diminution in value. As also the coconut continues to show higher value, it would probably mean that cotton cultivation could be restarted with some success and procure an appreciable yield to the farmers.

There are a large number of localites suited to this crop in these mountainous islands, on the coast line or plateaux that are as yet altogether uncultivated. The Islands Sous-le-Vent and Marquises show considerable opportunities for cotton planting, especially if Chinese manual labour is employed, peculiarly adapted to this form of culture.

Of however, any attempt is made in this respect, it les with the Cotton Society to take the initiative, since it was specially formed for this purpose and directed by an Agricultural expert who has made a special study in this branch.

XI. Guadeloupe. — At the present moment cotton cultivation hardly exists. It has been stopped in Guadeloupe, and in the Grande Terre for several reasons:

(1) lack of information with regard to this particular crop, and insufficiency of tools.

(2) high prices of sugar-cane as supplied to the factories and distilleries.

(3) mobilisation has weakened the strength of agriculture and industry. The majority of workers in the field were settled on land grants and not on extensive property. Manual labour was therefore scarce, and the few labourers obtainable required too high a pay to plant and harvest the cotton.

The districts where this culture can be instituted and urged forward are in the Grande Terre; Anse, Bertrand, Canal, Moule, Saint-François. These are great sugar-cane producing centres, and the cotton cultivated is utilised in the manufacture of mattresses. In Guadeloupe: the southern part of Ballif. the dependaucies: Marie-Galante, les Saintes, Saint-Martin and Saint-Barthélemy, give the practical total of the annual production. An extension of plantations would be possible in these islands.

In Guadeloupe, it is necessary:

(1) that the Cotton Society pass a fixed order for the negociants of Pointe-à-Pitre;

(2) that the sale price be superior or at least equal to that offered in the neighbouring colonies.

As the cost price of cotton is determined by the run of the chief markets in Liverpool, Hamburg, and Havre, the preceding suggestion could be carried out if the buyers, the Colonial Cotton Association, the Colony or the State added a premium to the stated cost.

An experimental field should be established, with an agent specially appointed to instruct the planters, and to make a careful selection of the grains, the consignment of the best seeds (the cotton which will fetch the highest prices), and the distribution of small pamphlets on cotton will all help very much to the exten sion of this cultivation in the Antilles.

At the Experimental Stations, trials with machinery could also be made.

XII. CAMBODIA. — The *Bulletin de l'Association cotonnière coloniale*, gives the report that M. MARTIN DE FLACOURT (Chief of the Agricultural and Commercial Services at Cambodia) presented to the Colonial Agricultural Congress in Paris, 1918, on the "Possibilities of Cambodia for cotton growing. A résumé of this report was given in 1918 (1).

523 - **Agaves in Africa and Particularly in East Africa** (2). — I. HAUTEVILLE in *Journal d'Agriculture tropicale*, Vol. XIX, No 159, pp. 260-263. Paris, May 31 1919. — II. VUILLEUMIER R. *Ibid.*, No. 162, pp. 340-341, figs. 2 Paris, Nov. 30 1919.

I. The author refers to the articles in *Tropical Life* (3) 1918 on *Agave rigida* var. *sisalana* plantations, which cover a considerable part of East and West Africa (4) special attention is called to certain plantations on marshy land associated with one of the German companies (5).

The author has several times expressed doubts as to the possibility of cultural and financial success under such conditions. Having stated, in order to have the matter properly controlled, the absolute hasard of planting the agave on very dry land and in a very dry climate although admitting that this was less outstanding in the case of var. *sisisalana* than for var. *elongata* and less still for *A. Cantula* (6) and less still for *Fourcroya*, spp. he could not agree with the adventurous statement circulated by business men which had not yet been supported by any specialist. It is not whether a plant can thrive here or there, which the planter should consider, but whether it will keep all the qualities necessary for the justification of its cultivation on a large scale.

The author discusses the yields mentioned in *Tropical Life* (7) and takes the opportunity of comparing these yields, following the standard of the most leaves possible in the least possible time, (it appears that *A. sisalana* develops a flower stalk and dies in about 6 or 7 years in Africa) with the yields obtained in Mexico, where there is not such a good crop per year but where it lasts over a period of 20 years.

(4) The agave in the old German tropical colonies in Africa. See *Bull.* March 1913, No. 250. *Bull.* July 1915, No. 767; *Bull.* Oct. 1913, No. 1150; *Bull.* Jan. 1914, No. 11; *Bull.* Apr. 1914, Nos. 195 and 300. (*Ed.*)

(5) See *Journal d'Agriculture Tropicale*, No. 69, March 1907. (*Author's note*)

(6) See *Bull.* Feb. 1920, No. 203.

(7) See *Bull.* Jan. 1920, No. 46. (*N. of R.*)

The average yield obtained, as reported for 1 year, is higher in the second case than the first.

On the other hand, the author notes that to cut after 3 years has always been considered premature ; the agave has then a supple, fine and silky fibre, but non-resistant, and the vigour of the plant suffers from this premature operation.

African agave plantations are scarce because the climate and soil are neither of them suitable, because they are worked too soon, and perhaps improperly, as it is to be feared that the planters do not allow a group of 22 to 22 leaves to remain on each stalk to maintain its vigour.

The author. with reference to an assertion made by HERSON that the examples of stock proceeding from suckers is strictly limited to that of the parent plant, says that it is the first time such a thing has been. notified, and he declares that he possessed at La-Pho (Tonkin) various agave stalks which are 5 or 6 years old and come from suckers rising from the parent stalks ready for sending up their flower stalks, the signal of their approaching death.

II. — As a result of the article by M. LEON HAUTEVILLE (1), the *Journal d'Agriculture tropicale*, received from M. René VUILLEUMIER, Agent-Consular of France at Quelimane and Director of the " Empreza Agricola do Lugella " a note in which the author describes the experiments. On the land in question, the *Agave rigida* var. *sisalana* produces its flower stalk after about 5 ½ to 6 years. The cutting can be begun about the 3rd year, and carried on then under normal conditions for 2 ½ years. Each year a healthy plant gives from 60 to 80 leaves, average weight 700 gm., making an average total of 175 leaves per plant. The fibre yield is from 3 to 3 ½ %.

On marshland, there is no hope of success.

On the plantations, the spacing is 2 × m. or 2 × 2 m. The first arrangement is preferable for intercropping, which is practised for the first two years ; the first year with cotton, the second with maize.

Experience shows that, to establish a plantation it is wiser to plant out after a year in the nursery. Plants from suckers do not develop so well, and may have a shorter life (by 2 or 3 months) than those from bulbils, but it is quite out of the question that these plants may have an existence limited to the same extent as the parents ; it is pure imagination, and the author has personally undertaken various experiments wich have given altogether negative results. On the province, a plantation of about 150,000 cuttings was made in January 1915, and taken from suckers from parent plants which had only lasted until the end of 1915 ; not one of these plants had produced its flower stalk at the end of 1919. The plantation of the " Empreza Agricola do Lugella " has at present 4 millions of cuttings with 2 millions of bulbils in nurseries.

524 - **The Dwarf Coconut in the Federated Malay States.** — HANDOVER W. P., in *The Agricultural Bulletin of the Federated Malay States*, v. VIII, n° 5, p. 295-297. Kuala Lumpur, sept.-oct. 1919.

The increasing rise in the price of copra having given renewed activity to coconut planting in this country, it is important that some facts of this interesting variety of coconut should be put on record.

Description. — The dwarf coconut known in this country as « nyiur gading » is remarkable for its early fruiting palms only 10 feet high, bearing abundant fruits touching the ground. The young palm grown under good conditions starts to flower in its third year and produces ripe fruit in about nine months from the appearance of the flower spike. The initial flower spikes contain only male flowers, but other spikes occurring in rapid succession, are larger and bear an increasing number of *female* flowers one spike from a six-year-old tree bearing 200 young *female* flowers, whilst trusses of fruit from similar trees have been found with as many as 55 ripe nuts.

The dwarf coconut is generally of a bright yellow colour. There is besides, a distinct brick-red variety, also a green variety and a number of intermediate colours which might be ranged as ivory yellow " gading ", golden yellow, orange brick red, green bronze, and deep green. The flower spikes, leaf bases, and leaf ribs, correspond in colour with the fruit, giving the compact trees a very handsome appearance. Again there are semi-tall trees of these different colours, which are later coming into bearing, have slightly larger nuts, and are less prolific than the true dwarf.

The dwarf yellow strain appears as the most prolific, whilst the other varieties vary proportionately in their productiveness and also in the shape and size of the nut and are evidently the outcome of cross fertilization from original types or " mutants " (1).

The different varieties are distinguished amongst the Malays and Javanese under particular names, such as " nyur ", " (klapa) gading", " k. merah, (or sàjah)", " k. kapak ", " k. pisang ", " k. puyok ", " k. hahi ", " sepang and, " k. nipah ".

A full grown leaf of the " nyiur gading " measures only 12 feet from base to tip, whilst the ripe nut measures 22 ½ in. × 24 and the stem 24 inches in girth, the nut has an average amount of fibre, a thin shell, and proportionately with the big nut, a good thickness of white kernel.

This " meat " is said by the Malays to be richer in oil and sweeter in taste than that of the big coconut and it is therefore very popular with them for domestic purposes.

History. — In spite of diligent enquiry it has not been possible for the author to find out the definite origin of this dwarf nut, but it seems first to have occurred as a " sport " or " mutant " probably in Java. Trees,

(1) Certain curious variations have been observed in the coconut tree: see n° 514 of this *Review*. (*Ed.*)

thirty years old or so, occur in different parts of the peninsula and many of these still bear abundantly.

In 1912, 500 acres were planted with these dwarf nuts at Sungei Nipah Estate on the Coast between Port Dickson and Sepang Point and this is probably the only estate of dwarf coconuts in the world.

Growth. — Like all coconuts, this dwarf form appears to be exceedingly hardy, growing well either in white clay, red loam, or deep peat, in fact it seems to thrive in any situation where water is abundant, yet not stagnant, though it is evident that well drained alluvium suits it best.

In such a soil six-year-old palms have been counted with 234 nuts (excluding ovules), and the trees average 80 nuts a year.

Crop. — In the first year of production at Sungei Nipah the crop over 225 acres was 102 000 nuts whilst the second year it was 574 000 nuts and the third year it will probably be nearly a million; from which the author considers an average yield for dwarf nuts may be estimated as follows:

At the end of	4th	year =	1st	yielding	year	10	nuts per tree	
	5th	»	2nd	»	»	30	»	
	6th	»	3rd	»	»	60	»	
	7th	»	4th	»	»	80	»	
	8th	»	5th	»	»	100	»	
	6th	»	6th	»	»	120	»	(in full bearing).

These estimates in face of yields from individual trees will appear conservative, but there are many points which have to be considered when dealing with *average* yields, and no doubt under ideal conditions a much higher average could be obtained.

In making *copra*, it has been found that the nut from a young tree is smaller than that forming later, and its kernel likewise thinner, whilst of course, on heavy yielding trees the nuts are a little below the average in size, but 500 nuts to a pikul (1) of copra is a general average, which would be decreased somewhat later as more even nuts with thicker "meat" are obtained. With the leaf length only 12 feet it was found convenient to plant the palms 24 ft × 20 ft which gave 90 to the acre, a number nearly double to that required when planting big palms.

It is evident therefore that with this planting we should get, say, in the fifth year of planting 90 × 30 nuts = 2700 nuts per acre $= \frac{27}{5} = 5\frac{2}{5}$ pikuls copra per acre. Likewise, in the ninth year 90 × 120 = 10 800 nuts per acre $= \frac{108}{5} = 21\frac{3}{5}$ pikuls copra per acre. Comparing this with the big coconut which does not produce till *after* its fifth year it might be estimated as giving in its ninth year 45 trees at 40 nuts = 1800 nuts per acre $= \frac{1800}{220} = 8$ pikuls of copra per acre. With the dwarf trees there is the great advantage of easy and rapid picking,

(1) 1 pikul = 133 1/3 lb.

and inspection for beetles and other pests, though of course in manufacture almost 2 ½ times the number of nuts per pikul of copra handled, but this is not of so great a consequence when working with newly devised methods and machinery, dealing with large quantities.

The profit per acre from five-year old dwarf coconuts to-day can even stand comparison with that of rubber, and the man who is planting to-day, has to consider markets five years a head and might do worse than place confidence in the dwarf coconuts.

525 – **Utilisation of the Fruits of *Melia Azedarach* as a Source of "Mangora" Oil.** — De Wildeman, E., in *L'Agronomie Coloniale, Bulletin mensuel du Jardin Colonial*, New Series, Year IV, 1919-1920, No. 27, pp. 74-77. Paris, November-December, 1919.

Following on the article (1) by M. L. Rigotard (which appeared in the same publication) on the possibility of using the fruit of *Melia Azedarach* L. as a source of alcohol, the author quotes other ways in which this fruit can be utilised and certain uses for the plant itself.

The author collected, in 1903 and 1905, the scanty data available on the uses of the various parts of this plant (2), especially as regards the fats, and published them in one of his works.

Melia Azedarach, known in the Belgian Congo as "Lilas des Falls" is not, as has been thought, a native of Africa, but has been introduced, as has happened in most tropical and subtropical regions. It is a tree which may reach 30 ft height, with a short, upright trunk, and a wide crown that bears clusters of white flowers with a violet tinge. Its wide distribution, largely through human agency, has led to investigations on its pharmaceutical value, which may possibly be of a certain importance.

The plant, also known as the Persian lilac, or bead tree, grows very rapidly, even in poor soils ; its is, however, very sensitive to constant damp, as its roots rot easily. At an age of 4 or 5 years, the plant is from 20 to 23 ft. high, 1 ft. 6 in., in circumference, and bears fruit and flowers throughout the year.

The author cites a research carried out by M. J. Ondenampsen on the chemistry of this plant, and in which the properties attributed to it almost everywhere are described (3). According to him, the fruit can yield, on expression, 50-60 % of a dirty yellow fat, which liquefies at about 35° C, and rapidly turns rancid. This oil, known as "mangora" oil, can be used for soap-making, lighting, painting, and in medicine.

According to Fendler, the fat content of the pulp is too small (2 %) to allow this part alone of the fruit to be used ; the seeds contain more (39.36 %) ; in proportion to the whole fruit, the content is 4.62 %. To

(1) See *R.*, July-Sept., 1919, No. 983. (*Ed*)

(2) De Wildeman, *Notices sur les plantes utiles ou intéressantes de la Flore du Congo*, Brussels, 1903-1906, pp. 42 and 486. (*Ed.*)

(3) J. Ondenampsen, *Bydrage tot de kennis can Melia Azedarach* L. Utrecht, 1902.

make exploitation economic, the pulp would apparently have to be separated, which would require considerable labour.

These two opinions, therefore, do not agree.

FENDLER also considers that this oil could not be used as human food, but says that it could be used in the manufacture of varnishes, while repeating that its extraction is not commercially possible.

The green fruit has been used in Texas for making boot-polish, and in Georgia, after fermentation and distillation, for making a kind of whisky said to be superior to alcohol made from wheat and rice, although the fruit is reputed to be poisonous. However, the fruit is eaten without ill-effects and even with eagerness by goats and sheep.

Besides the medicinal use of *Melia* and its possible industrial utilisation, the wood is of a certain value. The wood is of a whitish or pinkish yellow colour and is hard and resistant ; the annual rings are brown and give fine veining ; the grain is close and fine and gives a good polish with pleasing reflections. The wood can be used for joinery or cabinet-work ; it is much in demand in China and Japan for the manufacture of musical instruments.

Some authors consider this wood to be of little value ; in Martinique and Guadeloupe it is said to be soft, brittle, and only good for firewood.

Two varieties are reported from Indo-China, the " Koan Ha ", with reddish wood, and the " Koan Trang ", with whitish wood, both prized varieties, especially for their resistance to the attacks of termites.

It has been suggested that Melia should be used for replanting land unsuitable for cropping, and then delicate plants, such as coffee, can be grown under its shade.

The seeds germinate easily, and the young plants can be transplanted quite well when 12-14 in., high.

This plant, then, mainly grown for ornamental use (flowers), is worth the attention of planters for other reasons.

But conflicting opinions have been expressed above ; the author stated some time ago that certain characters of the oil and the name of " Maryosa " oil probably belonged to the products of another species, *Melia Azadirachta* ; so that certain authors, e. g., LEWKOWITCH, may possibly have confused *Melia Azedarach* with *M. Azadirachta*.

These contradictory data should be cleared up by research and, above all, the correct botanical name of the plant should be ascertained.

526 - **The Seeds and Oil of " Eno Abura " (*Perilla ocymoides*) from Japan.** — See No 584 in this *Review*.

527 - **The Utilisation of *Acacia decurrens* in India.** — MACKENZIE, C. E., in *Science and Industry*, Vol. I, No. 7, pp. 430-432. 3 fig. Melbourne, November, 1919.

Much progress has been made in South Africa in the utilisation of the Australian acacias, especially *Acacia decurrens*, for the preparation of industrial tanning extracts. Like the Australian eucalyptus, which is grown on a large scale in various countries such as California, Italy, and India,

where it is more highly valued than in its native country, the Australian acacias have attracted much attention in South Africa.

The author is connected with an enterprise which intends to start a plantation of *Acacia decurrens* in India, to utilise the tree for the production of tanning extracts for the Hindoo tanneries and to supply acetic acid for coagulating rubber latex, for the manufacture of explosive and other products such as methyl alcohol, formaldehyde (obtained by distilling the wood) and brown paper (from the bark after the tannin is estracted).

A 250-acre experimental plantation, situated at an altitude of 7 500 ft. under the tropics, in the Nilgiri Hills (S. India) is now growing. In order to obtain more rapid growth and to obtain a greater area of jungle on which to plant the crop, new land concessions have been obtained in the Wynaad plateau, at an altitude of 3000 ft. on the same latitude (11° N.). The annual rainfall amounts to 2.815 metres a year, and the temperature varies between 60°-105° F (15 50°-40 56° C). The Government has granted 6 000 acres free of taxes for the first 5 years, after which period, taxes will be paid on the area not brought under cultivation. The trees can be barked after 5 years' growth.

Plantation consists in putting 2 or 3 seeds of *A. decurrens* in holes spaced 6 × 7 feet apart, which gives 1000 trees per acre. From results obtained at the experimental plantation in the Nilgiri Hills, the yield of bark is 25 000 lb. per acre, and of green wood over 100 tons per acre.

The results of analyses of the bark and distillation products obtained from wood from the above-mentioned experimental plantation are given below.

RUBBER, GUM AND RESIN PLANTS

528 – **Present State of Camphor Production: Experiments on Growing the Camphor Tree.** — CAYLA, V., in *L'Agronomie Coloniale, Bulletin mensuel du Jardin Colonial*, New Ser., Year IV, 1919-1920, No. 28, pp. 97-109, 1 plate. Paris, Jan.-Febr., 1920.

Amongst the raw materials utilised by Western industry, and which have to be entirely imported, camphor attracts notice on account of the rapid and heavy increase in its price, especially in 1919.

Prices remained normal until 1915, and at the end of 1914, they were still at 4.25 fr. per kg. The successive stages of increase in prices during subsequent years were as follows (1):

Variations in the price of camphor, 1915-1918.

		fr.		fr.		fr.
1915	—		June	4,60	Decembre	6,25
1916	March	5,15	July	6,00	Octobre	8,50
1917	February	10,00	June	9,25	»	10,50
1918	February	16,50	July	15,50	»	25,00

Year 1919.

May	32,00 fr	August	50,00 fr	November	70,00 fr
June	38,00	September	55,00	December	80,00
July	45,00	October	57,00		

Part of the increase in 1919 is obviously due to the depreciation of the franc on the world's market. All the same, there is an enormous increase in price.

Japan controls the world's camphor market, and, on account of the increased consumption of camphor in Japanese industry, the exports of camphor from Japan have decreased, thus causing a crisis in the European celluloid industry.

If France in particular does not wish to have to buy crude or even manufactured celluloid, she will either have to produce synthetic camphor or exploit the camphor laurel.

There are many processes for producing *synthetic camphor*, even if the quite different material known by chemists as *artificial* camphor be not included, as it cannot replace natural camphor in its industrial uses. But the only processes worth industrial exploitation require terebenthine oil as a raw material, and the industry making the synthetic product, which, owing to the high price of the natural product, established in 1907, was not able to carry on, on account of the high price of turpentine and the drop in the price of natural camphor. Nowadays, the establishment of factories is a costly and lengthy process. Most of the processes, only worked out on a laboratory scale, would require time to perfect their industrial application, and no speedy solution of the camphor crisis in expected in the manufacture of the synthetic product.

Exception being made of the many plants that produce camphor in small amounts, the Japanese camphor tree (*Cinnamomum Camphora* Nees), of the Lauraceae family, is the only plant that has been and remains the type of plant that can be exploited industrially. This is a tree occurring in large numbers in the forests of the Japanese archipelago, Formosa, Hainan, central China, and the province of Fokien (China). Practically the whole of the 6000 tons of camphor which represents the maximum

(1) These figures, furnished by M. L. Michel, President of the " Syndicat général de la Droguerie française ", répresent the value in francs per kg. of refined camphor. (*Author*).

annual consumption was and is obtained from these regions. Exploitation consists in felling trees at least 40-50 years old ; the wood is reduced to chips, from which the camphor is extracted by distillation in a current of steam. The crystals of crude camphor which are deposited in cooled recipients are pressed and finally refined in special refineries. A liquid, known as " oil of camphor ", is also collected and constitutes an important by-product.

This method is obviously crude and is leading to a rapid destruction of the forests, even if officially controlled. China, with its continental provinces, and with Formosa, was for a long time as important as Japan as a source of camphor. The cession of Formosa to Japan gave that country all the insular production, which was at once made into a State monopoly, not only as regards the exploitation of the forests and the extraction of camphor, but also as regards its refining and sale. The sale price is fixed by the State, whose representatives buy the crop from the producers at a price which is fixed anually. To prevent any competition from China, Japanese commerce has made itself absolute master of the Chinese camphor, exported chiefly through Shanghai, Foo-Chow and Amoy. By raising or lowering the price of camphor, Japan stimulated or discouraged the exploitation of the Chinese forests, over which there is no control. In fact, Japan, is the absolute master of ahe Far-Eastern production, and therefore of the world's consumption, as practically all the camphor consumed in the world comes from the Far-East.

Experiments have been carried out for years on the extraction of camphor from the leaves and young branches of younger trees, which thus would not be killed. Eight or ten years ago, it was said that, as a result of encouraging experiments, Japanese technicians placed all their hope in the extraction of camphor from the leaves. In 1913, and again in 1919, it was reported that these hopes were not fulfilled and that the Japanese relied solely on the synthetic camphor that they were going to make. However, for the last 10 years, the Japanese production of camphor has not decreased — the preceding figures show it — and one is forced to the conclusion that either the forests were not as exhausted as they were said to be, or that camphor was extracted from the leaves, for the author rejects the hypothesis that synthetic camphor was manufactured in the archipelago and sold as natural camphor.

Exploitation by felling the trees and distilling the wood can only be carried out in the Far East, as old forests of *Cinnamomum Camphora* are found nowhere else. In the other tropical and sub-tropical countries into which the camphor tree has been introduced, all that can be done, if the tree is cultivated, is to distill the leaves and young branches. As regards this, all the information that Japan has furnished is that the yield is too small to be of interest. The author reviews the experiments that have been made in various countries on this subject.

The yields of camphor obtained in these experiments were very variable, for various reasons. Firstly, in the distillation, certain of the methods give rise to losses, and then the percentages refer now to the weight

of fresh matter, now to the weight of dry matter. In the latter case, there are variations according to whether the drying was natural or artificial, in the sun, or in the shade, under one climate or under another. Many of the results take no account of the camphor oil, which is a solvent of camphor. The content of camphor varies according to the season, the temperature, the age of the tree. All these varations occur in material from one tree. Also there are various botanical species or varieties of camphor tree, with varying contents of camphor. Even in Japan, FESCA has recorded 3 varieties, each with a different content. The camphor trees in Indo-China which, according to CRÉVOST, have been introduced, as they are found in the forests only around the pagodas, apparently belong to several distinct species. There is the "true" camphor-tree, which yields camphor, and the "false" camphor-tree, which does not. Amongst specimens sent from Tonkin, DUBARD found *Cinnamomum Camphora* and *C. cecidodaphne* var. *caniflora*. Amongst Italian camphor-trees, Prof. GIGLIOLI identified *C. Camphora*, *C. glanduliferum* and their hybrids. Dr. TRABUT has shown that HARDY'S camphorless camphor-tree, in the Algiers Botanic Garden, was not *C. Camphora*, but a hybrid, and analyses made by L. MUSSO (1913 and 1919) confirm the supposition that a difference in content corresponds to a specific difference. It was found at Kew that the old camphorless camphor-tree (it only yields camphor oil) of the Botanic Garden of St. Vincent was *C. Camphora* var. *glaucescens*. However, the camphor trees in Mauritius, which only yield camphor oil — very different from the product sold under that name — really do belong to the species *Cinnamomum Camphora*.

It has been mentioned that often no account is taken of the oil of camphor produced and that it was rare to find its content of crystallisable camphor given. All the same, this is a point that should not be neglected when estimating the total yield of camphor from a tree.

In any case, the oil itself, freed from dissolved camphor, is of interest, for, on fractional distillation, it yields two valuable products: *safrol* and, in smaller amount, *eugenol*. Here again there are variations, as camphor oil yields more or less of safrol or of eugenol, or nothing of one or the other, without it being known if these differences are due to the influence of the environment or of the botanical origin.

All this shows how much research is still required on the camphor-tree, its cultivation and exploitation, on botanical questions, etc.

The unit yield also must be calculated. This depends on the age of the trees, the number and extent of the cuts given them, the period during which the cuts were made, the method of planting (number of trees per hectare), etc. LOMMEL, according to AMANI'S experiments, estimates that, with 2 annual cuts, a yield of 145 kg. of camphor and 46 kg. of camphor oil per hectare can be obtained. According to S. C. HOOD and R. H. ERIC, trees 2.5 metres high, planted 4.50 metres × 1.80 metres, with two annual cuts, will give from 200-225 kg. of marketable camphor per hectare per year. Other figures have been calculated but it is difficult to say that they are definitive.

But, though RIVIÈRE has declared that the camphor-tree will not bear cutting, even if only repeated once every two years and over half the tree, most English experts state that its is not harmed, that its growth is not affected by one, two or three annual cuts according to its age, each cut affecting ⅓ of the foliage at most.

The objections to this method of exploitation are mostly of an economic nature. Prof E. W. HILGARD say that, in California, this crop cannot be grown on account of the high cost of labour. CH. RIVIÈRE also states that removing the leaves would be difficult and expensive and that at any rate in Algeria the tree could not be exploited before the age of 25 years. Most British or American workers give 4 to 8 years as the age at which exploitation can begin. However, this point requires investigation.

The author thinks that researches and experiments should be carried out in the French colonies. In Indo-China, there are camphor-trees that could be exploited and multiplied. In most of the French possessions, including North Africa, experiments could be carried out, and practical cultivation experiments are necessary in all those colonies.

SUGAR CROPS

529 – **Action of Heat on Sugar-Beet Seed.** — SAILLARD, E., in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. VI, No. 11, pp. 308-311. Paris, March 17, 1920.

Acting on the suggestion of the Official Sugar-Beet Seed Commission, the French Ministry of Agriculture has opened a competition for apparatus for drying beet seed. The competition will take place in March, 1921, and two prizes, one of 30 000 fr. and one of 20 000 fr., are offered.

The object of drying is to improve the keeping and germinating qualites of the seeds. According to M. SCHRIBAUX, beet seed can be kept at a temperature of 70° C for several hours without being harmed. The conditions of the competition make allowance for this observation.

The author has investigated the action of temperatures above 70° C. on the vitality of the glomerules, comparing them with temperatures below 70° C. The experiments, in which M. WEHRUNG collaborated, bore on seeds of varying quality and age. The seeds were heated in an oven with a thermo-regulator, a closed oven in which the air could be changed, or in an ordinary oven ; the seeds were not shaken during heating. Germination was carried out on damp sand in an oven kept at 25° C. The germinated glomerules were counted each day and those that had not germinated at the end of 22 days were assumed to have been killed.

1st series of tests. — Seeds of 3 qualities, very good (*A*) good (*B*), bad (*C*), showing respectively after 14 days, a germination coefficient of 98 for *A*, 78 for *B*, 36 for *C*, were respectively heated for an hour at 40, 50, 60, 70, 80, 90, 100 and 105° C, then germinated at 25° V, for 22 days in parallel with unheated controls. Some of the results obtained are given below.

It is evident that, the good seeds germinated more quickly and resisted the heat better than the poor ones.

2nd series of tests. — The same seed *A*, *B* and *C* were heated for ¼,

½, ¾ and 1 hour, respectively, at 80°, 100° and 105° C, then germinated at 25° C, in conjunction with unheated controls. The appended table shows some of the results obtained.

After	Unheated control	Number of glomerules germinated out of 100 heated at for one hour at					
		60° C.	70° C.	80° C.	90° C.	100° C.	105° C.
Bad seed (C)							
3 days	0	0	0	0	0	0	0
6 days	27	28	27	0	0	0	0
14 days	36	36	37	9	2	0	0
18 and 22 days	36	36	37	9	2	0	0
Good seed (B)							
3 days	61	68	10	0	0	0	0
6 days	84	88	75	50	3	0	0
14 days	87	89	86	86	74	42	0
18 and 22 days	87	89	86	86	75	46	0
Very good seed gathered in (A)							
3 days	95	94	90	54	5	0	0
6 days	97	98	97	97	95	70	1
14 days	97	98	97	97	95	80	3
18 and 22 days	97	98	97	97	95	80	3

Duration of heating	Number of glomerules that germinated in 14 days								
	Seed A			Seed B			Seed C		
	80° C.	100° C.	105° C.	80° C.	100° C.	105° C.	80° C.	100° C.	105° C.
15 minutes	97	94	12	86	65	4	25	18	0
30 »	97	91	8	86	55	0	18	10	0
45 »	97	86	5	86	45	0	11	0	0
60 »	97	80	3	86	42	0	9	0	0

The germination coefficient continued to increase until the 18th day with regard to the heated seeds which, after 14 days' germination, had given a lower germination coefficient than the 2 controls, but without reaching it, even after 22 days.

It should be added that seed *A* was gathered by hand, as it gradually matured, and was at once dried in the sun. This is probably the explanation of its very high germination coefficient.

Conclusions. — (1) With properly applied heat, the bad or weak glomerules can be killed, without harming the good or strong ones. It is therefore, a physical means for selecting the glomerules.

(2) A temperature of 80° C, even when maintained for an hour,

did not alter the germination coefficients, after 14 days, for seed *A* and *B*; but it somewhat retarded their germination.

As the germination test was done immediately after heating, the preceding results simply show the action of heat on the vitality of the seeds, but not the action of the heat used for preserving the seeds.

STIMULANT, AROMATIC, NARCOTIC AND MEDICINAL PLANTS

530 – **Loss in Dry Matter of Kentucky Tobacco at Different Periods of Drying.** — DONADONI, M., in *Bollettino tecnico del R. Istituto sperimentale del Tabacco, Roma-Scafati (Salerno)*, zear XVI, No. 2, pp. 17--81. Scafati, October-December, 1999.

It was found that the average total loss of organic matter undergone by Kentucky tobacco during drying by direct heat was about 16 %. About $^2/_3$ of the loss took place in the first period of drying, i. e., that which corresponds to the yellowing of the leaves. As regards the importance of the changes that take place in the tobacco leaves during drying, by far the most important period is that of yellowing. The essential factor of the changes during the first period of drying is the vitality retained by the leaf after it has been detached from the stem, or after the stem (when the plant is dried) has been separated from the roots. In fact, the disappearance of the yellow colour and its replacement by a chestnut colour, indicate the complete physiological death of the corresponding tissues. For this reason, the chief elements that help to making the drying of Kentucky tobacco a success include : — The perfect state of the leaf tissues at the moment when drying commences ; the gradual and complete change in colour of the leaf from green to yellow, which shows that all the important changes correlated with the first drying period, (changes which go hand in hand with the change in colour of the leaf) have taken place.

VINE GROWING

532 – **The Resistance of Various Stocks to Drought.** — SICARD, in *Le Progrès agricole e viticole*, Year XXXVII, No. 11, pp. 256-262. Montpellier, March 14, 1920.

Communication to the "Société centrale de l'Hérault" (France), describing observations made on experimental vines during the summer of 1919, which was exceptionally dry. The author does not consider the nature of the soils, as they are dry on account of the bad constitution of their soil or subsoil, and only deals with soils which, in certain years, dry up, after climatic misfortunes like those from which most soils in the south of France suffer.

The replacement of worn-out vines or those prematurely ruined by lack of care, becomes a necessity which cannot be indefinitely postponed. Hindered or stopped by the war, reconstitution will soon recover its progress towards an ever more intensive production. To this end, the judicious choice of grafting stock is of great importance. The scientific study and practical testing of different varieties should provide rational and natural means for recognising foreign influences, especially drought, that act on the qualities of American vines and their hybrids. With an

environment whose geology, physics and chemistry is well known, it should be easy to provide solid foundations for such new reconstitution, and thus the improvement of the soils would be as complete and perfect as possible.

In the deep, strong and calcareous soils that were studied, the grafting stocks that best resisted intense and prolonged drought were the hybrids of Vinifera × Rupestris, which were clearly better than the pure Americans, the Americo-Americans, and even the Vinifera × Berlandieri. In these soils, Berlandieri hybrids did not give the favorable results obtained on shallow, dry soils, and the author adds that the resistance of a stock to drought is characterised:

(1) By a perfect adaptation of the root system to the physical properties of the soil and subsoil.

(2) By numerous thick, fleshy roots, which form a powerful apparatus for absorption.

(3) By reduced foliar development, thus limiting the evaporation capacity of the stomata.

533 - **The Behaviour of Grafted Vines and Direct Bearers in Relation to Drought, in Touraine France.** — See No. 448 of this *Review*.

534 - **The Layering of Grafted Vines.** — ROSEAU, H., in *Revue de Viticulture*, Year XXVII, Vol. LII, No. 1340, pp. 161-16. Paris, March 4, 1920.

Layering is a method of reproduction which consists in obtaining roots on a vine-shoot before it is separated from the parent plant, the shoot afterwards becoming a separate plant. To do this, the shoot is bent over and buried in a hole some 30 cm. deep. In Champagne, Burgundy and the Saumurois district, the method employed is as follows: the shoot is never separated from the parent plant, and generally the whole plant is buried, leaving only two shoots, one at the original spot and the other at the place where it is wished to obtain a new plant; sometimes, instead of layering one plant but once, it is layered in successive years; from the plant *A* two new plants are obtained, *B* at the original place of *A*, and *C* a little farther away; the next year *C* in turn is buried and treated like *A*, and so on; this practice is known as "assiselage".

With regard to the possibility of applying layering and "assiselage" to French vines grafted on American vines in spite of the attacks of phylloxera, the author discusses the arguments for and against this method, quoting experimental evidence of long standing and then gives his personal opinion as follows:

When the numerous positive results obtained in several French vineyards are considered, it may be concluded that there is no need to give up layering grafted vines. It has many advantages for the vinegrower and it is a practice that is well worth extending. Naturally there were failures in Champagne or elsewhere, but these were mostly due to indirect factors such as mildew, chlorosis, etc., when they were not the result of incompetent practice.

If failures are to be avoided, the following rules must be observed: Parent plants must be chosen that are at least 4 years old, so that

they have a vigorous root-system. The plants must be vigorous and healthy, the graft callus must be healthy and well formed, and the shoot chosen for layering must be healthy and strong.

In spring, before growth starts, the stock must be cleared of soil down to the first roots, a small ditch 25 to 30 cm. deep must be made in the direction in which the shoot is to be laid and the stock bent over on the side to which it inclines naturally. Care must be taken not to break it or damage the roots.

Finally, when the shoot is fastened down, the part that joins it to the parent plant must not be cut, as there should always be a vital connection between shoot and plant. Care should be exercised that the layering is not harmed by ploughing or other work that might damage the buried shoot. Vinegrowers should test the method in their own vineyards, e. g., in layering to replace missing trees, and this would be the best way to form a personal opinion and ascertain the value of the method.

FORESTRY

535 - **Planting Trees on Waste Heaps, Abandoned Quarries and Land in Belgium.** — CRAHAY, N. I., in the *Bulletin de la Société Centrale Forestière de Belgique*, Year XXVII, No. 3, pp. 117-131. Brussels, March, 1920.

In Belgium there are many sterile areas, heaps of stone, shale, virgin soil, ashes, accumulations of industrial or public refuse, slag banks, abandoned quarries, excavations or dumps made in the construction of railways, roads, etc., which form ugly blots that may spoil the finest landscape, and which could with advantage be planted with trees or shrubs. The author thinks that there is much to be done as regards this matter that would greatly benefit the health, the beauty of the country and, up to a certain point, the production of wood.

There is hardly any soil that cannot be overgrown by trees in time. Obviously, certain dumps of refuse or stone may be abandoned provisorily, but, after a certain time, the action of air and weather takes effect, subsidence takes place, the rocks are decomposed and soon a little soil is formed on which the vanguard of plant life can be established. Three cases can be met with:

(1) Dumps where refuse is still being deposited.

(2) Dumps or parts of dumps where combustion is taking place, as is shown by smoke, heat, or by the scorched appearance of the surrounding vegetation.

(3) Large heaps of rocks and stone with wide cracks, and which have not weathered sufficiently.

In England, waste heaps have been planted with trees for some time now and an association with over 500 members was formed for that purpose. In Belgium, the industrialists and quarry owners were quite free to change the appearance of a district and to destroy the most beautiful places which sometimes bring prosperity and riches, until June 30, 1905, when MM. DESTRÉE and CARTON DE WIART put forward a Bill for the preservation of landscapes. This Bill was favourably received during the Parliamentary session of 1911 and, after interesting debates in the Chamber and Senate, it became law on August 12, 1911. The text is as follows:

Art. 1. — Any person exploiting mines, excavations, or quarries, or any contractor for public works, must, as far as is possible, restore the appearance of the soil, by planting the excavations, heaps, etc,, with trees or other vegetation that will remain permanently. Planting must be carried out as each portion of the work is finished.

Art. 2. — In case of non-compliance with Art. 1, the person can be charged so. The action will take place in the Court of the first instance of the devastated district at the request of the king's Proctor.

It will equally affect any Belgian citizen. In case the work is not carried out within the time fixed by the Court, it will be done officially at the expense of the person exploiting the mine, etc., or owning the concession, by the Ministry of Agriculture and Public Works.

Art. 3. — This law applies to the State, Provinces, and Communes, as well as to private enterprises.

So far, this law has remained a dead letter and no steps have been taken to carry it into effect. This state of affairs will continue until the State has it carried out by the Service of Waters and Forests. Suggested measures which might be adopted are :

(1) Refusal of permission to open mines, quarries' to establish industries, to construct railways and roads unless guarantees are given regarding the site and the subsequent planting of areas that have become unproductive, heaps, excavations, dumps, etc. The deposit of surety-money may, in certain cases, be required, so as to provide for the necessary work. In 1894 and 1897, the Belgian Minister, M. DE BRUINS drew the attention of the Governors of provinces and of Forestry Inspectors and ordered that when requests for permission to open quarries, mines, etc., were made, greater attention should be paid to the question, of the landscape.

(2) To act by giving advice to industrialists to show them their duty as well as where their interest lies, for if they profit from an exploitation it is incumbent on them to allocate a small part of the profits to repair the harm they have done to everyone spoiling a landscape, as well as to make the place where their employes live more agreeable and healthy.

(3) To provide owners with land requiring planting with the help of persons competent to direct the work or forest officers.

(4) To give cash subsidies or grants in certain cases.

(5) Purchase by the State or communes, of the areas in question when they are decidedly of general interest and when reasonable terms can be obtained. This is evidently the ideal and the site would be permanently preserved.

Many broad-leaved trees do well on pit banks and quarry tips. Remarkable results have been given by the robinia, great round-leaved sallow, white alder, birch, Virginian cherry, maple, wild cherry, service-tree, beam-tree, lime, chestnut; and, under the best conditions, such as at the foot of the slopes, maples, elm, oak, ash, hornbeam, and even the Canadian poplar.

As regards mixtures, the trees should be varied according to the district, the exposure, slope, nature of the materials, but, following the usual practice in making plantations of broad-leaved trees, the species should be divided in two broad categories :

(1) Trees of rapid growth which resist exposure, bad weather, and produce shelter and soil in a short time and thus enable more exacting but often more valuable trees to be planted. This category includes the robinia, white alder, great-leaved sallow, birch, lime, service-tree, beam-tree and Virginian cherry.

(2) Trees of slower growth which take longer to become established and which like a little shelter and coolness, with which the trees in the first category can provide them ; these include the elm, chestnut oak, hornbeam, maple and ash. As a rule, trees belonging to the first class should constitute from $^1/_5$ to $^2/_5$ of the mixture.

In conclusion, it is eminently desirable, in the interests of aesthetics, public health, and even of the production of timber, that all these quarries, tips, excavations, etc., and any waste areas that spoil the landscape should be covered with vegetation.

Regarding Belgium, the Administration of Waters and Forests should be charged with carrying on the law of August 12, 1911, on the preservation of landscapes and the transformation of the areas mentioned above. As regards land of a certain area that belongs to the State, the communes, or to public bodies, they should be dealt with like any other waste land and afforested. As regards privately-owned land of a similar nature, it is advisable firstly to act by propaganda or advice, with the help of Government officials in the direction of the work, by means of grants in money or in kind (seeds and plants), or by means of purchase by the State or the communes when this is possible.

From the cultural point of view, no afforestation should be undertaken without a thorough examination of the soil and of local conditions so as to benefit nature's teaching ; in difficult cases, herbaceous or shrubby, plants should be planted in the first instance. For planting strictly speaking : (*a*) choice should be made of trees suited to the soil and district, and wide use should be made of the robinia, which has proved its worth ; (*b*) small plants not older than 2 or 6 years) should, as a rule, be used ; (*c*) trees should be cut down to the ground in 3 or 4 years ; (*d*) rabbits must be destroyed.

536 – **The Eco-dendrological Problem of the Production of Forest Seeds.** — Borghesani, G. (Federazione Pro Montibus, Comitato per lo studio scientifico per lo studio dei problemi forestali in Italia, Sezione eco-dendrologica), in *Rivista di Biologia*, Vol. I, Pt. 5-6, pp. 559-585, 1 fig., bibliography of 63 publications. Rome, 1919.

Critical review of the question of the origin of forest seeds from the scientific point of view.

The first researches on the question of forest seeds were carried out on *Pinus sylvestris* by Ph. André de Vilmorin, who introduced the Riga or Livonian pine into France in 1820 and compared it with plants grown from French, German, and Scotch seed. At first, the results were in favour of the Riga pine, but now, after about a century, this pine has not maintained in France the high forestal qualities that it shows in its original country.

Vilmorin's experiments were not followed up and, in 1860, Dr. Schübeler, at the General Agricultural Congress at Gothemburg, announced his well-known laws, deduced from a series of botanical studies begun in 1848 and embracing most of the plants and their varieties grown in Europe. These laws, which stated the superiority of seeds from the North or from high altitudes, were supported by agronomists and experts such as Tisserand and De Vilmorin in France, Wittmarck, Nobbe, Wollny in Germany, Petermann, in Belgium,

and ROSTRUP in Denmark, and brought these seeds into great fashion, from which Northern forest seeds profited as well, though SCHÜBELER had never dealt with them.

In 1887, the original and conscientious researches of CIESLAR, Director of the Forestry Station of Mariabrünn, on spruce, Scots fir, and larch, brought a true perspective to the enthusiasm of foresters for seed from the north or high elevations. In Switzerland, the necessity was also felt of carrying out similar experiments, on account of the extreme diversity of the forest soils in altitude, exposure, geological structure of the subsoil, etc., to which very different conditions of growth are due. For this reason, Prof. ENGLER, Director of the Zurich Experimental Station began researches in 1899 and published his results in 1905. They dealt with the fir, larch, and mountain maple, and fully confirmed CIESLAR'S results. On account of the importance of these researches, it is worth while to quote the principal conclusions.

After the researches of CIESLAR and ENGLER, the study of problems relating to the origin of forest seeds was taken up in those countries where the study of forestry is most closely followed (Austria, Belgium, Denmark, France, Germany, Japan, England, Russia, United States, Sweden, Hungary); special comments were made on it at the Eighth International Congress of Agriculture at Vienna in 1907 and in the different Congresses of the International Union of Experimental Forestry Stations; in this way, a plan of collective researches was drawn up by the Institutes that formed part of the Union, a plan that originated at the end of the third Congress at Vienna, in 1900, following up the subject put forward by Prof. MAYR OF Munich University, dealing with the effect of the origin of the parent plants on the seeds.

Most of the publications issued after 1905 dealt with the importance of the origin of *Pinus sylvestris*. Thus at the sixth Congress of the Union of Experimental Forestry Stations, held at Brussels in 1910, this subject was dealt with afresh and in detail and 4 reports were presented by N. S. CRAHY (Chief Inspector of Belgian Forests), Dr. ZEDERBAUER (Forestry Experiment Institute of Mariabrünn), Prof. MAYR and Prof. ENGLER. These reports gave preliminary data of experiments done or in view and suggested that forest managements should be provided with seeds adapted to the locality.

A number of measures were taken by the different States to protect forest owners against the purchase of unsuitable foreign seed. Sweden was the first to do this and, in spite of a heavy increase in the import duty applied in 1898 to seeds of Scots fir and spruce, established by the law of April 4, 1910, demanding that any imported seeds of species of *Pinus* and *Epicea* except *Pinus Cembra* and *P. sibirica*, should be stained with eosin. In 1911, in Germany, it was decided by the Forest Council to establish a union of owners of large drying machines, who undertook under the supervision of the Council itself, to use none but German cones, the idea being to eliminate the introduction of seeds from other countries, especially Hungarian and French seeds of inferior quality. It should be noted that, in Prussia, at any rate in the State forests, it is now possible to obtain suitable forest seeds, because each estate has had its own driers for some years.

In 1913, ENGLER published a 2nd series of studies, in which, using new experiments on *Pinus sylvestris* and spruce, as well as work by other authors as a basis, he showed that in certain forest trees (Scots fir, spruce, larch, maple, oak), morphological and physiological aptitudes acquired under the influence of the climate are transmitted to the progeny and finally become permanent.

In 1915 HAUCH described experiments on oaks of various origins for the Experimental Forestry Commission of Denmark, with the object of ascertaining the effect of the origin of the seed on the resulting plant.

In 1915, SHIRSAAWA published the results of researches carried out at the Forest Experiment Station at Meguro (Japan): these researches, made with Japanese seeds and continued for some 10 years after they were initiated in 1902, constitute the Japanese section of the general plan of the researches on the origin of forest seeds organised by the International Association of Experimental Forestry Stations.

SCHOTTE, in 1915, gave the latest results from researches carried out by the Swedish Experimental Forestry Institute on the origin of the seeds of the Scots fir, the third series of which dates from 1907-1908 when the Swedish section of the international series of experimental sowings with seeds of the Scots fir was worked in accordance with the above mentioned plan.

Summing up the results of these researches the author says that for the solution of the eco-dendrological problem of the production of forest seeds, the following information is now available:

(1) There are various types of the common forest trees, each of which has hereditary ecological, dendrological, and alsometric characters.

(2) For the moment, the most important of these types from a practical standpoint is that of climate.

(3) Without absolutely denying the practical value of forest selection (ENGLER), the chief question for sylvicultural technique is to recognise the value of the various climatic types for any given station.

(4) In consequence, the origin of forest seeds is of the greatest importance to the success of plantations of the chief forest trees.

(5) The failure of many plantations is due to the unsuitable origin of the seeds of plants.

(6) The provision of supplies of forest seeds gathered in the various regions is required, and such seeds should be used in their natural stations.

All this refers to the common forest trees and not to the acclimatisation of exotic trees, for which a vast field of experiment is open. In any case, even with exotic trees the origin of the seed ought to be ascertained taking care that the conditions of the natural habitat correspond to those of the new country, and while trying to obtain suitable supplies of trees already introduced which have given good results.

537 – **Action of Climate, especially Temperature, on the Formation and Germinating Capacity of Seeds of *Pinus sylvestris*.** — WIBECK, E., in *Meddelanden från Statens Skogsförsöksanstalt*, Part 17, Nos. 1-2, pp. 1-20, frgs 6 Stockholm, 1920.

Results of a series of investigations concerning the action of climate, especially temperature, on the formation and growth of the seeds of *Pinus sylvestris* in Sweden.

The author considers that the forms of pine due to the climate a subject which has recently been much examined from the systematic point of view, are indirectly related to the climate in October and November. In this work, however, and in the division of the country into thermic zone, the average annual temperature has been taken into account. There are successive, constant zones characterised by an average annual temperature less than —1° C in the first zone; included between +1° and —1° C in the second; between +3° and +1° C in the third; between +5° C and +3° C in the fourth zone; and so on.

The material studied was divided according to its germinating capacity into three groups. The first group includes germinating percentages from 0 to 40 %, the second from 41 to 50 %, and the third those above 50 %. In the appended map, Fig. 1, the third group is shown by a black dot, the second by a cross-hatched circle, and the third by a white circle.

HAGEM, whilst conducting similar investigation in Norway, observed the effect of summer temperatures on the production of seeds capable of germination for this purpose June-August temperatures must not be lower than

Fig. 1. — Production of pine seeds capable of germinating as regards the isotherms of the period June-August.

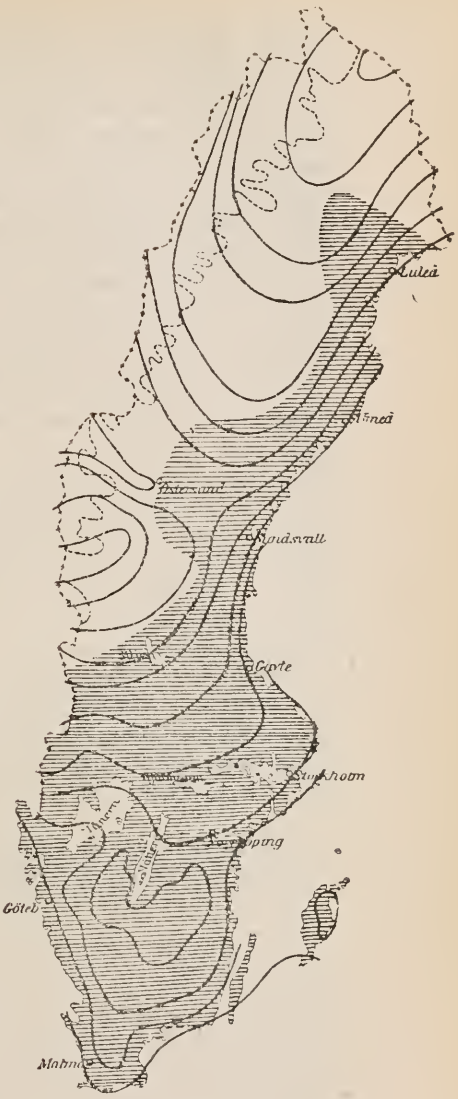

Fig. 2. — Division of Sweden into 2 regions with germination capacity respectively superior (hatched) and inferior (white) to 50 %. The curves represent the November isotherms.

+10.5° C. Similarly, the author examines the dominant effect of the June-August temperatures in Sweden The isotherm +13° C for 1916 and the isotherm +14° C for 1917 divided the country into two clear sections, one

eastern, one western. In the eastern section the percentage of seeds capab of germinating is above 60 %, while, in the western section, howeve it is below 30 %. The conclusion is, then, that to obtain a crop of see with a germinating capacity over 50 %, the minimum average temperatu during June-August must be +13° C. In Fig. 2, the horizont hatchings indicate those parts of Sweden where the average June-Augu temperature is over 13° C. These regions coincide (*cf.* Fig. 1) with tho regions where the germination is equal, or superior, to 50 %. Besid their scientific interest, these results are of considerable practical val as regards the choice of seed for study in relation to the formation of nu series, for it will be advisable, in every case to examine the coastal regio (eastern sector). The author points out the need for meteorological o servations in forests, especially during the period from June to Augus

Recent anatomical investigations appear to show that the delay germination and the poor germinating power are related to the develo ment and formation of the embryo. Material was examined from t Garpenberg reserves (Dalécarlie), a southern zone with favourable climat and from the Sikå reserves (Norbotten), a north-west zone with unfavou able climate. In seeds from the latter region, great variability w noted in the length of the embryo, usually slightly developed (length embryo in proportion to the total length of the endosperm = 19 to 89 % with an average of 61.36 %.) On the contrary, in the former locality, whi was more favourable as regards climate, the embryo, while longer on t average, was also less variable (43-92 %, with an average of 76 %.)

Owing to its growth being slow and with little intensity, the embry on account of its feeble vitality, is doomed to a slow intraseminal growt which, only after a considerable period, enables it to react to external fa tors and germinate by passing through the spermoderm.

538 – **Experiments on the Lopping of Resinous Trees.** — Note du Service spécial d expériences et constatations scientifiques forestières, in *Bulletin de la Société Centr forestière de Belgique*, Year XXVII, Vol. 3, pp. 131-140. Brussels, March 1920.

As a rule foresters are not in favour of lopping green branches in c niferous plantations, but, all the same, at times, a certain number of bra ches have to be cut. This occurs in plantations established gradually, that some trees are more advanced than others, or isolated trees, avenues, or when a first clearing has to be made. In these cases, so say that they must be lopped up to the trunk, while others affirm th a stump, which will fall on its own accord naturally, later, must be left. account of these divergent opinions, the Belgian Research Service h attempted to solve these two important questions experimentally.

Young spruce which formed a shelter belt to the Arboretum, at Gr nendael were lopped, every 15 days, starting on September 15, 1912, alwa by the same workmann. Five trees were successively sawn off cl to the trunk, the little knot of resin at the base of the branches being le the man sawed the branches of the next two trees at about 10 cm. fr the trunk. A year after, the stump was sawn close to the trunk. Th

rees were lopped with a bill-hook as an experiment. In this way, 10 rees lopped every fortnight by the same man. As a flow of resin is considered to be a sign that a tree is weakening, observations, which were egun on May 27, 1915, were nade on that basis.

The experiment showed that the best results were obtained by opping so as to leave a stump, which was sawn off a year after. It should, owever, be observed that the wounds were not completely callused and hat the time required to complete callus formation is of prime importance n forming an opinion as to the value of the method. Complete healing-ver requires at least 3 or 4 years. Lopping flush with the trunk, using a saw, also gave excellent results, and this method is apparently more advisable because it costs less than the previous method, and, in addition, a saw is easy to handle. Lopping with as bill-hook is the least advisable procedure, as it always caused a considerable flow of resin, in spite of the ability of the workman, and it is very difficult, requiring as it does a smart and careful workman.

Coniferous trees should be lopped at the height of the summer heat, for then there is the least flow of resin. But the results were not entirely conclusive as regards this, and the observations should be continued until the wounds are completely healed and definite conclusions can then be drawn.

539 – **The Para Chestnut, or Brazil Nut.** — *Bulletin commercial de la Section des Affaires économiques et commerciales du Ministère des Relations extérieures de la République des Etats-Unis du Brésil*, No. 9, pp. 29-30. Rio de Janeiro, 1919.

The Para chestnut (*Bertholetia excelsa*) is one of the finest trees of the vast forests of the Amazon. It grows slowly and only produces fruit, at 12 years old, when the tree, whose rigid, cylindrical trunk is admirably suited to constructional work, attains a height of 35 to 40 metres. M. J. Huba, formerly Director of the Botanical Museum of Para, has furnished the following information regarding this and other chestnuts of Para :

One of the great resources of the Amazon region is the immense chestnut forests, of which only a small part has been exploited as yet.

The delicious Brazil nut or " Para nut, " of which some 50.000 hectolitres are exported annually to Europe and North America, is the seed of the enormous *Bertholetia excelsa*, which mostly grows in large groups in the forests whick cover the plateaux on both banks of the Amazon and its tributaries.

The large, husked, round fruits ripen during the rainy season (January to March), and fall intact, covering the soil in hundreds, when they are gathered, heaped up and opened with an axe.

The fresh nuts contain much milk, of which the natives make broths, cakes and condiments. When dried, they become oily. Each husk contains from 15 to 20 Brazil nuts. The husks make exellent fuel and can be used for decorations in cabinet work.

Another fairly important products of this tree is the tow that is extracted from the bark.

Chestnut forests occur in large numbers in the Tocantins region, in the Curua and Para valleys, in all the regions watered by the river Trombetas and its tributaries the Cumina, Cuninamirim, Erepecu, and especially on Airamba, in the plain as well as in the extensive plateaux.

The nut, for which there is an ever-increasing demand, as the consumption is spreading everywhere, is a product of which Para possesses very vast areas, as yet uninhabited, but already traversed by several explorers.

Immense regions covered with forests of chestnut trees and rubber are being continually discovered.

The nut takes second place among the exports from the Amazon. Since the war, the exports have decreased, thus interrupting the progressive increase that had previously been shown. The exports of Brasil nuts from 1913 to 1918, inclusive, were as follows:

Year	Metric tons	Paper milreis
1913	4 113	2 464 000
1914	19 117	7 729 000
1915	7 611	3 920 000
1916	9 882	7 175 000
1918	6 450	3 700 000

The nuts are much used in England and the United States, where they are known as Para nuts or Brazil nuts, in confectionery. They can also be used industrially for the preparation of an oil suitable for lubricating delicate machinery.

540 – **The Study of the Physical and Mechanical Properties of Wood in France.** — *Les Bois*, Year XXXIX, No. 4, p. 1. Paris, Feb. 15, 1920.

The French "Administration des Eaux et Forêts" has combined with the technical section of Military Aeronautics in the study of the physical and mechanical properties of wood and, by a circular dated January 8, addressed to the Conservators of Waters and Forests, M. DABAT, director general fo the "Eaux et Forêts" has laid down the methods to be followed in this work; the chief details are given below.

A choice will be made, in the forest estates where the tree occurs under normal conditions of growth, of 3 samples of the wood of each of the trees, the samples to be obtained by the forest officers. The samples will be taken either from trees specially exploited on behalf of the Government, from trees exploited for the Navy, or from certain trees marked out for sale, the provision of these samples to be accurately charged to the cutting.

The tree must be accurately named, and there must be no ambiguity as to its botanical identity. As regards the choice and dispatch of the sample, the following instructions must be followed:

Choice of a typical tree: The sample must be taken from an average tree, typical of the stand, of average girth, with a straight stem, not flat-

tened, without twisted fibre, free from apparent defects, and quite healthy.

Choice of a sample : The sample will consist of a block 1 metre long, cut at from 6 to 10 metres above the ground, and from a part that is not flattened, knotted, or defective.

Marking the sample : On each transverse section, a progressive number, the name of the forest and the number of the Conservation will be marked idelibly (burnt in or painted).

Index card : For each sample a card will be filled up giving the two details above, the name of the tree, and the geological nature of the soil, the method of treatment and any commercial uses of the wood (timber, joinery, etc.).

LIVE STOCK AND BREEDING

541 - **Goring as a Defect of Cattle.** — BIANCHI, G. (R. Scuola Superiore di Veterinaria, Torino), in *Il Coltivatore*, Year 66, No. 9, pp. 243-245. Casale Monferrato, March 30, 1920. HYGIENE

Goring in cattle is a vice and can be a subject of legal action, though in this case the defeet must really belong to the character, i.e., to a serious defect of the central nervous system, and then nothing can be done but to send the animal to be slaughtered. But the author has concluded from his wide experience that this defect is transitory and limited. Without there being a defect in the character, cattle may gore : (1) On account of their youth and because they are not yet broken in ; (2) because the animal has been moved to another shippon (a change in environment has a temporary influence on the character of an animal belonging to any species) ; (3) because of a sudden change of the cow-man ; (4) owing to ill-treatment, even of a passing nature, to disease, or to the administration of a therapeutic or prophylactic diet. Goring is particularly caused by : otitis ; by the presence of foreign matter, parasites, etc., in the auditory canal, on the ala, etc.; by subcutaneous injections in the sides of the neck, etc. To ascertain a temporary or permanent liability to goring, the animal must be watched on several occasions, and the different parts of the head and its organs must be examined.

542 - **Piroplasmosis of Cattle in France.** — PANISSET, L., (Professeur, a l'Ecole vétérinaire de Lyon), in *La Vie agricole et rurale*, Year IX, No. 46, p. 366. Paris, Nov. 15, 1919.

Little is known as to the geographical distribution of piroplasmosis in France and, as yet, the disease is not of great economic importance. It has been reported mainly from Normandy and from the Maubeuge district. A remedy recommended by the author is the intravenous injection of trypanoblue, which has given excellent results in France ; as prevention, the destruction of the ticks by arsenical dips is advised. As there are only a few centres of the disease in France, curative treatment is all that is needed at present.

543 - **Prophylaxis against Bacterial Anthrax by Means of Vaccination, in Morocco.** — MONOD, T. H. and VELU, H., in the *Bulletin de la Société de Pathologie exotique*, Vol. XIII, No. 1, pp. 14-16. Paris, January 14, 1920.

CHAUVEAU'S work has shown that Algerian sheep are resistant to bacterial anthrax of French origin. As Moroccan sheep belong to the same breeds as those of Algiers, it was logical to presume that they too were naturally resistant to the disease originating in France and, *a fortiori*, to the second "pastorian" vaccine. For this reason, vaccination could be carried out by injecting the second "pastorian" vaccine, and an experiment carried out in 1919 on these lines was completely successful. The same method gave equally satisfactory results when applied to the native swine and cattle in Morocco.

Immunity obtained in Morocco with pastorian vaccines does not always last a year, but only 8 or 10 months, possibly less. The duration of immunity should, therefore, be prolonged and maintained either by renewing vaccination at least twice a year, by giving a second injection of the second vaccine in double the dose, or by the subsequent injection of a very slightly attenuated culture.

544 - **The Control of External Parasites of Poultry** (1). — *La Vie agricole et rurale* Vol. XV, No. 47, p. 383, figs. 2. Paris, Nov. 22, 1919.

The destruction of ticks on poultry is, if not difficult, at least a lengthy process. They have to be dealt with one by one, either by pulling them away, which always caused a nasty little wound, by touching them with a brush soaked in paraffin, or by cutting them in two near to the head as possible, using curved scissors.

Of the many methods used to free poultry from harmful vermin, only two are both efficacious and capable of being used by anyone. These methods consist in soaking the feathers with paraffin and using a bath of potassium pentasulphide.

All the so-called insecticidal powders are only effective when freshly prepared, which is rarely the case. They are also defective in that they do not adhere either to feathers or skin, so that the birds get rid of them almost at once. A certain adherence can, however, be obtained if the plumage is wetted with soapy water before applying the powder.

Painting the inner face of the feathers with a small brush soaked with paraffin gives excellent results. Care should be taken not to touch the skin with the paraffin, as it causes a slight irritation.

In more serious cases, in which the poultry are covered with mites, lice and ticks, a more radical treatment is required, which is quite harmless. Potassium pentasulphide is dissolved in boiling water at the rate of 30 gm per litre of water. When the solution has cooled to 30° C, the bird is entirely immersed, except the head, for 1 minute. The solution should not touch the eyes; therefore, the head feathers should be wetted with the finger or a brush. Afterwards, the feathers are drained by pressing them lightly

(1) See *R.*, Sept. 1917, No. 830 and *R.*, April, 1919, No. 495. (*Ed.*)

then the bird is placed on thick litter sheltered from cold, draughts, and sunshine.

Parasites sometimes cause eye troubles, and in this case the eyes are treated with 3 % copper sulphate solution, or by washing the eyes with tepid boricated water, and drops twice a day of silver nitrate solution made up of 0.25 gm., silver nitrate to 100 gm. of distilled water.

545 – **Maintenance and Reproduction with a Diet of Grains and Grain Products.** — HART, E. B. and STEENBOCK, H., in *The Journal of Biological Chemistry*, Vol. XXXIX, No. 2, pp. 209-233, 13 charts. Baltimore, MD. Sept., 1919. ANATOMY AND PHYSIOLOGY

Rats and pigs were used in maintenance experiments on adult animals fed solely with cereal grains (wheat, maize, barley) or their products. For experiments on reproduction, swine were used which had grown up on any normal ration and which were subsequently fed with : (1) Maize alone, barley alone, or oats alone ; (2) a mixture of maize and oats ; (3) maize gluten feed ; (4) maize + oats + middlings + oil meal ; (5) barley + 2.5 % of wheat gluten ; (6) oats + oil meal. All the rations were given with drinking water, and all save the fourth were given with a little common salt at the rate of 1 per cent.

The results, given in charts show that adult animals can be maintained with grains and their products, plus water and salt, for a considerable time, but complete nutrition with these rations is impossible and after a time a decline inevitably sets in.

When such rations are given to sows, they cause the young to die at a rate that increases with the time. The first litter may be fairly successful, but in succeeding litters more and more young are still-born. This bad nutrition is primarily due to inadequate supplies of mineral matter and ultimately to the lack of coarse food and to an inadequate mixture of vitamines. In fact, pigs were successfully reared on a ration consisting of oil meal gluten feed and a suitable mixture of salts. With grains such as oats and barley, the lack of fat-soluble vitamines may be of greater importance than in the case of yellow maize meal.

The birth of dead pigs owing to inadequate nutrition has been previously reported by the authors (HART, E. B., MCCOLLUM, E. V., STEENBOCK, H. and HUMPHREY, G. C., *Research Bulletin* 17, *Wisconsin Experiment Station* 1911 ; *Journal of Agricultural Research*, Vol. X, p. 175, 1917 ; Bull. 187 *Wisconsin Experiment Station*, 1918) for herbivorous animals. A ration of grain, poor roughage, such as cereal straw caused either abortion or the birth of calves before their time or dead. This was mainly due to the lack of mineral matter, especially calcium, since it could be eliminated as with sows, by the addition of calcium salts and common salt.

The function of calcium as a constituent of bone and milk is well known, but, in addition, as CLOWES has shown (*Journal of Physiological Chemistry*, Vol. XX, p. 407, 1916), the constitution of the protoplasm of the intestinal cell-walls is modified by the equilibrium between the salts of sodium and calcium. A diet with insufficient calcium would lead to con-

ditions of the intestinal wall that are specially favourable to the continuous absorption of products of intestinal origin, amongst which there may be bacterial toxins or amines. This finally leads to physiological disturbances, to an abnormal stimulation of the central nervous system, which causes the limbs to tremble and to vasoconstriction and to interference with the normal oxidative processes in the tissues, thus leading to intoxication and asphyxiation.

FEEDS AND FEEDING

546 – **The Use of Woody Matter as Cattle Food.** — SCURTI, F. and DROGOUL, G., in *Le Stazioni sperimentali agrarie italiane*, Vol. LII, Parts 10-12, pp. 490-496. Modena, 1919.

SCURTI and MORBELLI have previously shown (1) that the woody matter in maize stalks separates when submitted to acid hydrolysis under pressure, forming cellulose and sugars, thus changing an almost entirely indigestible fibre into a group of compounds that are valuable as cattle food. The authors have continued this work and, in this article, they have examined wheat straw to see if it can be changed into similar compounds, and if so, to what extent.

Finely ground straw has the following percentage composition: Fats (ether extract), 2.53; crude protein (N × 6.25), 3.64; fibre, 33.76; ash, 4.90; nitrogen-free extract, 55.17; pentosans, 27.30. The straw was heated to 130° C for 2 hours with: (1) Caustic soda in the proportions 1 part straw, 10 of water, and 0.0125 to 0.10 parts of caustic soda; (2) 25 % sulphuric acid solution in the proportion 1 of straw, 10 of water, 0.0125 to 0.25 parts of sulphuric acid; (3) hydrochloric acid in the proportions 1 of straw, 10 of water, 0.020 to 0.125 parts of hydrochloric acid gas; (4) 25 % nitric acid solution in the proportions 1 of straw, 10 of water, 0.025 to 0.15 parts of gaseous nitric acid.

Treatment with caustic soda only partly separates the lignified cellulose, and the final product still contains considerable quantities of pentosans and traces of sugars. Treatment with sulphuric acid liberates up to 66.16 % of cellulose and up to 32.59 % of sugars. Hydrochloric acid is still more active than sulphuric acid, and frees up to 71.30 % of the cellulose and up to 33.02 % of the sugars. Nitric acid yields up to 66.34 % of cellulose and 34.79 % of sugars, and is, as regards the sugar, the most powerful reagent of all.

As cellulose, when isolated from encrusting material and hemicelluloses, does not differ from starch as regards assimilability, wheat straw is an excellent raw material for the preparation of cakes of cellulose paste and sugars.

547 – **The Utilisation of Hevea Seeds as Cattle Food** (2). — FREIRE, D. (Brazilian Consul-General, Liverpool), in *Bulletin commercial de la Section des Affaires économiques du Ministère des Relations extérieures de la République des Etats-Unis du Brésil*, No. 8, p. 48. Rio de Janeiro, 1919.

The shortage of cattle food now being felt in England has led to the examination of other possible foods and, in this respect, experiments have

(1) Summarised in *R.*, July-Sept., 1919, No. 936. (*Ed.*) — (2) As regards the utilisation of rubber seeds for the production of oil and as a cattle food, see *R.*, Dec. 1913, No. 1362; *R.*, March 1914, No. 240; *R.*, Sept., 1918, No. 987; *R.*, July-Sept., 1919, No. 993. (*Ed.*)

shown the superiority of rubber-seed cake. So far, however, no commercial use has been made of the enormous quantities of seeds from the plantations in Malacca, Ceylon, Java, Sumatra, Southern Indies, and Brazil.

Two experiments were made ; in one the cake was given soaked in water to cattle, and in the other, dry. With the exception of 3 animals which showed aversion to the food, the other animals took it greedily. As the cake is naturally dry, on soaking it absorbs its own weight of water and is then more easily ingested by the animal. After being fed for 3 days exclusively on rubber-seed cake, the cattle thus tested showed no signs of disturbance and no effect whatever was observed on the milk.

If Para rubber-seed cake were put on the market in quantity, its rivals made of linseed, husks and residues of kernels, would disappear from the market as they could not face the competition. In fact, rubber-seed cake is practically identical to linseed cake, while Euphorbiaceous seeds such as those of rubber are easier to obtain and manipulate.

Experiments with sheep, however, did not yield the good results obtained with cattle.

It can thus be said that rubber-seed cake constitutes an excellent food for fattening cattle.

It, is hoped in England that the planters in the Far East will co-operate with manufactures in order to organise the production of this cake If this were done, the British colonies would greatly benefit, as a commercial use would have been found for a product previously considered as totally unutilisable, and the same thing would happen in the Amazon valley, which could export large quantities of rubber seed.

548 – **Toxicity of Cacao Shells to Horses.** — Fonzes Diacon (Director of the Laboratory of the 16th. Command), in *Annales des Falsifications et des Fraudes*, Year XIII, Nos. 135-136, pp. 34-35. Paris, January-February, 1920.

Following on the observations of MM. Marchandier and Goujon on the toxicity of cacao shells and on the poisoning of horses observed by them (1), the author brings forward confirmatory evidence based on personal observations dating back to the end of 1918. In fact in October, 1918, at the Engineer's Barracks at Montpellier, horses showed violent excitation following on a daily injection of a mash made of cacao shells, requisitioned from a local chocolate maker (2), and some animals died.

(1) See *R.*, Feb., 1920, No. 217. (*Ed.*)

(2) "Cacao shells are the residue from chocolate making. Zipperer found that the shells constitute 12-18 % of the raw beans, or an average of 15 %. As the addition of the shells to chocolate or cocao is considered to be adulteration, even in the case of cheap grades, the shells cannot be used in this way. So far they have been sold under the name of "cocoa tea", and an attempt has been made to improve their taste by "icing" them. These candied shells are much in favour in eastern Germany ; they have been used also as pharmaceutical specialities and 5 % of cocoa butter can be extracted from them, as well as theobromine. They have been made into cattle cake, selling, according to Zipperer, at 7,50 to 9 fr. a quintal, and of a feeding value between that of good hay and wheat bran" (Chevalier A., *Les Végétaux utiles de l'Afrique tropicale française — Le cacaoyer dans l'Ouest Africain*. Published by Challamel, 17, Rue Jacob, Paris, p. 20). According to the experiments now in question, cacao shells are dangerous to horses, and it would be of interest to ascertain their effect on other domestic animals. (*Ed.*).

The author, called in by the veterinary surgeon at the barracks, suspected the cacao shells, and stopped them being fed. In fact, a mash of cacao shells contains about 700 gm. of shells with 0.7 % of theobromine so that each day some 5 gm. of the alkaloid were being ingested, and horses were very sensitive to it.

STOCK BREEDING

549 – **A Possible Market for Normandy Livestock in the Export of Breeding Animals.** —LIGNIÈRES, J. (Communicated by M. P. Dechambre, remarks by M. Viger), in the *Comptes rendus des séances de l'Académie d'Agriculture de France*, Vol. VI, No. 2, pp. 42-48. Paris, January 14, 1920.

M. DECHAMBRE communicates the text of a lecture delivered before the "Société centrale d'Agriculture de la Seine Inférieure" (France) by Prof. J. LIGNIÈRES, of Buenos-Ayres, on the introduction of French livestock, particularly that from Normandy, into South America, and outlines the programme to be followed for developing the export of Norman breeding animals to South America.

As regards both meat and milk production, there are good reasons why French livestock should find a market in South America. As regards meat, if the South American breeders wish to sell cold-storage meat to French clients, they should cater for their taste, so that meat from French breeds would be quite satisfactory. This would ensure success, for the interests of both parties would be safeguarded; the foreign breeders would profit from the sale of meat in France and the French breeders would profit from the sale of breeding animals.

In his lecture, M. LIGNIÈRES dealt more particularly with Norman cattle as milking animals.

In the Argentine, the dairy industry has developed greatly and is expanding more every year. It would thus appear that the Norman breed is pre-eminently suited to help the Argentine dairy industry to develop still more. But if sufficient exportation to South America is to be maintained, certain rules will have to be strictly observed.

Breeding in Argentina has attained such a degree of development that only the best is required, and French breeders should, therefore, take care not to send any medioere animals that would reflect on the quality of their livestock as a whole. The pedigree of the animals is of prime importance. A well-kept herd book, in which names are admitted only after the closest investigation, is a basis for asking high prices and for gaining the confidence of the foreign buyer. This point is very important, and is a complementary argument to those already enunciated for the proper and extensive organisation of French herd books. To perpetuate and increase the value of the Norman breed as regards milk and butter production, the control associations which carry out scientific selection of the animals should be extended.

Success in exporting also depends on another important point, i. e. the commercial organisation, and it is indispensable that the breeders should form syndicates to direct and control exportation.

But a consideration still remains which, if not perfectly satisfied

suffices in itself to cancel all other efforts, and that is the sanitary question. M. LIGNIERES states that this was the chief cause that lost the Argentine market to Norman cattle and this shows its importance.

In any case, exportation to South America could be establishment on a wide basis and be of great service to French breeders. The objection that French breeders cannot export, so as not to hold back the progress of the reconstitution of French livestock, is a grave error. Trade is the best index of production and exportation can be said to be sign of the quality of a product.

The broad lines of the proposed programme include the more extensive use for herd books, control of the yield, the adaptation of the product to the needs of the importing country, the foundation of syndicates and commercial organisations, and the adoption of sanitary measures that will give the necessary guarantees.

At the conclusion of the communication, M. VIGER pointed on the success attained a few years ago at an international exhibition of agriculture in the Argentine by a fine lot of animals belonging to the Charolais breed, sent by General DE LA GUICHE, a well-known rearer of that breed in France. All the animals were bought and were much appreciated.

550 – **Stock-breeding in Calabria.** — BARTOLUCCI, A., in *L'Italia agricola*, Year 1, No 12, pp. 364-370, 3 fig. Piacenza, December 15, 1919.

At the time of the census on April 6 and 7, 1918, there were in Calabria 10 469 horses, 79 164 asses, 7 958 mules and hinnies, 139 865 cattle, 69 buffaloes, 138 587 pigs, 692 047 sheep, and 441 852 goats.

Compared with the 1908 census there was an increase in the sheep of 46 719 head, in the goats of 80 838 head, a smaller iucrease in the asses of 10 892 and in the pigs of 6 629 head. On the contrary, the other species showed a decrease, especially in the cattle (5 453 head less). The decrease of cattle and increase of sheep and goats furnish a sign of agricultural decline, but this is partly due to temporary factory factors brought about by the war.

Calabrian *cattle* are derived from the Podolian stock and, when not selected, show the defects of that breed, viz., great development of the fore-quarters, poor development of the hind quarters, drooping rump, slight thighs. As compensation, however, they are of good appearance and have good hoofs; they are hardy, vigorous and make good use of their food. In the cereal zone, they are reared on pasture, which is changed every now and then ; on wooded estates in the hill and citrus zones, they are reared under cover, though this is usually scanty.

In the bergamot-orange plantations in the province of Reggio, one or two oxens are reared under cover and during autumn and winter they are fed on the pulp left as a by-product on the extraction of lemons and bergamots. They are often used to drive the numerous machines for lifting water.

Around Paola, excellent beef calves are reared and these, like those of the province of Reggio, are usually crosses between the Simmenthal

and Reggiano breeds. With systematic selection, excellent triple-purpose cattle could be reared, as some cows are heavy milkers, while the oxen are good workers and yield good meat. The average milk production is 12 hectolitres of milk per head per year, and 100 cows produce 60 to 70 calves each year. Crossing with the Gentile Romagnola breed is done only in those places where there is sufficient shelter and food to meet the greater requirements of the crosses obtained. Cattle rearing could be much developed, rather than improved.

The Calabrian breeds of *sheep* originated from the Merino and it is stated that the "mileto-tarentino" sheep is the original stock of the Spanish merino. There are two breeds of Calabrian sheep, the native and the "gentile," of which the former is small, hardy, with a bristling, black and white fleece, a poor milker and a scanty wool producer, whereas the latter derived from the first breed by repeated Merino crosses, is larger and yields finer and more abundant wool.

There are two breeds of goats: native ("nostrana") and Maltese. The former are small, poor milkers, very quiet, and the latter have no horns, have a finer fleece and are better milkers. The he-goats live with the she-goats in the proportion of $\frac{1}{4}$ to $\frac{1}{10}$ of the latter. Sheep and goat rearing is entirely nomadic; it is of great importance in olive plantations.

The pigs, of Celtic origin, constitute two varieties, the "macchiaiuola" (spotted), the more hardy of the two, and which feeds in oak or chestnut woods and in fields where there are plenty of fresh, fleshy roots, and the "casalinga" (domestic), reared on farms and in villages. Crosses with Yorkshire pigs are common in the provinces of Cosenza, Catanzaro and Reggio Calabria.

Horse rearing is falling off more in quality than in point of numbers. Formerly, Calabrian horses were famous as products of Arab and Andalusian horses, but now they represent a great mixture of breeds. In Calabria, the chief direction which horse breeding should take is the production of sadde horses of the oriental type.

The importance of mule and ass breeding in Calabria is due to the great lack of carriage roads. The mules are excellent for military purposes.

The chief product yielded by the cattle and sheep is milk. The cheese industry turns out, even using old methods, famous products such as the following: Marchesato (Cotrone) cheese; "caciocavallo" cheese (1), with fermented curd, which is worked in hot water; "butirro" cheese (2) (made either with pure sheeps' milk, goats' milk, or a mixture of the two), with slightly cooked curd; and "ricotta" (3).

In the littoral zone of large estates and on the plateaux, the large

(1) "Caciocavallo" is a cheese with ropy curd, shaped like a calabash, which are tied in pairs, which are slung "a cavallo" (whence the name) or straddling over a rod to mature. — Cf. Prof. C. Besana, art. *Caseificio*, in *Nuova Enciclopedia Agraria*, Turin, 1908. (*Ed.*)

(2) The "butirro" (= butter) cheese is a shell of cheese filled with butter. (*Ed.*)

(3) "Ricotta" is made by coagulating the albumen in the whey or "serai", then applying slight pressure. (*Ed.*)

livestock establishments have the following numbers of stock: Sheep, 800-1000 head (up to 2000-3000 head in the Cotronese); cattle, 120-150 head; pigs 40-50 sows with 10 boars. The medium-size farms, which are the commonest, have 30-50 cattle, 200-300 sheep, and 15-20 pigs. The small farms have from ½ to ⅓ the number of stock of the medium-size farms, and some have herds of 15-30 goats each for the supply of town milk. Most of the large and medium-sized farms are managed, from the economic point of view, by larger owners or industrialists from the Ionian littoral, with a permanent staff. The small farms are run either on the renting system or the tenant system.

The livestock, reared on the system of changing pasture, spends the winter on the coastal plains and the winter in the Sila on an area of 100.000 hectares, at an altitude of 1900 metres. Formerly, that zone was entirely wooded, but now, especially in the central part, it has mostly been cleared for growing cereals (usually rye), alternating with meadows and potatoes; flax is also grown there. In the summer, over 20 000 cattle are pastured there (only the draught oxen are left on the "marine" or shore pastures), as well as 100 000 sheep, about 5000 horses and a large number of pigs.

551 – **Stock Rearing in French West Africa** (1). — I. Report by M. G. Moussu on a paper by M. J. Derré, "entitled" La production des animaux domestiques en Côte d'Ivoire", in *Comptes rendus des Séances de l'Académie d'Agriculture de France*, Vol. VI, No. 8, pp. 220-222. Paris, February 22, 1910. — Report by M. Dechambre, on two papers by M. Alsigé on the "Situation de l'élevage et disponibilités en viande de l'Afrique Occidentale française" and "La peste bovine dans l'Afrique Occidental Française, 1915-1918", *Ibid.*, pp. 222-224.

As regards livestock, the Ivory Coast colony can be divided into three zones:

(1) A lower, woodland zone, stretching from the 5th to the 7th degree of north latitude, where there are only small herds which have the valuable quality of resistance to the attacks of *Glossina* spp., the carriers of parasitic blood diseases (trypanosomiases). There are only 5000 cattle, 18 000 goats, about 14 000 sheep, on an area of 120 000 sq. km., according to the 1918 census. The cattle are of the lagoons breed, and the sheep of the Fouta-Djallon breed.

(2) A central or savannah zone, occupied by the Baoulé race. It appears that this zone was once prosperous and covered by abundant flocks which, unfortunately, have been decimated by the serious diseases that have affected African livestock for so long. The cattle have a weight of about 200 kg., with an average yield of 50 %, and are always in good condition, because the pastures never dry up und water is never lacking.

(3) A northern or Sudanese zone, which comprises the best breeds of the Ivory Coast, but which is more exposed than the others to the diffu-

(1) As regards livestock in French West Africa, see *R.*, July, 1914, Nos. 449 and 652; *R.*, Feb. 1919, No. 146; *R.* March, 1919, No. 273, For Sudanese wool-bearing sheep and their wool see *R.*, March 1919, No. 376, and *R.*, May, 1919, No. 624. (*Ed.*)

sion of epidemic diseases from the Sudan. There are 30 000-35 000 head ; the sheep and goats, which are very numerous, are derived from the Fouta-Djallon breed.

Horses are rare and very subject to trypanosomiases.

Two great diseases decimate the bigger livestock, i. e., pleuropneumonia and cattle plague. M. Moussu describes the history of these diseases and shows the extent of the damage they have done, He thinks that great impetus would be given to stock rearing if protective measures and a good sanitary service were put into action against the two above-mentioned diseases and against the various trypanosomiases. Detailed information is given regarding the situation in each district and on the methods for obtaining a general improvement by the selection of breeding animals and the foundation of farm schools, particularly required to teach the diets suitable for each period of the year. Food resources are not wanting, as products such as rice, maize, manioc, yams, etc. — all products that can be made use of in one form or another — are available. Any expenditure thus incurred would not only be easily recovered, but would represent a source of wealth for the future.

II. — During the terrible epidemic of cattle plague that affected French West Africa from 1915 to 1918, M. Aldigé obtained valuable information as to the progress of the disease and suitable sanitary measures for its control. The disease first started in the Niger and upper Niger regions, then spead to Upper Dahomey, Upper Senegal, and Niger, and then to the coastal colonies, Senegal, Mauritania, French Guinea, Ivory Coast, Dahomey, and Togo. It was carried from 1915 to 1918 usually on the caravan routes, by trading cattle going a long distance. The death rate was influenced by various factors (breeds, regions), but it was always high with young animals fed by the mother, and these mostly died. The mortality varied from 10 to 60 % of the adults, according to the breeds and regions ; the humpless small n'dama breed suffered most, while the Moorish zebu was the most resistant.

Sanitary action was supplemented by the use of serum, although great difficulties were met with in preparing large quantities owing to the lack of the necessary materials and trained men. All the same, the results obtained are in favour of active measures against cattle plague. Methods of defence consist in isolation and the creation of immune zones by the use of bile, immunising blood or serum.

The gravity of the epidemic that raged from 1915 to 1918 has shown that French West Africa, should protect itself as completely as possible against all contagious diseases, which, in fact, while severely affecting the number of colonial livestock, considerably reduce the number available for the home country. An epizooty such as that which has just deprived French West Africa of at least 2 million head of cattle should never be seen again. In addition, account should be taken of an important factor which is the very considerable diminution of the young animals which leads to decreased stock-rearing and to the prolongation over several years of the period during which a small number of cattle is available.

In spite of the losses during 1915 to 1918, cattle rearing remains of prime importance to French West Africa. The reorganisation of the Service of Animal Husbandry and Epizooties will give certain assurance for the security of stock rearing and marketing. The growing production leaves 500 000 animals suitable for killing each year, and as the local consumption is not more than 250 000 head, an equal number will be available for exportation.

552 - **The Lippizza Breed of Horses from Istria.** — *Giornale d'Ippologia*, Year XXXII, No. 6, p. 2; No. 16, p. 3. Pisa, March 31, August 21, 1919. HORSES

The famous breed of Lippizza horses belonged to the former Austrian crown. It derives its name from the estate on which it was bred, and which is situated 13 km. to the NW of Trieste, on the Carso plateau, at an average elevation of some 400 metres. The land is hilly, of purely carsic nature ; one part is under pasture, and the rest grows various trees. The climate is generally mild, the winter temperature varying between 8 to 22° C, while that of summer is never above 38° C in the shade and is always tempered by the sea breeze. In winter, the icy and violent "bora" wind often blows, but it causes no serious harm to the animals, which suffer more from the humid sirocco.

The Lippizza breed was founded in 1480 by Duke Charles of Styria, who imported 27 mares and 6 fine stallions from Spain. Later, some Italian mares of the "Marinette" breed, a breed of the Polesina which has now vanished, were imported. The modern Lippizza horse is the product of these two breeds, although the blood has been renewed several times by the introduction of Andalusian and oriental pure-breds. The last few years, two distinct families were reared at Lippizza, the old Italo-Spanish Lippizza breed and the Siglavi family, obtained by crossing pure-bred Lippizza mares with pure-bred Arabs. The blood was renewed again recently by the introduction of mares of oriental origin. In 1918, the stud consisted of some 80 mares and 5 stallions.

The Lippizza horses are from 1.37 to 1.65 metres high ; the expressive head has a slightly flattened nasal line, recalling its Spanish ancestry ; the neck is well set on the shoulders and the mane is long and thick. The shoulder, often too heavy, is a little defective as regards its setting and length; the chest is wide and deep and the withers are rather low; the back is straight, and the well-sprung back is wide and strong ; the cruppers are rounded and muscular ; the tail, well attached and provided with hair, is carried elegantly ; the limbs are well set a good shape and movement, and the tendons are well marked and clean. The strong, wide hocks are free from defects and the hoofs are excellent and well shaped.

The coat is generally grey. The animals are agile, strong very intelligent and of slow maturity (they are only full grown at 7 years), but of extraordinary longevity and resistance to fatigue up to a great age. Defects of the bones are almost unknown in these horses.

At Lippizza, the breeding season begins towards the middle of De-

cember and lasts to the end of April, so that the foals arrive in autumn, when the pasture is richest.

After weaning and after becoming accustomed to the halter, the foals born at Lippizza were taken to the rearing depot at Prestanegg, near Postumia, where a total of 108 to 180 foals were reared. After the first few weeks of life, the foals were given oats, at first in small quantities, then in amounts increasing according to the growth. Weaned foals were given oats even before they were put out to pasture. At one year of age, all animals of the Lippizza breed were branded under the left cheek with the letter *L*. Entires chosen for stud work were sent to Lippizza after 3 years at Prestanegg and were broken in, and at 4 years old they were sent to the Riding School of the Viennese Court to have their temper and strength tried. If these proved satisfactory, they were sent back to Lippizza to act as stallions, but if unsatisfactory, they were gelded and sent to Kadrub to be broken in and trained. Three-year old fillies suitable for use as brood mares were sent back to Lippizza, and, after a trial of their intrinsic qualities lasting a year, it was decided whether they were to be mounted or not. The rejected fillies, were then sent back to Prestanegg and, like the geldings of the same age, broken in at Kadrub.

When war broke out between Italy and Austria in 1915, all the Lippizza stud was taken to Vienna and later on almost wholly sold to private persons. In 1919, the Italian Government obtained over 100 Lippizza mares, stallions and colts, which will be used to reconstitute the ancient breed.

553 – **Improvement of Horse Rearing in Libia.** — Manetti, C., in *L'Agricoltura coloniale*, Year XIV, Nos 2-3, pp. 90-115. Florence, Feb.-March, 1920.

True horse breeding does not exist in Libia, as the few rare groups, of horses found there belong to rich families from the coastal towns, or to some Arab chiefs from the interior, especially the Orfella tribe. Camels are exclusively used for transport on the caravan routes, the ass is used for total work, and the horse, especially in the furthermost oases, is entirely missing However, the country should be particularly suited to the production of horses, for the best Arab horses are produced in the poorest and most arid countries, and there was a time when horse rearing was of great importance in Libia. The lack of fodder is not irremediable, because the pastures which have been ruined by continuous neglect and excessive pasturing by sheep and goats can be improved, and even water for drinking places can often be obtained from the subsoil. The great relapse in horse rearing in Libia is due particularly to social and economic reasons, such as the prohibition by Turkey of the export of horses, so as to obtain supplies more easily.

The Libian horse is of the oriental breed, it is of medium size (a little below 1.50 metres high), with a weight varying between 300-400 kg.; wither high, back short, croppers very hollow, chest narrow, limbs and hoofs strong. Balance is nearly always defective, owing to bad method of rearing, the colts being shod and put to work too soon ; they are made to walk always at a trot, which gives them their bad shape, especially their

hollow cruppers ; an unsuitable system of turning them out to grass is used, etc. The predominating colour of the coat is light grey. Like the other Berber horses, the Libian horse runs and jumps well, and resists fatigue and privations ; it is particularly suited to military purposes.

In order to improve the existing stock of horses, it will first be necessary to select the local horses ; afterwards, it will be feasible to introduce improving blood in the shape of Berber horses from the adjoining countries, especially from southern Tunis. With present conditions, it is not yet the moment to make use of Arab or Sardinian-Arab stallions and still less of stallions belonging to improved and exacting European breeds.

The author thinks that two distinct Institutes should be established in Tripolitania and Cyrenaica ; one experimental, for investigating problems of rearing, acclimatisation, etc., and one executive, for propaganda work, and which would have special care of stallions for remount purposes, while taking charge of the practical improvement of the horses of the region by conciliating the needs and wishes of the breeders with national interest. The second Institute would also deal with the organisation of fairs, markets, syndicates of breeders mutual assurance societies against the loss of stock, hygiene, and sanitary administration. It would also control the breeding of mares belonging to colonial troops in its area.

Horse rearing should be specially directed towards the production of the war horse.

554 – **The Duration of Gestation in Mares of the Lippizza Breed.** — STAFFE, A., in *Mitteilungen der landwirtschaftlichen Lehrkanzeln der Hochschule für Bodenkultur in Wien*, Vol. III, Pt. 3, pp. 547-594, 2 diagrams, bibliography of 33 titles. Vienna, December 20, 1918.

It cannot be denied that the duration of gestation has a certain significance from the standpoint of selection, seeing, that, as a rule, colts that have been procreated in a shorter time become better horses when they grow up.

The duration varies according to the breed, for early maturity breeds (western) have a shorter gestation period than breeds that mature later (eastern) Embryonic and postembryonic development thus have an analogous duration. The size of the breed, however, does not appear to be related to the duration of gestation.

Gestation is practically always longer for the birth of colts than for fillies, because the female embryo has a more active temperament, so that parturition begins earlier, especially because the female embryo grows more rapidly. Similarly, the postembryonic development of the female ends earlier.

In the same breed (kladrub Spanish compared with Lippizza mares, the duration of the foetal life of white colts and fillies is from 0.2 to 3.0 days shorter than that of brown or jet-black colts. The greater richness in dark pigment and the greater length of gestation represent original qualities, so that it is natural that the two characters should occur together.

The author has used the Lippizza stud book to work out the following periods of gestation :

Breed	Locality where reared	Period to which the data relate	Average length of gestation days	
			For the birth of males	For the birth of females
Lippizza	Lippizza	1828–1842	337.10	333.00
		1860–1870	338.30	337.69
		1906–1916	342.55	338.31
»	Radantz	1906–1916	338.00	338.30
Kladrub Spanish white	Kladrub	1877–1906	346.32	343.80
Kladrub Spanish jet-black.	Kladrub	1877–1906	346.76	344.00
Kladrub Spanish	Hochwald	1894–1903	338.18	337.00
Haflinger	Brioni	1911–1916	324.18	322.90
Huzulen	Radantz	1905–1916	324.00	339.00
Mountain Bosnian	Goražde	1906–1913	335.14	331.62
Shetland Pony	Berlin	1913–1916	409	

Under southern climates, the gestation period is shorter than in northern climates, but the removal of animals to a northern climate may lead to a shortinlng of the gestation period, owing to richer food.

The weight of colts at birth increases with the duration of foetal life.

Opinions so far expressed regarding the duration of gestation in primiparous are not in agreement. Many researches have been carried out on : (1) comparison, for 30 mothers, of the duration of the first gestation with the following ones ; (3) comparison of the duration of the first gestation with that of each successive gestation which gave a product of the same sex as in the first ; (3) comparison for 100 mothers, of the duration of the first and fifth generation ; for another 100 mothers, comparison of the duration of the first gestation on the one hand, of the 2nd, 10th and 1st. on the other. The results of these researches apparently show that, owing to the greater sexual potency of the young mother, the first-born have a shorter foetal life.

According to researches made at Kladrub and Mezöhegyes, mares covered by a jackass have a gestation longer than the normal, mainly because a longer time is required for the fusion and division of the cells on account of the difference in shape and number between the chromosomes. As a rule, twin embryos are born or abort, but there are exceptions.

Researches on the duration of gestation, made by the author at Lippizza, Radantz, Gorazde, and by Von Wellmann at Mezöhegyes and Fozaras, show that at the beginning of the parturition period, the length of gestation is shorter, even by 22 days, than at the end of that period. The opinion that temperature, pasturage, and external influences in general are the cause of this behaviour, is not tenable. The cause is rather the greater or lesser sexual potency of the mares at the time of serving, and at the beginning and end of the " heat " period. Greater sexual potency leads to a stronger development of the foetus.

The duration of different gestations in the same mare often shows but slight differences ; it thus becomes a true physiological character.

The typical duration of gestation is transmitted hereditarily as much by the mother as, in a latent state, by the father. A long gestation is dominant, in the Mendelian sense, compared with the average gestation and the short one, and the average gestation is dominant compared with the short gestation, as has been shown by the segregation of these characters in the 2nd generation. The process of heredity can be explained genotypically by the hypothesis of a factor **K** which expresses the tendency to a short gestation and of 2 homomerous factors of inhibition **H** and **I**.

555 – **The Increase in Weight of a Belgian Colt.** — Rossi, in *Giornale d'Ippologia*, Year XXXII, Nos. 11-12, p. 2. Pisa, June 16-30, 1919.

The weight of an animal is almost always related to its growth, and the growth is related to its earliness of maturity, which shows the interest attaching to the following figures giving the average increase in weight of 2 pure-bred Belgian colts, born and bred in Italy :

Colt No. I :	Weight at birth	75	kg.
	Weight at 10 months	423	»
	Average daily increase during the first 300 days of life	1.16	»
	Weight at 26 months	715	»
	Average daily increase between the first and second year	0.60	»
Colt No. II :	Weight at birth	71	kg.
	Weight at 8 months	330	»
	Average daily increase during the first 240 days of life	1.09	»
	Weight at 24 months	700	»
	Average daily increase between the first and second year	0.70	»

556 – **The Andalusian Breed of Cattle.** — Ulmansky, S., in *Mitteilungen der landwirtschaftlichen Lehrkanzeln der Hochschule für Bodenkultur*, Vol. III, Part 3, pp. 457-546, Bibliography of 48 titles, 10 tables, 13 plates. Vienna, Dec., 1918.

The author went to Spain to study the various Spanish breeds of domestic animals, especially the cattle. In the present work he deals with the Andalusian breed of cattle, the most widely distributed and most important Spanish breed. He deals with the distribution, feeding and rearing conditions, the colour of the skin and the coat (there are 3 varieties : reddish-brown, black, and white), conformation, aptitudes (firstly work, secondly meat ; the breed is no use for milk production), the structure of the cranium, the origin, hypotheses as to the place occupied by Andalusian cattle in the zootechnical system, breeds with analogies to the Andalusian breed, and its history. The conclusions arrived at are given below.

The type of cattle distributed over more than three-fourths of Spain, the Andalusian breed (which also includes the " corrida " bulls), belongs to the species *Bos primigenius* and not to the brachycephalic type as has hitherto been supposed. The Andalusian ox even belongs to the purest and finest *Bos primigenius* type that has yet been studied. With its three varieties, which are identical except as regards coat colour, the Andalusian ox is the direct descendant of the aurochs and, to be more exact, of a variety of aurochs which is distinguished by having horns with a bony core.

From various points of view, characters of *Bos trochoceros* Meyer are to be found in the Andalusian ox.

There is nothing in Spanish history that lends colour to the theory that the type of the Andalusian breed was introduced in a domesticated state into the country. On the contrary all the evidence points to the conclusion that it originated from domestication of the indigenous wild ox, since it is autochthonous and is still to be found there in a pure state and almost half wild.

Apparently, the Andulusian breed is closely related to some of the some of the primitive English (Devons, Welsh,) Italian (Val di Chiana) and South American (Franquero) breeds.

557 - **The Illawarra Cattle of New South Wales.**— Suter, P. H., in *The Journal of the Department of Agriculture of South Australia*, Vol. XXII, No. 5, pp. 378-381, figs. 2 Adelaide, December, 1918.

The breed of cattle known as Illawarra cattle, South Coast Shorthorns or Majors is a first-class dairy breed. It owes its first name to the fact that it was improved and fixed in the Illawarra district of New South Wales. It is a product of crosses between the Shorthorn, Ayrshire, Devons and longhorned roan cattle introduced from Ireland. Amongst the foundation stock that contributed greatly to its improvement, the author mentions a Shorthorn bull named Major and one of its descendants, Commodore. At present, the Illawarra breed closely resembles an ideal type of dairy Shorthorn.

558 - **Dairy Cattle in Southern China.**— Levine, C. O. (Canton Christian College), in *The Philippine Journal of Science*, Vol. XV, No. 1, pp. 91-104, 1 plate. Manila, July, 1919.

The only areas in Kwangtung where dairying has made any progress are the districts round Canton and Hongkong. Three species of dairy cattle — European breeds of cattle, buffaloes and zebus — are bred there. The dairies around these two towns utilise approximately 1600 cows, including about 1200 of European origin, imported from England, the United States, or Australia, and include the Shorthorn, Holstein, Ayrshire, Jersey and Guernsey breeds. The breed present in greatest numbers is the Shorthorn, especially the white variety. Pure bred animals are few in number, but crosses between European breeds and the native zebus are sometimes found. The European breeds are never allowed to graze for all the pastures are infested with ticks that transmit piroplasmosis, which is always fatal to imported cows, whereas their progeny, once acclimatised, soon become immune to the fever.

The buffaloes are mainly reared as draught and beef animals. The females which are milked do less work. There are no special breeds of dairy buffaloes. A milking cow fed on grass and grain will give milk for 8 to 12 months, the quantity produced per day varying between 3 to 15 lb., with an average for the whole lactation period of about 4.5 lb. a day. The small quantity is compensated for by its richness, as it contains 3 to 4 times as much fat as the milk of the European cow.

The native cow of southern China is a common Eastern variety of the humped species (*Bos indicus*). The hump is slight and is only 6 to 8 in., high in the bulls and less in the cows. The coat varies in colour from reddish yellow to brown-black; white coats are not found and spotted ones are rare. The tongue, nostrils and teats are back. The bulls weigh from 800 to 1000 lb., the cows from 600 to 800 lb. The milk is richer than that of European breeds, but it is not as rich as buffalo milk. The amount of milk given is about as much or a little less, than that given by buffalo cows; they are very docile and very few are milked. The humped species are meat and draught animals; the hind quarters are full and deep and there is another deep layer of flesh on the back and cruppers.

The following are analytical data obtained by the author relating to milk:

	European cow.	Native buffalo cow.	Native zebu cow.
Fat	3.80	12.60	8.00
Protein	3.23	6.04	—
Sugar	5.96	3.70	—
Ash	0.82	0.86	—
Moisture	86.20	76.80	—
Total dry matter	**13.90**	**23.90**	—

A series of tables includes: The complete analysis of the milk of the buffalo cow and of the cow of European origin; the fat content during several phases of the entire lactation period for 14 individual buffaloes, and detailed somatic measurements of 12 buffalo cows. The average fat content during the whole lactation period of each buffalo cow varied from 9.65 to 15.60 %.

559 - **An Experiment in the Rearing of Calves on Whey and Meals.**— Ministry of Agriculture and Fisheries, pp. 12 + 2 pl. London, April, 1919.

The food value of whey is usually considered to be too low to allow its use as a basal food for calves and for this reason it is given to pigs. But, in parts of England where cheese-making is of great importance, whey has been used to a certain extent in feeding calves, either given to calves kept at pasture or as the fleetings that rise to the surface when whey is heated. As information regarding this was scanty, the question was examined experimentally on behalf of the Ministry of Agriculture and Fisheries in the spring of 1918 by University College, Reading, under the direction of M. S. PENNINGTON.

The average composition of 1 litre of milk and 1 litre of whey was as follows:

	Whole milk	Whey
	gm.	gm.
Moisture	900	955
Fat	40	4
Protein	35	9
Sugar	49	52
Ash	8	7

Thus, to bring the food value of 10 litres of whey up to that of 10 litres of milk, 360 gm. of fat (fat or oil) and 260 gm. of albuminoids must be added as well as phosphates. There is practically only one food that is a good complement to whey, and that is linseed, 1 kg. of which furnishes 0.35 kg. of oil and 0.25 kg. of albuminoids. Cod-liver meal, the by-product obtained in the preparation of cod-liver oil, is also suitable as it contains 44.1 % of oil and 36.5 % of albuminoids, but it cannot always be found on the market.

In other experiments, the lack of fat in the whey compared with skim milk was compensated for, not by adding oil, but by adding a mixture of oil and starch or some other carbohydrate. Expressing the food value of milk and whey as starch equivalents, the deficit in food value of 10 litres of whey compared with 10 litres of milk is practically 1 kg. of starch.

In any case, a little precipitated bone phosphate is added to neutralise the acidity of the whey.

It was found that the foods caused no digestive troubles in the animals, and after investigating the question of digestibility, the following rations were adopted as complements to skim milk:

(1) Linseed meal + linseed cake (3 : 2).
(2) Linseed meal + bean meal + fish meal (3 : 3 : 1).
(3) Linseed meal + fish meal (2 : 1).
(4) Linseed meal + coconut cake (1 : 1).
(5) Bean meal + linseed cake (5 : 4).
(6) Linseed meal + fish meal + crushed oats (3 : 1 : 3).

With No. 1, the calves gave an average increase in weight of 3633 gm. per head per week from the 7th to 17th week; with No. 2, the increase was 4218 gm. The four other rations were fed to calves from the 2nd to the 17th. week, and gave respectively the following average increases in live weight, in gm. per head per week:

(1) For the 15 weeks of the experiment, 2289, 3030, 3193, and 2762 gm.

(2) For the last 10 weeks of the experiment, 3207, 3361, 3633, and 3329 gm.

In each experiment, the complementary ration was given at the rate of 1 kg. per 10 litres of milk, while the calves were given hay ad lib. and were finally put out to grass.

The whey was heated to 37° C, and 30 gm. of precipitated bone phosphate was added to every 10 litres of whey.

These complementary rations were found to be nearly equal in value, although that containing bean meal showed a slight superiority.

The results show that after 4 weeks calves can be given hay ad lib. and, when they can eat it, linseed cake or a mixture of coconut cake and gluten feed is added beginning with 60 gm. per head and going up to 240 gm.

The system of feeding should be as follows :

From birth to 2 weeks : colostrum followed by the first milk produced.

From 2 to 4 weeks : After the second week, the whole milk is gradually replaced by whey and the above-mentioned mixtures in the right proportions. The quantity of substitutes is increased each day and the milk decreased until, at 4 weeks, the calf receives 4.5 litres of whey, 450 gm. of the complementary ration and no milk. At first the mixture should be mixed with the milk, but as soon as the calves can eat it alone, it must by given separately, and the whey to which precipitated bone phosphate has been added must be given as a luke-warm drink.

From 4 to 5 weeks : Continue the ration of 4.5 litres of whey and 450 gm. of the complementary ration per head per day and give now hay ad lib.

From 6 to 7 weeks : The above-mentioned ration is increased by giving linseed cake or a mixture of linseed cake, coconut cake and gluten feed at the rate of 60 gm. per day given after the morning meal, the quantity being gradually increased to 240 gm. per head per day.

From 8 to 9 weeks : Increase the amount of whey given daily to 6.80 litres and the supplementary ration to 680 gm. per head per day.

From 10 to 12 weeks : Give the whole ration.

From 13 to 14 weeks : Gradually reduce the supplementary ration from 680 gm. to 450 gm. per head per day, while giving the same amounts of the other food.

From 15 to 16 weeks : Reduce the whey to 4.5 litres and the supplementary ration to 230 gm. per day, so that the calves are given 4.5 litres of whey, 230 gm. of the supplementary ration, 170 gm. of cake (or cake mixture), and hay ad lib.

After the 17th week : If the calves can be put out to grass or if succulent fodder is available, no whey or supplementary ration need be given at the end of the 17th week, but, in this case, the cake given must be increased to 230 gm. per head per day.

If, while whey is being fed to the calves, it produces much wind, this can be avoided by adding a little precipitated carbonate of lime to the whey.

560 – **Swine-Feeding Investigations in Kansas (1918-1919)** — Mc CAMPBELL, C. W., FERRIN, E. F. and WINCHESTER, H. B., in the *Kansas Agricultural Experiment Station*, Circular 78, pp. 1-8. Topeka, October, 1919. PIGS

I. SELF-FEEDING VERSUS HAND FEEDING. — Experiments intended to demonstrate the value of free feeding compared with hand feeding in fattening 75 lb. pigs and to show at the same time the amount of tankage required to supplement a maize ration.

Method. — Twenty pigs of uniform age, weight, quality and condition, were divided into 2 groups of 10 each and placed in dry lots. The first group fed from a self feeder, provided with a compartment for shelled maize and another for tankage ; the second group was given, twice a day, as much as they could eat of a mixture of 10 parts of shelled maize and 1 part of tankage. Both groups were watered twice daly. The experiment lasted 100 days. The initial weight was taken as the average of the first three days and the final weight as the average of the last 3 days. The animals were bought at the market, and were sold there at the end of the experiment ; all the expenses due to fattening and to the experiment were calculated.

TABLE I. — *Self feeding versus hand feeding* (100 *day experiment*).

Results. — The results, given in Table I, show that the first group ate more maize and less tankage than the second ; the quantity of tankage needed to obtain the best results was reduced to 5 % of the maize. The more economical increase of weight is probably due to the fact that

with self feeding the animals took the food more often and made a better use of it.

II. — SEMI-SOLID BUTTERMILK VERSUS TANKAGE, LINSEED MEAL PEANUT CAKE AND ALFALFA HAY AS THE SOLE SUPPLEMENTARY SOURCE OF PROTEIN MAIZE FOR FATTENING SWINE. — The special aim of this experiment was to study the food value of commercial semi-solid buttermilk in fattening swine on maize as a protein supplement.

Method. — Fifty pigs, bought at the market, and of uniform weight, quality and general condition, were divided into 5 lots of 10 each. All the lots were hand fed and the rations of each lot were calculated so that all the feeds cost the same

Prices of foods : — Maize, $1.58 per bushel ; tankage, $ 100 per ton ; semisolid buttermilk, $ 80 per ton ; linseed meal, $60 per ton ; peanut cake, $60 per ton ; alfalfa hay, $25 per ton.

Results. — The results, given in Table II, show that the cost of an increase in live weight of 100 lb. was lowest for the group fed on tankage and

highest for the group fed on semi-solid buttermilk, as sole supplementary sources of protein for pigs of an average weight of 80 lb.

Consequently, Lot I gained most in weight and Lot II gained least. There was not a great difference in the final degree of fattening attained by Lots I, II and IV, whilst Lot III, fed on linseed meal, attained a less finished state of fattening, which may be due to the fact that the food was not very attractive to the animals. With alfalfa, the pigs grew better, but the final fattening was less satisfactory, which considerably diminished the unit price of the animals fattened in this way, though the unit price of the gain in weight with alfalfa was slightly higher than the price obtained with tankage. Further experiments will be carried out to see if, by combining the foods thus tested singly in different ways, it is possible to obtain more economical results in fattening.

III. — Rearing pigs born in autumn. — Experiments made with the object of collecting data regarding the rearing of pigs in autumn, especially from an economic standpoint.

Method. — Thirty young pigs were divided into 6 lots of 5 each. They were all born in autumn, and over half at the end of October. All the lots were fed on shelled maize, with the following supplementary albuminoids :— lot I tankage; lot IV linseed meal; lot II tankage and middlings; lot V linseed meal and middlings; lot III tankage, middlings, and semisolid buttermilk; lot VI linseed cake, middlings and semisolid

Valuation of feeds: shelled maize $1.54 per bus.; tankage $5.50 per 100 lb.; linseed meal $3.25 per 100 lb.; semisolid buttermilk $4 per 100 lb.; wheat middlings $2.25 per 100 lb.

buttermilk. Self-feeders were used, but she semisolid buttermilk was given ad lib. twice a day.

Results. — The results, given in Table III, show that the greatest increase in weight was in every case obtained with tankage. The addition of middlings had a useful effect. The addition of buttermilk for lots III and IV gave greater gains in weight and a greater margin of profit. Further, the experiment showed that, for successful winter rearing, farrowing, should not take place later than September so that the animals will be sufficiently grown when the first winter cold appears. There should be a warm, dry shelter, with good straw litter free from dust, to avoid any risk of the young pigs catching pneumonia. During the coldest periods, the gain in live weight was very small.

The experiments will be continued next winter, in view of a subsequent study of the different combinations of feeds.

POULTRY

561 - **The Physiological Relationship between Fecundity and the Natural Yellow Pigmentation of Certain Breeds of Fowls.** — PALMER, L. S. and KEMPSTER, H. L., in *The Journal of Biological Chemistry*, Vol. XXXIX, No. 2, pp. 313-330, 2 plates. Baltimore, M. D., September, 1919.

It has long been observed that there is a close relation exists between the quantity of yellow pigment visible on the shanks, ear lobes and beaks of certain breeds of fowls such as European (Leghorn) or American origin (Plymouth Rocks, Wyandottes, Rhode Island Red) and the number of eggs previously laid by them. It has been suggested that this correlation should be used in selecting good laying hens (1).

According to BARROWS (*Maine Agricultural Experiment Station Bulletin* 232, p. 237, 1914), the yellow colour of fowl's legs is due to deposits of yellow fat in the Malpighian layer of the epidermis : and PALMER (*Journal of Biological Chemistry*, Vol. XXIII, p. 261, 1915) has shown the existence of a physiological relationship between the xanthophyll of plants and the lipochrome in egg yolk, blood serum, and in the body fat of the hen. But the researches described in the present paper show that the fading of the yellow pigmentation in the visible parts of the skin due to fecundity is not due to the removal of pigmented fat from these parts and its passage to the egg-yolk, but to the deviation of the secretion of xanthophyll, which takes place in the egg and not in the parts mentioned ; these parts gradually lose their colour, partly by oxidation, and partly by the wearing away of small pieces of the skin.

Full grown cockerels were fed on a ration free from carotinoids (white maize + skim milk) ; after a certain time, a food containing carotinoids (substitution of red or yellow maize for the white maize, or by adding grass) was added to the ration, and the effect of these foods on the disappearance or reappearance of pigmentation and on the activity of egg formation was studied. The egg yolk, blood plasma, and sub-epidermal fat were colorimetrically examined and the skin of the claws, coloured deep

(1) See *R.* June, 1915, No. 631 ; *R.* Feb., 1916, No. 207 ; *R.*, April, 1918, No. 448. (*Ed.*)

yellow, was studied histologically. The following conclusions were arrived at :—

The fading of the yellow pigmentation from the ear lobes, beak, shanks, etc., in Leghorn and American fowls during fecundity is due to the fact that fecundity deflects the normal path of xanthophyll excretion from these parts of the epidermis to the egg yolk. The xanthophyll deposited in these epidermal parts gradually disappears on account of the natural physiological change in the structure of the skin. The thicker the epidermis, the slower the disappearance of xanthophyll.

The xanthophyll in the above-mentioned parts of the epidermis is mainly present in a granular form, associated with little or no fat. It occurs especially in the Malpighian net-work, but it also exists in the subcutaneous blood-capillaries.

Xanthophyll cannot be restored to the fowl's skin as long as fecundity lasts, no matter what excess of pigment the fowl is made to ingest. The adipose tissue does not store xanthophyll derived from the food during the period of egg formation, even when rations rich in xanthophyll are given, because the pigment is entirely excreted in the egg yolk.

The fading of the colour of the ear lobes, beak and shanks of fowls resulting from egg laying is an index of *continuous* fecundity only and not of *heavy egg laying* The yellow colour of those parts just after the end of the laying season indicates either intermittent fecundity or a more or less recent loss of fecundity, during a period sufficiently long for the xanthophyll to be restored to the body.

562 – **The Effects of Castration on Cockerels.**— Laurie, D. F., in the *Journal of Agriculture of South Australia*, Vol. XXII, No. 1, pp. 40,-43. Adelaide, August, 1918.

The question of the regeneration of the testicles after castration has aroused great interest of late, as the fact is related to problems of genetics. For this reason, the author again took up some experiments that he had carried out some 30 years ago.

It was then believed that, to destroy the testicle, it was sufficient to extirpate it by crushing it and removing as much as possible of its contents, but later it was realised that the capsule might be left intact and thus regenerate the secretive tissue and the seminal ducts of the testicle. The author found this occurred on several occasions. He has repeated old experiments with young White Leghorns, Rhode Island Reds, Barred Plymouth Rocks, from which one or both testicles were removed, either completely or only in the intracapsular portion. Only in the first case did the cocks assume the characters of normal capons, i. e., lengthening of the legs, longer and more abundant plumage, head of a neuter appearance. When one testicle is completely removed, the second regenerates itself and takes on a normal size and shape, that is sometimes normal or almost normal, sometimes different and smaller. When the two testicles are only crushed, they regenerate themselves ; the external sexual characters remain unchanged. This constitutes a marked difference between birds and mammals.

The author enters into considerations on the internal organs of secretion and the influence of hormones.

The testicles, like the ovaries, are organs of internal secretion and elaborate substances similar to enzymes, which have a profound effect on growth, general development, characters, etc., and, in certain cases, a reciprocal action takes place between them. The removal, loss, or modification of one or the other of them has serious effects on the organism, or principally on another organ of internal secretion.

As regards the testicles, total extirpation, including the removal of the capsule, deprives the bird of the organs that elaborate the hormones which influence the development of the secondary sexual characters in the male. In the case of ovariotomy, the phenomenon is more complex: in certain cases, the removal of the ovary (there is only one in the fowl) leads to the assumption of male characters and the formation of a testicle. The ovary owes its origin to the DE GRAFI follicles and it is obvious that these regenerate themselves normally, at least in the fowl. It is supposed that this is due to the development of the aptitude for egg-laying in the fowl. There is also reason for believing that selection plays a part as regards the aptitude for sperm formation of the male sexual glands regenerated in poultry. Partial removal of the ovary may lead to degeneration. The destruction of the ovary suppresses the organ which produces the hormones that prevent the appearance of the secondary sexual characters of the male, and these appear for that reason. These facts confirm the supposition that "feminality" is a supernumerary character to "masculinity", and, if the former is removed, the second remains; it is apparently a case of two Mendelian characters.

Other internal secretory organs, such as the thyroid, thymus, pituitary and pineal glands, are influenced by castration.

563 – **Feeding Experiments with Pullets and Hens.** — PHILIPS, A. G., in *Purdue University, Agricultural Experiment Station, Bulletin* No. 218, pp. 20 + 40 figs.; Lafayette, Ind. August, 1918 and No. 227, pp. 3-28 + 7 figs., 1919.

I. — *The Value of Skim Milk and Meat Scraps for White Plymouth Rocks.* — The results are reported of feeding experiments with pullets and with hens. The experiments with pullets, conducted for 3 consecutive years beginning in December 1914 included an annual series of 3 pens, each receiving a mixed grain ration made up of maize and wheat, 10 lbs each, and oats 5 lbs with a dry mash consisting of 5 lbs each of bran and shorts. In addition to this allowance one pen received 50 lbs of skim milk and another pen 3.5 lbs of meat scraps, these quantities furnishing approximately the same amount of protein. During the winter the maize was increased to 15 lbs, the wheat reduced to 5 lbs, and in the fall 1 lb of oil meal was added. Grit, oyster shell and ground bone were always available as was also water, except in the skim milk pen. When not on range the birds were fed with mangels. The skim milk was fed in an open pan and the meat scrap was mixed with the mash. There were 30 pullets in each flock.

The consumption of feed of the meat scraps pen was 97.63 lbs of feed per fowl at a cost of $1.69; the no-meat-food pen was 83.24 lbs at a cost of

$1.37 and of the skim-milk pen 201.82 lbs at a cost of $1.79. Of the feed consumed in the latter pen, 115.74 lbs was milk.

All birds tended to consume a similar amount of grains and mash regardless of whether they were good or poor layers. It was the addition of skim-milk or meat scraps to the ration that increased the efficiency of the grain.

The cost of feeding a Plymouth Rock pullet on a good ration averaged about $1.75 for the year 1916 but during 1917 this cost increased to nearly $2.50.

It cost an average of $0.155 to produce a dozen eggs in the skim-milk pen, $0.152 in the meat scraps 'pen and $0.275 in the check pen. It cost less to feed a pullet when no skim-milk or meat scraps was fed, but it cost more to produce a dozen eggs.

The amount of dry matter required to produce 1 lb. of eggs in the skim-milk pen was 4,9 lbs; in the meat scraps pen was 5.14 lbs and in the no-meat-food pen was 9.57 lbs.

The egg production averaged 140.2 eggs per pullet for the skim-milk, pen, 135.9 eggs per pullet for the meat scraps pen, and 61.2 eggs per pullet for the check pen.

All birds tended to lay the most eggs in or about the month of April whether well or poorly fed ; and whether good or poor layers.

The profit over feed in the skim -milk pen was $1.59 ; in the meat scraps pen, $1.62 ; and in the no-meat-food pen, $0.05.

The feeding value of skim-milk for Plymouth Rock pullets was $1.60 per 100 lbs and of meat scraps was $20.03 per 100 lbs.

The meat scraps pen produced better fertility but not as good hatching power as the skim-milk pen. Birds receiving neither skim-milk nor meat scraps produced eggs of the best fertility (1).

A Plymouth Rock pullet produced about 27 lbs of fowl's dung in a year at night.

The method of feeding had no influence on the health or mortality of the flock. At the close of the first and second years of the experiments above described the check pens were also retained and continued on their ration another year. This was done to determine whether or not the poor egg production in the check pens has been due to the lack of animal protein or to poor laying powers in the particular birds. The results secured in this test the following conclusions:

Under normal conditions, hens consume about as much food as pullets. Hens that have been starved for animal protein as pullets, increase their consumption of everything as hens, when fed with milk in abundance. It costs but slightly less to feed a hen than a pullet.

When fowls are supplied with sufficient animal protein all their lives they normally lay less eggs as hens than as pullets. Fowls that do not receive sufficient animal protein as pullets, lay poorly, but when given skim-milk as hens they lay as many if not more, eggs than pullets

(1) See also *R.* Febr. 1920, No. 238. (*Ed.*)

normally produce. A fowl's egg capacity cannot be judged by the number of eggs she lays unless she receives a normal ration. The no meat-food pullets molt early and are in full new feather by October. When skim-milk is added to their ration in November, they respond quickly by laying more winter eggs as hens than any fowls did as pullets.

Early molting indicates poor laying, but it may not indicate poor laying ability. Hens not fed with milk as pullets produce more income and profit than those fed as hens, compared with milk-fed pullets. Hens seemed to produce better fertility than pullets, but showed little improvement as regards hatching capacity

II. — *Feeding Experiments with Leghorns.* — Feeding experiments with White Leghorn pullets during the years 1914-15 to 1917-18, and studies of the influence of confinement on egg production made in 1913-14 with hens and in 1914-15 with pullets are reported. The grain and mash rations and general treatment were the same as in the contemporaneous Plymouth Rock experiments above reported. Three pens of 30 birds each were used in each of the six experiments.

The first two experiments were duplicates. One pen received 5.3 lbs of cottonseed meal mixed with the mash, another had 50 lbs of buttermilk to drink for each 35 lbs of standard grain and mash, while the third received 50 lbs of buttermilk and a double allowance of grain, making the ratio of grain to mash 5 : 1.

The other two feeding experiments also duplicated each other. One pen was fed with only the standard grain and mash, while the second and third received in addition 3.5 lbs of meat scraps and 3 lbs of tankage, respectively. It was estimated that equal amounts of animal protein would be furnished to the latter pens. The main results of the feeding experiments are summarized in the following table :

Annual Egg and Feed Records per Bird of Leghorn Pullets during Feeding Experiments.

Averages of first and second experiments				Average of third and fourth			
Addition to Standard Ration	Number of eggs	Grain and mash consumed	Total feed per lb of eggs	Addition to Standard Ration	Number of eggs	Grain and mash consumed	Total feed per lb of eggs
Cottonseed meal . .	55.7	50.2	9.05	Meat scrap	179.1	70.5	3.77
Buttermilk	168.9	63.1	7.77 *	Tankage	183.5	71.3	3.60
Buttermilk and grain	137.9	64.2	7.25 *	None.	59.5	62.0	9.32

* Liquid buttermilk computed at 10 per cent. of its weight.

Cottonseed meal is considered practically worthless as a protein concentrate for egg production The egg records of the birds receiving it were especially low during the winter.

In the experiments on the influence of confinement it was found that birds kept housed continuously averaged 112.3 eggs per year, those with access to a small yard (10 by 80 ft) 124.4 eggs, and those with access to free range (130 by 160 ft) 128.75 eggs.

564 – **Feeding Laying Hens without Wheat or Middlings, in New Zealand.** — Brown-F. C., in *The Journal of Agriculture, New Zealand Department of Agriculture, Industries and Commerce*, Vol. XVI, No 6 pp. 331-333. Wellington, June, 1918.

A series of feeding trials of laying hens was undertaken at the Poultry Station at Milton (New Zealand) from 1915 to 1918. The fowls belonged to both light (White and Brown Leghorns) and heavy (Black Orpington and White Plymouth Rock) breeds. The question was whether heavy egg laying could be obtained without feeding either wheat or middlings. The results agreed well and were affirmative. In a year a group of White Leghorns and another of Brown Leghorns which were given wheat and middlings, laid, respectively, 239 and 243 eggs per bird. Two similar group, which were not given these foods, laid 238 and 241 eggs per bird, respectively. The following year, the averages for the four groups, always kept on the same rations, were 159, 179, 175, and 201.

In experiments with the heavy breeds, the groups that received no wheat or middlings actually laid more eggs than the groups that did have those foods, as will be seen from the following Table :

Feeding tests with heavy breeds (*May* 1, 1917-*April* 30, 1918).

Breed	Average No. of eggs per head per year	Food consumed		kg
Black Orpington .	200	Middlings	Mash	320
		Bran		92
		Maize flour		120
White Rock . . .	198	Meat and bone meal		33
		Meat and bone meal (given separately)		45
		Wheat		464
		Alfalfa meal	Mash	250
		Bran		90
Black Orpington .	210	Maize meal		100
		Crushed oats		120
White Rock . . .	216	Meat meal		34
		Meat meal (given separately)		50
		Whole oats		440

Alfalfa meal, bran and oats are thus excellent substitutes for wheat and middlings for heavy and table breeds.

The food was given in the following way: In the morning, the mash was made with hot water, as much being given as could be consumed without waste, and, in addition, meat meal placed in a separate trough. At noon, the green food, especially chopped alfalfa, was distributed ; in winter, it was replaced by turnips or mangels given whole. At night, the grain was strewn on the straw litter. Gravel, coarse sand, broken oyster shells and clean water were always available for the hens.

565 - **Bee-keeping in Morocco.** — JEAMMET, in *L'Apiculteur*, Year 63, No. 9, pp. 217-219. Paris, September, 1919. BEE-KEEPING

On account of its climate and rich flora, Morocco is well suited to bee-keeping. The Doukkala region, situated in the district behind Mogador, Souss and the Middle Atlas, produce a great deal of honey, but as the natives consume large amounts, the production does not cover the demand.

" Mobile " bee-keeping either does not exist in Morocco, or is represented by a few isolated experiments, but fixed bee-keeping, practised by the natives in a primitive way, has attained a high degree of development. The average yield per hive is very high, i. e., 50 to 70 kg. per annum.

The extraction of the native honey is often not cleanly, the bees and nest being crushed together and put into recipients of doubtful cleanliness, so that the honey sometimes has an unpleasant taste. But honey extracted under cleanly conditions with a centrifuge is exquisite and of flavour varying with the district where it is gathered, on account of the diversity of the flora. The honey gathered from Euphorbiaceae by the bees should be noted, as it burns the throat, and though of fine appearance, nothing suggests its taste.

The Moroccan honey flora includes the following plants, the best being printed in *italics* :— orange, mandarin, lemon, cedrate, quince, pear, peach, apple, cherry, apricot, *almond*, pomegranate, locust-tree, eucalyptus, ilex, cork-oak, *Judas tree*, " arganier ", *Myoporum*, beans, pea, chick-pea, all cereals, flax, wild or cultivated leguminosae, " minette ", sainfoin, clover, lucerne, mustard, *Spanish broom*, wild Resedaceae, corn poppy, poppy, mallow, honeysuckle, fennel, cactus, aloes, olive, palm, many Labiatae, *rosemary*, *lavender*, sage, *thyme*, *hyssop*, balm, mint, marjoram, etc.

566 - **Bee-keeping as a Source of Profit to the French Tropical Colonies.** — *L'Agronomie Coloniale, Bulletin mensuels du Jardin Colonial*, New Series, Year IV, 1919-1920, No. 27, pp. 86-87. Paris, November-December, 1919.

Up to the present, little interest has been shown in bee-keeping in the tropical colonies of France, though it would not take much to increase largely the production of honey and especially of wax, which finds a ready, sale at prices which would allow its transport from distant regions. It would be of a certain value in various areas of central Africa, especially in the interior of Equatorial Africa, the Middle Congo and Oubanghi.

According to the export statistics of the French colonies for 1917 (*L'Agronomie Coloniale*, No. 22, Jan.-Feb. 1919), the total exports of wax for that year amounted to 787 207 kg., of which Madagascar supplied 502 633 kg., French Guinea 213 800 kg., and Senegal 63 093 kg.

Wild bees are found everywhere, and abundantly in tropical regions and, though their products are the subject of trade in certain districts, there is no true apiculture, as the natives simply collect the honey and wax in the brush, often by destroying the colonies of bees.

The following information, furnished by the French Chargé d'Affaires at Haiti, shows the profit that could be derived from rational bee-keeping, which has given excellent results in Haiti where, owing to the high prices reached by honey during the war, bee-keeping has considerably developed of late.

An apiary does not cost much and gives comparatively large returns. The cost of maintenance is estimated at 8 fr. per hive per year. Exact information on this question has been collected, as an enterprise of this nature might be well suited to certain types of mutilated soldier. France imports fairly large amounts of honey from Haiti and St. Domingo, and apparently it would be worth while to establish the industry in the French colonies. Bee-keeping, in fact, gives better results in the tropics, as the bees can work all the year round.

During March, 1919, Haiti exported 38 308 kg. of honey (16 014 kg. to the United States and 22 294 kg. to France), as well as 1333 kg. of wax, worth 5720 fr., all of which went to the United States. The capital required in Haiti to establish an apiary of 100 hives is estimated at 5200 fr. The Haitian bee-keepers usually prefer "Italian" bees, as they are more active and resistant. A hive produces from 50 to 65 litres of honey and 0.9 kg. of wax per annum and will, it is estimated, yield a profit that represents about 40 % of the capital invested.

567 – **Italian Honey.** — *Bollettino di Notizie Commerciali, Ministero dell'Industria, del Commercio del Lavoro*, Year XLV, No. 18-19, p. 593. Rome, October, 1919.

Much Italian honey was exported before the war; during the war, it has been more widely used and has found a variety of new applications. It partly replaced sugar as human food and as an industrial material and, consequently, the export not only stopped, but honey was imported from the United States. Wholesale prices which, until 1914, averaged about 80 to 90 fr. per quintal, rose to 950 fr. in 1918, and some sales were even made at 1200 fr., a price that was not reached on any foreign market. At the end of the 1918-1919 season, the average price was 600 fr. a quintal, but a drop is expected for the 1919-1920 season, as American honey is being offered at 350 fr. per quintal, free of customs, on Italian railway wagon. Spain is also offering white honey extracted by the centrifugal process. This price should be compared with that of white crystallized sugar, which is 455 fr. per quintal; usually, the price of honey is a third less than that of sugar.

Italian honey, extracted by the centrifugal process, is the best in the world. Its indisputable superiority is mainly due to the flora, according to which there is some variation in the quality of the honey. Honey from localities planted with citrus plants has a pleasant taste, and is fragrant and slightly acid; that from acacias and limes is exquisite and white

that from Labiatae is aromatic and clear yellow ; that from woods is not very tasty ; that from heather and buck-wheat is brownish-red, sweet, but not of very good quality ; that from tree nectar is dark brown and ordinary ; that from the arbutus, which is gathered in Sardinia, is bitter ; that from sulla lacks fragrance, but is much liked for its sweet taste and because it is liquid and limpid in summer, solid and white as snow in winter. The nectar or pollen bearing plants, or both, of the Italian flora are very numerous and chiefly belong to the following families : Aurantiaceae, Rosaceae, Leguminosae, Labiatae, Boraginaceae, Cucurbitaceae, Amentaceae, Polygonaceae, and Compositae.

FARM ENGINEERING

AGRICULTURAL MACHINERY AND IMPLEMENTS

568 – **Foundation of an Experimental Institute of Agricultural Mechanics in Italy.** — *Gazzetta ufficiale del Regno d'Italia*, No. 79, pp. 9966. Rome, April, 3 1920.

The decree-law No. 325 of March 7, 1920, authorised the Italian Government to establish, in co-operation with public and private institutions, an experimental institute of agricultural mechanics, in order to help national agriculture and industry. The institute will be declared as of public utility and will be supervised by the Ministry of Agriculture.

The object of the institute will be to help, by means of researches, control, and advice, in securing improvements in agricultural machinery and plant, and to help in diffusing their use under the conditions most suitable for the different regions of Italy.

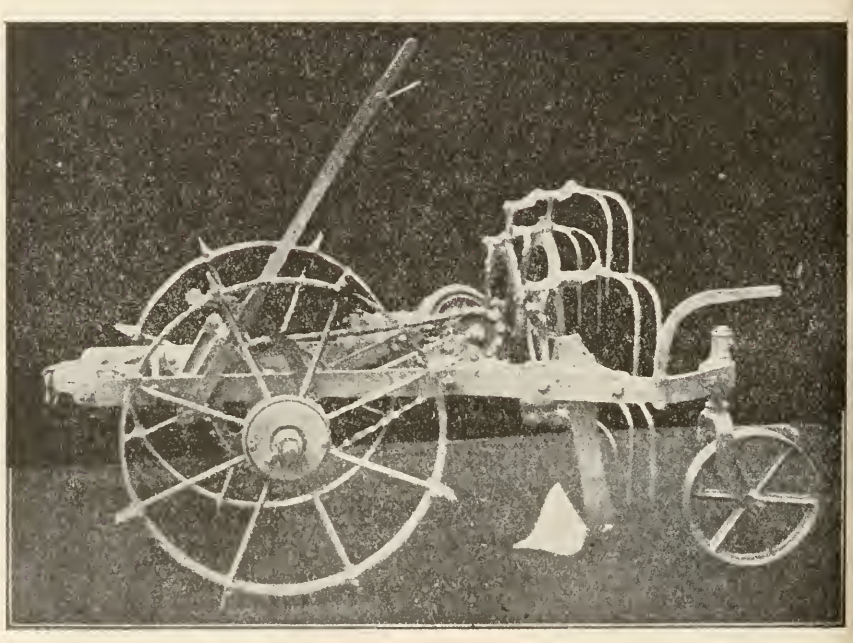
The institute will be most active at places and in periods where agricultural work is in progress, and will be centred at the Higher School of Agriculture, Milan.

The State will contribute 100 000 lire towards the foundation of the institute and will pay 50 000 lire a year towards its upkeep. The contributions of public and private institutions towards the cost of founding and maintaining the institute will be fixed by special agreements, and a series of Rules for the working of the institute will be drawn up at a later date.

569 – **Bamlett's Potato Digger.** — *The Implement and Machiney Review*, Vol. 45, No. 540, pp. 1793-1797, fig. London, April 1, 1920.

The Bamlett's Potato Digger is fitted with a special hitch, and can be drawn by horses-attached by means of whippletrees — or by a tractor, and it is claimed that the elimination of a pole or shaft means great economy in space at the headlands. Clean digging is produced by the special arrangement and construction of the tines, which, as nearly as possible, reproduce the action of the hand-fork. In this way the potatoes are " combed out " and not dragged with great lumps of earth. Nor are they scattered about, but laid with evenness and regularity. The tines are at the rear of the mechanism, and are long and curved. The tine-bearings are not near where the tines enter the earth but carried well away from the dirt and dust. Should the tines strike hard rock, stone, or, any other severe obstacle, they are so arranged as to have an elasticity of mo-

ment which lifts them clear of such bodies. This flexibility is due to the fact that the tines have not got a rigid centre, so that a certain amount of play is allowed. The digger is chain-driven, and the speed of the tines can be changed by the introduction of different size sprocket-wheels. In this way the speed of digging can be regulated to suit the speed of the horses or the nature of the soil, or both.



BAMBLETT'S Potato Digger.

The bevil-gear is mounted in a one-piece bracket. The chain is of the enclosed joint-pin type. A renewable unbreakable steel point is fitted to the share. By the use of a long lever the share can be adjusted while the digger is travelling, and the same lever also raises or lowers the share and line of draft when turning at the headlands. A constant level of work can be maintained by the manipulation of the rear wheel, which acts in much the same manner as a friction wheel at the rear of the sole plate of a plough.

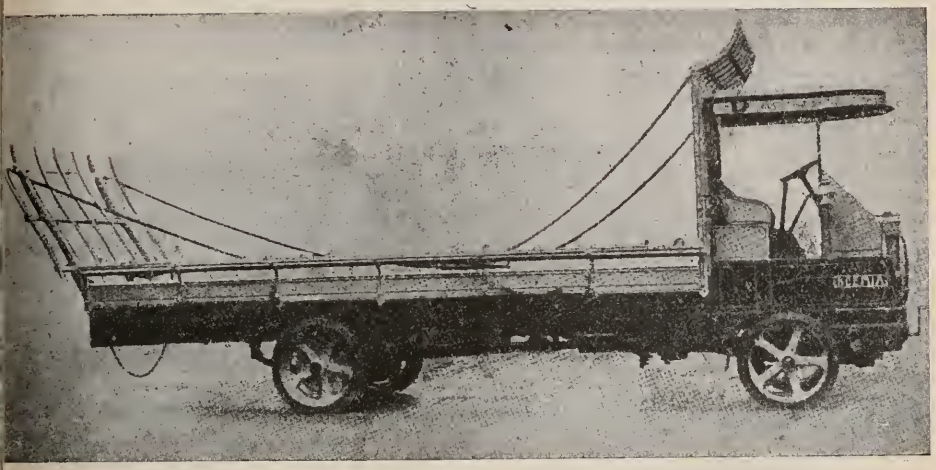
570 – **Motor Hay Waggon.** — DESSAISAIX, R., in the *Journal d'Agriculture pratique*, Year LXXXIV, New Series, Vol. 33, 1920, Vol. I., Nos. 12-13, pp. 220-221. Paris, March 18-25, 1920.

The use of motor lorries for the transport of forage presents certain difficulties on account of the large volume that has to be loaded on the lorry so as to get a sufficient load to justify the purchase of the vehicle, which entails a considerable sum.

To do this, the "Société SCEMIA" makes use of the C. G. O. SCHNEIDER body, which has been developed jointly by the "Cie. générale des omnibus de Paris" and the "Etablissements SCHNEIDER et Cie." of Creusot.

The 5-ton chassis has a 34 H.P., 4-cylinder engine (bore, 0.105 mm.; stroke, 0.150 mm.; 1000 revs. per minute).

The wheels, in cast steel, like those of the Paris bus, can take 900 × 140 solid tyres on the front wheels and double 950 × 160 tyres on the



Motor lorry.

back wheels. The speeds are 6800, 12 800, and 22 600 metres per hour and the reverse runs at 5 000 metres per hour.

The chassis itself is 7 m. long, 2.25 m. wide, and weighs 3000 kg. The special body shown in the Figure is mounted on the chassis. There are low side-racks and the floor is 6 m. long and 2.25 m. wide; in front, a curved rack protects the roof over the driver, and at the back another rack limits the load to about 4 tons of hay or straw.

571 – **Safety Butteris for Paring Horses' Hoofs.** — AYME, H., in the *Journal d'Agriculture pratique*, Year LXXXIV, 1920, Vol. I, No. 9, pp. 172-173, 1 fig. Paris, Feb., 26, 1920.

This is a very useful little device and should replace the btuteris that has been used since time immemorial by farriers for paring horses' hoofs.

The very primitive tool now used has serious disadvantages and must be used most carefully or it is liable to wound either the horse or the man holding the horse's foot; it is difficult to sharpen, as the raised edges make it impossible to sharpen the inner part with the ordinary grindstone. Struck by these defects, M. ETIENNE, a farrier of Isle-sur-Sorgue (Vaucluse)

has invented a butteris which has the following advantages over the old type : The blade can be removed and can therefore be sharpened quite easily on any grindstone ; the front part of the tool is rounded so that there is no danger of wounding either the man holding the foot, or the horse being shod. The blade acts like a plane with the difference that the bevelled side is on top. The blade is held in a bronze frame and is fixed in place by a screw nut tightened up by a wing bolt ; as the screw stips in a groove, the blade can be adjusted to project more or less, and, in spite of wear, the cutting edge can always be kept in the right place.

ETIENNE Safety Butteris.

VARIOUS. — *Canada :* 196813 Machine for cutting hedges.

FARM BUILDING

573 – **Silo Construction.** — SHEDD. C. K. and FOSTER, W. A., in *Agricultural Experiment Station, Iowa State College of Agriculture and the Mechanic Arts, Bulletin* No. 189, pp. 94-148, 43 figs. Ames, Iowa, April 1919.

The construction of silos has been for many years one of the principal lines of investigation followed by the Agricultural Engineering Section of the Iowa Agricultural Experiment Station. Results have been published in the following bulletins : No. 100, July, 1908, revised and republished July, 1909 ; No. 117, June 1910, by J. B. DAVIDSON and M. L. KING and No. 141, June, 1913, by J. B. DAVIDSON. This new bulletin No. 189 is a revision of Bulletin No. 141 incorporating data of additional value obtained since 1913. No special type of silo is recommended. With reference to the water tank placed on top of a masonry silo, it has been found that treatment of the inner surface of the tank with a coating of asphalt followed by cement plastering apparently prevents leakage.

RURAL ECONOMICS

RURAL ECONOMICS

574 – **Results of Agricultural Book-keeping by Double Entry by the Pestalozzi Institution near Birr, Argovie, Switzerland, for the Year 1918-1919.** — ZAUGG, F., in the *Annuaire agricole de la Suisse*, Year 20, Part 3, pp. 295-315. Lucerne, 1919.

GENERAL. — The Pestalozzi-du Neuhof Institution keeps the books of its farm on the double-entry system, which is controlled by the " Bureau de Comptabilité Agricole du Secrétariat des Paysans Suisses. From the results obtained in 1918-19, compared with those of previous years, which are dealt with in the present report, an opinion can be formed as to the utility of agricultural book-keeping by double entry and the inexhaustible mine of information and suggestions which it provides. The accounts are kept by the Agricultural Accounting Bureau of the Secretariat, using as a basis, weekly and monthly reports sent by the Director of Neuhof to the Secretariat which, for its part, keeps and closes the accounts.

RESULTS. — *A*) *Fundamental Accounts* : (1) *Capital.* — The farm capital of Neuhof has changed little since 1916, when stock was taken :

(1) *Cf.* Results of farm accounts kept by double entry, in *Annuaire agricole de la Suisse*, Pt. 1, 1918, pp. 41-118. Berne, 1918.

the beginning of the year for the first time. Certain difficulties were met with at the time, since certain groups of capital had to be estimated in the absence of data that could serve as a basis, as, for example, the heading, *advances to crops*. These difficulties, however, disappeared in the following years and each element of capital found its own place in the balance sheet. Table I shows the composition of the capital of the Neuhof farm, and will help to explain the data relating to the year 1918-19, compared with previous years. In Table II, the capital invested in the Neuhof farm is compared with the average of other farms of the same area which are included in the researches of the " Sécrétariat des Paysans Suisses " on agricultural profit. Neuhof has an area of 36.78 hectares and thus belongs to the category of large farms (over 30 hectares).

The average active capital, on the average, of the 50 farms that constituted this group in the researches of the Secretariat was 3 889 fr. per hectare, or about 1 000 fr. less than in the case of Neuhof. The Neuhof estate cost more than the average set down as the inventory value of farms of the same area which send their accounts to the Secretariat. However the percentage ratio of the different groups to the total active capital is more favourable in the case of Neuhof than in the case of the group with wich it is compared in Table II, owing to the fact that less active capital is engaged in the estate than in the working capital. The profit yielded by the farm seems as if there is no reason that it should be unfavourably influenced by the extent of the capital invested per hectare.

It has already been stated that little change has taken place in the Neuhof estate capital since 1916, and, in addition, there have been no important changes in the capital invested in building.

The *advances to crops*, however, which amounted to 10 738 fr. in the spring of 1916, increased to 28 146 fr. in the spring of 1919. This heavy increase is primarily due to the extension of arable land. The constant intensification of exploitation also plays a part and the increased cost of fertilisers, seeds, and labour are contributory factors.

The farm capital reflects the high prices of livestock, and from 33 747.2 fr. (including the horses, pigs, and poultry) on May 1, 1916, increased to 38 404 fr. in the spring of 1919, in spite of the reduction in the number of livestock that had to be brought about in 1916. As regards this, the producing cows were not valued at current market prices, but on the basis of an average value, corresponding to that conferred upon them by the ultimate destination.

(2) *Movement of cash.* — The total receipts and expenses were as follows:

Years	Total receipts Fr.	Total expenses Fr.
1916–1917	39 749.50	39 093.50
1917–1918	45 699.40	33 160.48
1918–1919	59 583.25	37 472.04

The distribution of the receipts was as follows:

Receipts from	1916-1917 Fr.	1917-1918 Fr.	1918-1919 Fr.
ivestock	25 686.80	26 991.10	37 822.65
rops	13 076.20	16 899.50	20 718.55
arious	986.50	1 808.80	1 042.05

The receipts of Neuhof in 1919 were considerably increased by the rops. The receipts from potatoes alone were 15 240.50 fr. in 1918-1919, gainst 7 271.80 fr. in 1916-1917.

A large part of the expenses is due to the purchase of fodder and other ood as is shown below:

	1916-1917 Fr.	1917-1918 Fr.	1918-1919 Fr.
oncentrated food	10 275.60	5 326.48	4 591.13
ermented hay or hay still standing	8 555.35	6 089.45	8 135.18
ost of summering	871.00	—	—

Renting land from the ANGLIKER Foundation had the effect of distinctly mproving, in the last few seasons, the production of the hay required for fairly large herd.

B) Distribution of expenses: (1) *Household expenses.* — The household xpenses, due to food for those living at Neuhof were as follows:

Years	Total Fr.	At the rate of 1 day's food per man Fr.
916–1917	24 516.84	2.05
917–1918	32 135.71	2.69
918–1919	39 645.18	2.98 (aproximately)

According to the researches of the "Secrétariat des paysans," as egards numerous farms under its control, the household expenses were is follows:

Years	Number of farms	Francs
1916	295	1.93
1917	347	2.35
1918	400	2.85

(2) *Labour costs.* — These were distributed in the following way:

Items	1916-1917 Fr.	1917-1918 Fr.	1918-1919 Fr.
Wages in cash	4 926.60	3 886.05	4 412.01
Maintenance	3 117.50	3 467.00	3 923.54
Payment in kind	—	—	64.00
Rent of buildings and instruments	200.00	190.00	220.00
Director	1 200.00	1 200.00	1 200.00
Pupils	1 150.00	3 091.50	3 074.10
Various	83.20	424.09	227.65
Total cost of labour	**10 677.30**	**12 258.64**	**13 121.30**
Labour cost per hectare	286.28	276.20	291.91
Cost of labour per working hour	06.46	0.659	0.87

The distribution of the labour between some of the chief branches of the farm is shown below:

Years	Crops		Fodder crops		Livestock	
	Hours	% of hours worked	Hours	% of hours worked	Hours	% of hours worked
1916–1917	3 860	15.86	1 820	7.48	9 720	39.94
1917–1918	4 851	19.42	2 121	8.49	9 410	37.67
1918–1919	2 704	12.65	3 490	16.33	9 238	43.25

The increase in the hours worked in fodder crops is due to their extension, whereas the decrease in the hours worked in crops is largely due to good weather, owing to which the work was done quickly.

(3) *New distributions, purchase and amortisation of buildings, instruments, and machinery.* — The rent of buildings is made up of the following items:

	1916-1917 Fr.	1917-1919 Fr.	1918-1919 Fr.
Current repairs	641.01	896.76	1 378.45
Amortisation	500.00	500.00	500.00
Interest	1 976.00	2 044.00	2 024.00
Taxes	190.75	148.67	136.24
Total rent of buildings	**3 307.76**	**3 589.43**	**4 238.69**
Per 100 fr. of capital in buildings	**6.70**	**7.02**	**8.38**

The capital distribution per 100 fr. of deadstock is as follows :

	1916–1917 Fr.	1917–1918 Fr.	1918–1919 Fr.
Current distribution	10.46	17.01	26.24
Amortisation	10.55	12.02	15.36
Interest	4.50	4.50	4.50
Fire insurance	0.05	0.11	0.23
Taxes	0.39	0.29	0.27
Rent of buildings	4.25	4.17	5.21
Total : rent of deadstock	**30.20**	**38.10**	**51.81**

The increased expenses due to deadstock in the last season is accounted for by high labour costs and costly material.

(4) *Use of concentrates.* — The control of the movement of the natural products can be used to find the exact use of the concentrated foods. The consumption of feeding stuffs is expressed in kg. of *starch value* and in francs in the appended table :

	1916–1917	1917–1918	1918–1919
	kg starch value	kg starch value	kg starch value
Foods bought	24 969	11 785	5 273
Foods produced	10 460	12 256	16 919
Total food consumed	35 429	24 041	22 192
	fr.	fr.	fr.
Foods bought	10 545	6 946	6 169
Foods produced	8 803	11 275	19 514
Total food consumed	19 348	18 221	25 683

The prices entered per 100 kg. of starch value rose from 54.61 fr. for the total consumption in 1916-17, to 75.80 fr. in 1917-18, and 115.20 fr. in 1918-19, so that food per day per 1 000 kg. live weight increased from 2.57 fr. in 1916-17 to 3.55 fr. in 1918-19, whilst the quantity of starch value fed, fell from 4.68 kg. per 1 000 kg. live weight in 1916-17 to 3.08 kg. in 1918-19. The bought foods rose in price by 160 % and those produced by 37 %. The quantity of concentrated food distributed, expressed in absolute figures, has decreased by 37 % since 1916.

The number of normal days of maintenance was 7 555 in 1916 and only 7 225 in 1918. The consequences of decreasing the starch value given as concentrated foods in 1918 (3.08 kg. per normal day, against 4.68 kg. in 1916) are shown in the production of milk, meat, and manure.

(5) *Purchases of standing hay and aftermath and of fermented hay.* —

Expressed in starch values, the purchases of these foods were 29 727 kg. in 1916-17, 14 944 kg. in 1917-18, and 16 295 kg. in 1918-19. The cost of production increased from 12.32 fr. and 11.53 fr. in 1916-17 to 21.83 fr. and 23.67 fr. in 1918-19, respectively for dry fodder bought as standing hay and aftermath, and for fermented hay.

(6) *Purchases of fertilisers.* — The quantities of fertilisers used were as follows :

	1916-1917	1917-1918	1918-1919
Basic slag	7 325 kg.	4 740 kg.	100 kg.
Superphosphates (18 %)	550	—	—
Potash salts (30 %)	2 750	5 600	2 850
Nitrate of lime	1 650	2 080	1 000
Lime	—	100	6 300
Total costs	**1 959,20 fr.**	**2 348,66 fr.**	**1 105,52 fr.**

The quantities bought, decreased owing to difficulties in obtaining supplies of fertilisers.

C) Yield accounts : *Winter wheat.* — The area under winter wheat more than doubled during the three years. The chief results regarding this crop are given in Table III. The 1916 crop was very poor,

TABLE III. — *Wheat.*

		1916-17	1917-18	1918-19
Area cultivated	ares	**390**	**451.4**	**825.39**
Crop, total grain	kg.	4 150	7 360	16 400

Crop, total straw	»	17 740	17 500	51 700
Crop, straw per hectare	»	4 549	3 877	6 263
Total crop in starch values	»	5 514	7 823	19 301
» » » » » per hectare	»	1 414	1 733	2 338
Cost of producing 100 kg. : —				
Seed wheat	fr.	48.06	41.35	36.43
Wheat	»	41.59	37.28	32.84
Straw	»	8.32	5.24	6.16
Market price per 100 kg. : —				
Seed wheat	»	61.00	71.00	71.00
Wheat	»	—	64.00	64.00
Straw	»	9.00	9.00	12.00
Total net yield	»	1 278.08	3 479.42	9 388.96
Net yield per hectare	»	327.70	770.80	1 137.60
Net yield per 100 fr. of capital	»	7.12	19.78	25.71

that of 1917 below the average and that of 1918 satisfactory (about 20 quintals per hectare). The last of the years under review had the lowest costs of production, with about 34.50 fr. per quintal. The sale price varied between 64 and 71 fr., so that a good profit per quintal was made. The interest on the capital invested in the wheat crop was 25.7 %, against 7.1 % and 19.8 % for the two previous years.

The author remarks that the decline in wheat growing that took place before the war was largely due to the excessively low price of this cereals, which was selling at 18 to 20 fr. per quintal, whereas the cost of production varied between 34 to 35 fr. per quintal.

(2) *Oats.* — The cost of production for oats in 1918 was 36.65 fr. per quintal, and 40.20 fr. for seed oats, for 20.25 quintals per hectare, compared with 17.72 and 21.94 fr. in 1916 with a production of 19.27 quintals per hectare.

The cost of manuring was very high and overloaded the oat account ; the other items were also very high. The interest on the capital invested in the oat crop was 21.7 % in 1918, against 23.38 % in 1916.

(3) *Spring barley.* — The production cost of spring barley was 45.38 fr. in 1918, for 21.22 quintals per hectare, against 22.68 fr.in 1916, with a yield of 14.34 quintals per hectare.

TABLE IV. — *Potatoes.*

		1916-1917	1917-1918	1918-1919
Area cultivated	ares	**621**	**707.39**	**489.61**

Potatoes for planting	»	15.00	15.00	81.00
Potatoes for livestock	»	8.00	10.00	19.00
Total net yield	»	4 366.16	8 964.54	17 920.83
Net yield per hectare	»	703.00	1 267.00	3 661.00
Net yield per 100 fr. of capital	»	23.88	34.90	81.02

It may be said that, in 1918, cereal crops gave from medium to good yields of grain and straw, but the production costs had heavily increased and a sa-

tisfactory profit was only made owing to the high prices guaranteed for that season (for wheat 74 and 71 fr., for oats 62 and 68 fr., for seed and market wheat and oats respectively ; for barley 60 fr.).

(4) *Potatoes.* — The data for this crop are shown in Table IV. The 1918 potato crop in Switzerland was generally better than had been expected. The same happened at Neuhof, where the results were the best of the three years, and, in addition, the sale prices were good. The production costs which, from an absolute standpoint, had increased, did not reach the figures of previous years when compared with the quantity harvested.

The capital invested in the potato crop yielded an interest of 81 % and the net yield per hectare was 3 661 fr., as against 703 fr. in 1916 and 1 267 fr. in 1917. These figures show the nature of the result given by the potato crop in 1918, a result which has helped the profit from the whole farm.

The crop gathered on the land rented from the ANGLIKER foundation was 20 540 kg. The total crop, including the small store of 1 200 kg. from the beginning of the season was utilised as follows :

Sale	67 760 kg	53,53 %
Household	14 000 »	11,06 »
Livestock	27 310 »	21,58 »
Seed tubers	17 530 »	13,83 »
Total	**126 610** kg	**100,00** %

It should be added that the many persons always available at Neuhof, constitute a very important factor as regards the extension of potato growing. In this respect Neuhof is more advantageously placed than the so called peasant farm.

(5) *Artificial meadows.* — These constitute a branch of the farm to which more attention will probably be paid at Neuhof in the future, when cultivation again will have to give way to some extent to intensive livestock production. The artificial meadows at Neuhof have covered the following areas :

416,00	ares	in	1916-1917
370,25	»	»	1917-1918
336,84	»	»	1918-1919

The profit from the forage grown is not calculated separately because it is included under livestock in the net profit account. However, the production costs have been ascertained, extended to the meadow and per 100 kg., are as follows :

	1916–1917 Fr.	1917–1918 Fr.	1918–1919 Fr.
Hay	9.84	—	6.17
Green fodder	1.97	1.26	1.42
Pasture	1.77	—	1.42

The production costs are lower than those usually accepted.

(6) *Natural meadows.* — The area occupied by natural meadows at Neuhof, of which they still form too large a part, was as follows :

In 1916-1917, from	1255,00 ares	or	37,6 % of the total area (except forestes)
In 1917-1918, »	1205,38 »	»	36,1 » » » » » »
In 1918-1919, »	1145,98 »	»	34,3 » » » » » »

The yields obtained from these areas are given below :

	1916–1917	1917–1918	1918–1919
Hay	15 680 kg.	28 735 kg.	22 285 kg.
Aftermath	—	2 550	5 330
Green fodder	163 650	115 985	219 755
Pasture	49 570	36 900	26 100
Total crop in starch values	26 026	30 472	42 303
» » » » » per hectare.	2 074	2 528	3 692

The artificial meadows show a considerable superiority over the natural meadows. The quantities of starch value produced per hectare of area were as follows :

	Artificial meadows	Natural meadows
1917–1918	3 714 kg.	2 528 kg.
1918–1919	5 681	3 692

Extended to the meadow, the production costs per 100 kg. were :

	1916-1917 Fr.	1917-1918 Fr.	1918-1919 Fr.
Itay	9.72	7.44	8.08
Aftermath	—	8.37	8.70
Green fodder	1.78	2.33	1.86
Pasture	1.49	2.01	1.85

The *dry fodder account*, which includes all the costs of the forage crop accounts, unites the costs relating to the natural and artificial meadows, as well as the purchases of fermented and standing hay. The costs are given below :

	1916-1917 Fr.	1917-1918 Fr.	1918-1919 Fr.
100 kg. of starch value without deducting the manurial value of the fodder	27.57	24.28	40.41
100 kg. of starch value after deducting the manurial value of the fodder	25.01	23.05	39.19
100 kg. of starch value of fermented hay	12.87	11.88	16.63
